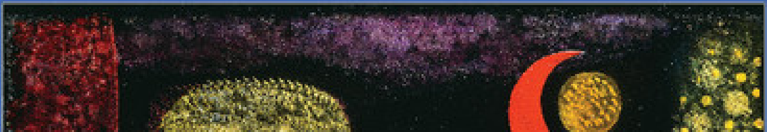
THE CAMBRIDGE DICTIONARY OF PHILOSOPHY

THIRD EDITION



GENERAL EDITOR

ROBERT AUDI

THE
CAMBRIDGE DICTIONARY
OF
PHILOSOPHY

THIRD EDITION

This is the most comprehensive dictionary of philosophical terms and thinkers available in English. Previously acclaimed as the most authoritative and accessible dictionary of philosophy in any language, it has been widely translated and has served both professional philosophers and students of philosophy worldwide. Written by a team of more than 550 experts – including more than 100 new to this third edition – the dictionary contains approximately 5,000 entries ranging from short definitions to full-length articles. It concisely defines terms, concretely illustrates ideas, and informatively describes philosophers. It is designed to facilitate the understanding of philosophy at all levels and in all fields.

Key features of this third edition:

- Some 500 new entries covering both Eastern and Western philosophy, as well as individual countries such as China, France, Germany, Italy, and Spain
- Increased coverage of such growing fields as ethics and philosophy of mind
- Scores of new intellectual portraits of leading contemporary thinkers
- Wider coverage of Continental philosophy
- Dozens of new concepts in cognitive science and other areas
- Enhanced cross-referencing to add context and to increase understanding
- Expansions of both text and index to facilitate research and browsing

Robert Audi is John A. O'Brien Professor of Philosophy at the University of Notre Dame. He is the author of numerous books and articles. His recent books include *Moral Perception* (2013); *Democratic Authority and the Separation of Church and State* (2011); *Rationality and Religious Commitment* (2011); *Epistemology: A Contemporary Introduction to the Theory of Knowledge* (2010); and *Moral Value and Human Diversity* (2007). Audi is a past president of the American Philosophical Association, a former editor of the *Journal of Philosophical Research*, and a former director of National Endowment for the Humanities Summer Seminars and Summer Institutes for college and university teachers.

CONTRIBUTORS

Mitchell Aboulafia (M.Ab.), *University of Houston, Clear Lake:* Mead

Frederick Adams (F.A.), *University of Delaware:* algorithm, bit, cybernetics, Dretske, information theory, mathematical function, non-monotonic logic

Marilyn McCord Adams (M.M.A.), *University of Oxford:* Anselm, Ockham, Ockham's razor

Robert M. Adams (R.M.A.), *Yale University:* agape, possible worlds, theodicy, transcendence

Laird Addis (L.A.), *University of Iowa:* holism, Mannheim, methodological holism

James W. Allard (J.W.A.), *Montana State University:* absolute; Alexander; Bosanquet; Bradley; Caird; Ferguson; Glanvill; Green; Mansel; Martineau; McCosh; McTaggart; More, Thomas; Price; Wilson

David Allison (D.Al.), *State University of New York, Stony Brook:* Saussure, structuralism, Teilhard de Chardin

William P. Alston (W.P.A.), *Syracuse University:* theory of appearing

Karl Ameriks (K.A.), *University of Notre Dame:* Kant

C. Anthony Anderson (C.A.A.), *University of California, Santa Barbara:* degree, intensional logic, Kaplan, substitutivity *salva veritate*, variable

David Leech Anderson (D.L.A.), *Illinois State University;* and Mario De Caro (M.D.C.), *University of Rome:* Putnam

Lanier Anderson (L.An.), *Stanford University*: Nehamas

Roger Ariew (R.Ar.), *Virginia Polytechnic Institute and State University*: crucial experiment, Duhem, Garber, Kuhn

David Armstrong (D.Ar.), *University of Texas, Austin:* Longinus, Lucretius, Marcus Aurelius

Denis G. Arnold (D.G.A.), *University of North Carolina, Charlotte:* business ethics

E.J. Ashworth (E.J.A.), *University of Waterloo:* Bruno, Campanella, Ficino, Fonseca, Gerson, Paracelsus, Pico della Mirandola

Margaret Atherton (M.At.), *University of Wisconsin, Milwaukee:* Astell; Cavendish; Cudworth, Damaris; Elizabeth of Bohemia; Shepherd; Wollstonecraft

Robin Attfield (R.A.), *Cardiff University:* Lucas

Bruce Aune (B.A.), *University of Massachusetts, Amherst:* fallibilism, problem of other minds

Edward Wilson Averill (E.W.A.), *Texas Tech University:* color, qualities

Jody Azzouni (J.A.), *Tufts University:* singularity

Kent Bach (K.B.), *San Francisco State University:* action verb, criterion, metalanguage, speech act theory, type-token distinction

Andrew Bailey (A.Ba.), *Yale NUS College, Singapore;* and **Joshua Rasmussen (J.R.),** *Azusa Pacific University:* pairing problem

Lynne Rudder Baker (L.R.B.), *University of Massachusetts, Amherst:* functionalism

Thomas R. Baldwin (T.R.B.), *University of York*: Anscombe, Strawson

Jon Barwise (J.Ba.), *Indiana University:* compactness theorem, infinitary logic

George Bealer (G.B.), *Yale University:* property

William Bechtel (W.B.), *University of California, San Diego:* cognitive science, connectionism

Lawrence C. Becker (L.C.B.), *College of William and Mary:* meritarian, meritocracy, prisoner's dilemma, situation ethics

Mark A. Bedau (M.A.B.), *Reed College:* artificial life

Ernst Behler (E.Beh.), *University of Washington:* Novalis, Schlegel

José A. Benardete (J.A.B.), *Syracuse University:* infinity

Ermanno Bencivenga (E.Ben.), *University of California, Irvine:* existential generalization, existential instantiation, free logic

Jan Berg (J.Be.), *Technische Universität München:* Bolzano

Michael Bergmann (M.Be.), *Purdue University:* skeptical theism

Robert L. Bernasconi (R.L.B.), *Pennsylvania State University:* Gadamer

Sven Bernecker (S.B.), *University of California, Irvine:* Bayesian epistemology

Bernard Berofsky (B.B.), *Columbia University:* determinism, necessitarianism

Rod Bertolet (R.B.), *Purdue University:* presupposition, private language argument, theory of descriptions, token-reflexive

Charles J. Beyer (C.J.B.), *State University of New York, Buffalo:* Montesquieu

Christian Beyer (C.B.), *University of Göttingen:* Føllesdal

Joseph Bien (J.Bi.), *University of Missouri, Columbia:* French personalism, Lukács, Ricoeur, Rousseau, Sorel

Joseph Bien (J.Bi.), *University of Missouri, Columbia;* and **Heinz Paetzold (H.P.),** *University of Hamburg:* Praxis school

Peg Birmingham (P.Bi.), *DePaul University:* Irigaray

Ivan Boh (I.Bo.), *Ohio State University: conditio sine qua non*, enthymeme, epicheirema, eristic, imposition, logical notation, obversion, Paul of Venice, Peter of Spain, polysyllogism, *pons asinorum*, Sheffer stroke, Sherwood, square of opposition, syllogism

James Bohman (J.Bo.), *St. Louis University:* Adorno, critical theory, *Erlebnis*, Frankfurt School, Habermas, hermeneutics, Horkheimer, Marcuse, Scheler, social action, *Verstehen*, Weber

Daniel Bonevac (D.Bo.), *University of Texas, Austin:* philosophy of logic

Laurence BonJour (L.B.), *University of Washington:* a priori, Broad, coherence theory of truth

William J. Bouwsma (W.J.B.), *University of California, Berkeley:* Calvin

Raymond D. Bradley (R.D.B.), *Simon Fraser University:* contingent, infinite regress argument, necessity

Myles Brand (M.B.), *Indiana University:* volition, wayward causal chain

Richard B. Brandt (R.B.B.), *University of Michigan:* Bentham, Ross

Michael E. Bratman (M.E.B.), *Stanford University:* intention

Stephen E. Braude (S.E.B.), *University of Maryland, Baltimore:* parapsychology

Daniel Breazeale (D.Br.), *University of Kentucky:* Fichte, Hölderlin, Jacobi, Reinhold, Schelling, Schiller

Angela Breitenbach (A.Bre.), *University of Cambridge:* O'Neill

Jason Bridges (J.B.), *University of Chicago:* Stroud

David O. Brink (D.O.B.), *University of California, San Diego:* emotivism, ethical constructivism, moral realism

Gordon G. Brittan, Jr. (G.G.B.), *Montana State University:* Enlightenment

Justin Broackes (J.Br.), *Brown University:* Murdoch

Dan W. Brock (D.W.B.), *Harvard University:* bioethics, utilitarianism

Aaron Bronfman (A.Br.) and Joseph Mendola (J.Me.), *University of Nebraska, Lincoln:* Gibbard

Jeffrey E. Brower (J.E.B.), *Purdue University:* matter

Bartosz Brozek (B.Br.), *Jagiellonian University, Kraków:* mindreading, rule-following

Anthony Brueckner (A.B.), *University of California, Santa Barbara:* lottery paradox, transcendental argument

Jeffrey Bub (J.Bub), *University of Maryland, College Park:* quantum logic

Lara Buchak (L.Bu.), *University of California, Berkeley:* belief updating, conditionalization, degrees of belief, Jeffrey conditionalization

Otavio Bueno (O.B.), *University of Miami:* van Fraassen

Ann E. Bumpus (A.E.B.), *Dartmouth College:* Thomson

Robert W. Burch (R.W.B.), *Texas A&M University:* antilogism, biconditional, conjunction, contraposition, contraries, contravalid, converse, disjunctive proposition, iff, inconsistent triad, logical product, negation, partition, sorites, truth table, truth-value

John Burgess (J.Bur.), *Princeton University:* forcing, independence results, tense logic

Arthur W. Burks (A.W.B.), *University of Michigan:* Babbage, computer theory, self-reproducing automaton, Turing machine, von Neumann

Panayot Butchvarov (P.Bu.), *University of Iowa:* conceptualism; first philosophy; Hartmann, N.; metaphysical realism; metaphysics; natural philosophy; substance; substantialism

Robert E. Butts (R.E.B.), *University of Western Ontario:* Bacon, Francis; Campbell; Eudoxus of Cnidus; functional dependence; Galileo Galilei; hypothetico-deductive method; incommensurability; Jevons; lawlike generalization; Priestley; Spencer; testability; theory-laden; Whewell

Marina Bykova (M.By.), *North Carolina State University:* Ilyenkov, Mamardashvili

Patrick Byrne (P.B.), *Boston College:* Lonergan

David Carr (D.C.), *Emory University:* philosophy of history

Noël Carroll (N.C.), *City University of New York:* Carlyle, Danto

Edward S. Casey (E.S.C.), *State University of New York, Stony Brook:* Jung

Victor Caston (V.C.), *University of Michigan:* Alexander of Aphrodisias, *energeia, lekton, phantasia*

Victor Caston (V.C.), *University of Michigan;* and **Stephen A. White (S.A.W.),** *University of Texas, Austin:* Andronicus of Rhodes, Antiochus of Ascalon

Albert Casullo (A.C.), *University of Nebraska, Lincoln:* bundle theory, compresence, identity of indiscernibles

Robert L. Causey (R.L.C.), *University of Texas, Austin:* magnitude, unity of science

Alan K.L. Chan (A.K.L.C.), *National University of Singapore:* Ge Hong, He Yan, Hsi K'ang, Neo-Daoism, *Po-hu tung, Qianfu Lun*, Ruan Ji, *xian, xingming*

Ruth Chang (R.Ch.), *Rutgers University:* incommensurable, Raz

Deen K. Chatterjee (D.K.C.), *University of Utah: abhinivesha, ahantā, ākāśa, anattāvāda, ārādhya, avidya*, dharma, *samādhi*, Vijñānavāda

Andrew Chignell (A.Ch.), *Cornell University:* Wood

Roderick M. Chisholm (R.M.C.), *Brown University:* Ducasse

Kelly J. Clark (K.J.C.), *Grand Valley State University:* Wolterstorff

E.J. Coffman (E.J.C.), *University of Tennessee:* luck, mind argument, warrant

Robin Collins (R.Co.), *Messiah College:* design plan, intelligent design

Brian P. Copenhaver (B.P.C.), *University of California, Riverside:* hermetism

John Corcoran (J.Cor.), *State University of New York, Buffalo:* ancestral, axiomatic method; Boole; borderline case; categoricity; Church; conditional; conjecture; convention T; converse, outer and inner; corresponding conditional; degenerate case; De Morgan; domain; ellipsis; laws of thought; limiting case; logical form; logical subject; material adequacy; mathematical analysis; modal transfer fallacy; omega; proof by recursion; recursive function; scheme; scope; Tarski; tautology; universe of discourse

John Cottingham (J.Cot.), *University of Reading: Cogito ergo sum*, Descartes

Roger Crisp (R.C.), *St. Anne's College, University of Oxford: agathon*, Anniceris, *aporia*, Arcesilaus of Pitane, *epagogē*, Eros, form, list theory, *logos, poiēsis*, rigorism, rule theory, well-being

Frederick J. Crosson (F.J.C.), *University of Notre Dame:* Newman, noetic, preexistence

Antonio S. Cua (A.S.C.), *The Catholic University of America: bi; bian; ch'üan; junzi; kung, szu; liangzhi; Li Chi; li-ch'i;* Lu Xiangshan; *rong, ru; sheng; tianren heyi;* Wang Yangming*;* Xunzi; *zhi*[1]*; zhixing heyi*

Phillip D. Cummins (P.D.C.), *University of Iowa:* Bayle

Martin Curd (M.C.), *Purdue University:* Boltzmann, energeticism, Maxwell, Schrödinger

Adam Cureton (A.Cu.), *University of Tennessee:* Hill

Andrew Cutrofello (A.Cut.), *Loyola University of Chicago:* Žižek

Stephen Darwall (S.Dar.), *Yale University:* Butler, Frankena, respect

Paul Sheldon Davies (P.S.D.), *College of William and Mary:* Lycan

Wayne A. Davis (W.A.D.), *Georgetown University:* analytic-synthetic distinction; causal theory of action; counterfactuals; desire; inferential knowledge; Lewis, D. K.; semantic relativism

Timothy Joseph Day (T.J.D.), *University of Alabama, Birmingham:* logical indicator, operator theory of adverbs

Claudio de Almeida (C.d.A.), *Pontifical Catholic University of Rio Grande do Sul:* contextualism, G. E. Moore shift, Moore's paradox, pragmatic encroachment

Mario De Caro (M.D.C.), *University of Rome;* and **David Macarthur (D.M.),** *University of Sydney:* liberal naturalism

Mario De Caro (M.D.C.), *University of Rome;* and **Stefano Poggi (S.D.),** *Università di Firenze:* Italian philosophy, Renaissance philosophy

John Deigh (J.D.), *University of Texas, Austin:* ethics, Gert, motivational internalism

C.F. Delaney (C.F.D.), *University of Notre Dame:* American philosophy, Critical Realism, Dewey, hypostasis, instrumentalism, New Realism, personalism, wisdom

Daniel C. Dennett (D.C.D.), *Tufts University:* homunculus, intentionality, Mentalese, mentalism, topic-neutral

Michael R. DePaul (M.R.D.), *University of Notre Dame:* coherentism, Fumerton, reflective equilibrium

Michael Detlefsen (M.D.), *University of Notre Dame:* Brouwer, Gödel's incompleteness theorems, Hilbert, Hilbert's Program, metamathematics

Daniel Trent Devereux (D.T.D.), *University of Virginia:* eudaimonism, Socratic intellectualism

Philip E. Devine (P.E.D.), *Providence College:* euthanasia, principle of double effect

John M. Dillon (J.M.D.), *Trinity College, Dublin:* Alexandrian School, Ammonius Saccas, commentaries on Aristotle, commentaries on Plato, Damascius, Johannes Philoponus, Middle Platonism, Neoplatonism, Numenius of Apamea, Plotinus

Martin C. Dillon (M.C.D.), *Binghamton University:* Derrida, *différence*

Robert DiSalle (R.D.), *University of Western Ontario:* Helmholtz, relativity, space, space-time

Mary Domski (M.Do.), *University of New Mexico:* Friedman

Alan Donagan (A.D.), *California Institute of Technology:* Collingwood

Paul Draper (P.D.), *Purdue University:* Rowe

Fred Dretske (F.D.), *Stanford University:* perception, sensibilia

Mircea Dumitru (M.Du.), *University of Bucharest:* Fine

Wilhelm Dupré (W.D.), *The Catholic University of the Netherlands:* Jaspers

Gerald Dworkin (G.D.), *University of California, Davis:* paternalism, positive and negative freedom

John Earman (J.Ea.) and **Richard M. Gale (R.M.Ga.),** *University of Pittsburgh:* time

Ellery Eells (E.Ee.), *University of Wisconsin, Madison:* equiprobable, principle of indifference, probability, regression analysis

Catherine Z. Elgin (C.Z.E.), *Harvard University:* Goodman

Berent Enç (B.E.), *University of Wisconsin, Madison:* motivational explanation, paradigm, paradigm case argument, plurality of causes

Ronald P. Endicott (R.P.E.), *Arkansas State University:* Churchland, Patricia; Churchland, Paul

Edward Erwin (E.Er.), *University of Miami:* philosophy of psychology

John Etchemendy (J.Et.), *Stanford University:* logical consequence, paradox, satisfaction, semantic paradoxes, set-theoretic paradoxes

C. Stephen Evans (C.S.E.), *Baylor University: Angst*, Kierkegaard

Susan L. Feagin (S.L.F.), *Temple University:* aesthetic attitude, aesthetic property, aesthetics, beauty, expression theory of art, institutional theory of art, sublime

Solomon Feferman (S.Fe.), *Stanford University:* ordinal logic, reflection principles

Richard Feldman (R.Fe.), *University of Rochester:* epistemic privacy, evidence, knowledge by acquaintance, knowledge *de re*

Arthur Fine (A.F.), *University of Washington:* Einstein, quantum mechanics

Maurice A. Finocchiaro (M.A.F.), *University of Nevada, Las Vegas:* Gramsci, Mosca

William FitzPatrick (W.F.), *University of Rochester:* harm principle, is-ought gap, ought-implies-can principle, sensibility theory, social intuitionism

Richard E. Flathman (R.E.F.), *Johns Hopkins University:* Arendt, Oakeshott, political theory

Gvozden Flego (G.Fl.), *University of Zagreb:* Blondel, Fourier, Proudhon

Richard Foley (R.Fo.), *New York University:* analysis, pragmatic contradiction, subjectivism, voluntarism

Graeme Forbes (G.Fo.), *Tulane University:* modal logic, operator, order, ordering, reality

Rainer Forst (R.F.), *Goethe University:* toleration

Malcolm R. Forster (M.R.F.), *University of Wisconsin, Madison:* curve-fitting problem

Daniel Fouke (D.F.), *University of Dayton:* Pascal

Patrick Francken (P.F.), *Illinois State University:* time slice

Samuel Freeman (S.Fr.), *University of Pennsylvania:* Rawls, Scanlon

Elizabeth Fricker (E.F.), *Magdalen College, University of Oxford:* testimony, trust

Miranda Fricker (M.F.), *University of Sheffield:* feminist epistemology

Michael Friedman (M.Fr.), *Stanford University:* Hempel

Michael Fuerstein (M.Fu.), *St. Olaf College:* Kitcher

Richard A. Fumerton (R.A.F.), *University of Iowa:* Ayer, logical positivism, phenomenalism, protocol statement

Alan Gabbey (A.G.), *Barnard College:* Boyle; Cambridge Platonists; More, Henry

Pieranna Garavaso (P.Gar.), *University of Minnesota, Morris:* Beccaria, Cajetan, Gentile, Gioberti, Joachim of Floris, Labriola, Marsilius of Padua, Medina, Pomponazzi, Rosmini-Serbati, Telesio, Valla, Vanini, Zabarella

Daniel Garber (D.Garb.), *Princeton University:* Cordemoy, Geulincx, Goclenius, Harman, La Forge, mode, rationalism

Jorge L.A. Garcia (J.L.A.G.), *Boston College:* cardinal virtues, racism, virtue ethics

Robert K. Garcia (R.K.G.), *Texas A&M University:* food ethics, trope

Don Garrett (D.Garr.), *New York University:* Spinoza

Philip Gasper (P.Gas.), *College of Notre Dame:* anti-realism, social constructivism

Gerald Gaus (G.Gau.), *University of Arizona:* Nash equilibrium, public reason

Berys Gaut (B.Ga.), *University of Saint Andrews:* consequentialism, creativity, depiction, fiction, intentional fallacy

Bernard Gert (B.Ge.), *Dartmouth College:* applied ethics, Hobbes, morality, rationality, supererogation

Roger F. Gibson (R.F.G.), *Washington University:* corners, indeterminacy of translation, oblique context, ontological commitment, quantifying in, Quine

Cody Gilmore (C.Gi.), *University of California, Davis:* constitution, pluriverse, presentism, time travel

Carl Ginet (C.G.), *Cornell University:* memory, paradox of analysis

Alan H. Goldman (A.H.G.), *University of Miami:* privileged access

Alvin I. Goldman (A.I.G.), *Rutgers University:* naturalistic epistemology, reliabilism, social epistemology

Alfonso Gömez-Lobo (A.G.-L.), *Georgetown University: hexis*, Peripatetic School

Lenn E. Goodman (L.E.G.), *Vanderbilt University:* al-Rāzī, Averroes, Avicenna, Ibn Daud, Maimonides, Miskawayh, Saadiah Gaon

Robert M. Gordon (R.M.G.), *University of Missouri, St. Louis:* emotion, empathy, James-Lange theory, simulation theory

Stefan Gosepath (S.G.), *Free University of Berlin:* Tugendhat

Jorge J.E. Gracia (J.J.E.G.), *State University of New York, Buffalo:* Bañez, Gracián y Morales, individuation, John of Saint Thomas, Latin American philosophy, Mariana, Molina, Ortega y Gasset, *principium individuationis*, Soto, Suárez, Toletus, Unamuno, Vázquez, Vitoria

Daniel W. Graham (D.W.G.), *Brigham Young University:* Anaxagoras, Anaximander, Anaximenes of Miletus, ancient atomism, *apeiron*, Democritus, Empedocles, Heraclitus, Leucippus, Milesians, pre-Socratics, Thales

George A. Graham (G.A.G.), *Georgia State University:* associationism, attribution theory, behavior therapy, cognitive dissonance, conditioning, intervening variable, poverty of the stimulus, redintegration, sensorium, synaesthesia

Peter J. Graham (P.J.Gr.), *University of California, Riverside:* Burge, content, disjunctivism, intentionalism, representationalism

Richard E. Grandy (R.E.G.), *Rice University:* Grice, Löwenheim-Skolem theorem, psycholinguistics

I. Grattan-Guinness (I.G.-G.), *Middlesex Polytechnic University:* calculus, Euclidean geometry, non-Euclidean geometry, Peano postulates

John Greco (J.G.), *St. Louis University:* inference to the best explanation, value problem, virtue epistemology

Philip T. Grier (P.T.G.), *Dickinson College:* Il’in, Kropotkin, Shpet

Nicholas Griffin (N.G.), *McMaster University:* emotive conjugation, mnemic causation

Nicholas Griffin (N.G.), *McMaster University;* and **David B. Martens (D.B.M.),** *Mount Royal College:* Russell

David A. Griffiths (D.A.G.), *University of Victoria:* Leroux

Paul J. Griffiths (P.J.G.), *Duke University: abhidharma, ālaya-vijñāna, bhavanga, citta-mātra, dravyasat, jhāna, nirodha-samāpatti, samanantara-pratyaya, samatha, śūnyatā, vāsanā, vijñapti, vipassanā*

Stephen R. Grimm (S.R.G.), *Fordham University:* understanding

Charles L. Griswold, Jr. (C.L.G.), *Boston University:* Smith

Charles B. Guignon (C.B.G.), *University of Vermont:* Heidegger

Pete A.Y. Gunter (P.A.Y.G.), *University of North Texas:* Bergson

Dimitri Gutas (D.Gu.), *Yale University:* Arabic philosophy, Ibn Khaldūn, Sufism

Gary Gutting (G.G.), *University of Notre Dame:* Bachelard; Badiou; Canguilhem; Foucault; Lacan; MacIntyre; Rorty; Taylor, Charles; Voltaire

Paul Guyer (P.Gu.), *Brown University:* Baumgarten, Cavell, Wolff

Kwame Gyekye (K.G.), *University of Ghana:* African philosophy

Oscar A. Haac (O.A.H.), *New York City:* Condillac, Constant, Cousin

Raul Hakli (R.Ha.), *University of Helsinki:* collective belief

Raul Hakli (R.Ha.) and **Pekka Mäkelä (P.Mä.),** *University of Helsinki:* social ontology

Michael Hallett (M.H.), *McGill University:* Cantor, Dedekind, Skolem

Edward C. Halper (E.C.H.), *University of Georgia: aitia, autarkia, dianoia,* elenchus, *noûs,* one-many problem, one over many, *ousia, telos*

Jean Hampton (J.Ham.), *University of Arizona:* contractarianism, social contract

R. James Hankinson (R.J.H.), *University of Texas, Austin:* Galen, Hippocrates

K.R. Hanley (K.R.H.), *Le Moyne College:* Marcel

Russell Hardin (R.Har.), *New York University:* game theory, Pareto efficiency, voting paradox

Robert M. Harnish (R.M.H.), *University of Arizona:* Searle

William Harper (W.Har.), *University of Western Ontario:* natural kind

David Harrah (D.H.), *University of California, Riverside:* axiom of consistency, cut-elimination theorem, erotetic, fuzzy set, tonk

Kevin Hart (K.H.), *University of Virginia:* Marion

Ali Hasan (A.H.), *University of Iowa:* BonJour

William Hasker (W.Has.), *Huntington College:* evidentialism, justification by faith, middle knowledge, open theism, self-referential incoherence

John Haugeland (J.Hau.), *University of Pittsburgh:* artificial intelligence

Roger Hausheer (R.Hau.), *University of Bradford:* Berlin

William Heald (W.He.), *University of Iowa:* Bergmann

Peter Heath (P.He.), *University of Virginia:* Austin, J. L.; Carroll

Richard Heck (R.E.), *Brown University:* Wright, Crispin

John F. Heil (J.F.H.), *Washington University:* analytic philosophy, awareness, blindsight, Dennett, direct realism, doxastic, Kim, mental causation, Molyneux question, ordinary language philosophy, power, preanalytic, pro attitude, prototype theory, pseudohallucination, reasons for belief, subdoxastic, Twin-Earth

Vincent F. Hendricks (V.F.H.), *University of Copenhagen:* formal epistemology

Stephen Hetherington (S.He.), *University of New South Wales:* Australasian philosophy

Francis Heylighen (F.H.), *Free University of Brussels;* and **Cliff Joslyn (C.J.),** *State University of New York, Binghamton:* systems theory

Kathleen Marie Higgins (K.M.H.), *University of Texas, Austin:* Schopenhauer

Risto Hilpinen (R.Hi.), *University of Miami and University of Turku:* artifact, epistemic logic, epistemic principle, KK-thesis, Peirce, tychism

Harold T. Hodes (H.T.H.), *Cornell University:* degree of unsolvability, hierarchy, lambda-calculus, logicism

Joshua Hoffman (J.Ho.) and **Gary Rosenkrantz (G.Ro.),** *University of North Carolina, Greensboro:* Boscovich, life, mereology, organism, perdurance

Alan Holland (A.Ho.), *University of Lancaster:* environmental philosophy

Robert L. Holmes (R.L.H.), *University of Rochester:* Gandhi, just war theory, nonviolence, pacifism, violence

Richard Holton (R.H.), *University of Cambridge:* Williamson

Brad W. Hooker (B.W.H.), *University of Reading:* ascriptivism, Brandt, casuistry, descriptivism, Hare, justice, prescriptivism, sanction

Terence E. Horgan (T.E.H.), *University of Arizona:* folk psychology, supervenience

Tamara Horowitz (T.H.), *University of Pittsburgh:* entropy, stochastic process

Paul Horwich (P.Hor.), *New York University:* truth

Vittorio Hösle (V.H.), *University of Notre Dame:* German philosophy

Paul Hoβfeld (P.Hoβ.), *Albertus Magnus Institut:* Albertus Magnus

Daniel Howard-Snyder (D.H.-S.), *Western Washington University:* faith

Frances Howard-Snyder (F.H.-S.), *Western Washington University:* Bennett, ethics of love

Anne Hudson (A.Hu.), *Lady Margaret Hall, University of Oxford:* Wyclif

Deal W. Hudson (D.W.H.), *Fordham University:* Gilson, Maritain, Mercier, Neo-Thomism

Carl A. Huffman (C.A.H.), *DePauw University:* Archytas, Philolaus, Pythagoras

David L. Hull (D.L.H.), *Northwestern University:* Darwinism, mechanistic explanation, Mendel, philosophy of biology, teleology

Patricia Huntington (P.Hu.), *Loyola University of Chicago:* Kristeva

Thomas Hurka (T.Hu.), *University of Toronto:* Rashdall

Paul Hurley (P.H.), *Claremont McKenna College:* demandingness, paradox of deontology

Rosalind Hursthouse (R.Hu.), *University of Auckland:* Foot

Guillermo Hurtado (G.H.), *Instituto de Investigaciones Filosóficas:* Spanish philosophy

Ronald E. Hustwit (R.E.H.), *College of Wooster:* Bouwsma

Sarah Hutton (S.H.), *Aberystwyth University:* Cockburn, Conway

Jonathan Jenkins Ichikawa (J.J.I.), *University of British Columbia:* dreaming

Harry A. Ide (H.A.I.), *University of Nebraska, Lincoln:* Cynics, Cyrenaics, Sophists, thema

David Ingram (D.I.), *Loyola University of Chicago:* Apel, Honneth

Philip J. Ivanhoe (P.J.I.), *City University of Hong Kong:* Cheng Hao, Cheng Yi; *ching;* Dai Zhen; Daoism; Guo Xiang; *hsin*^{2}; Huang-Lao; *I-Ching; li*^{1}; *qi;* Shao Yong; *shen;* Wang Bi; Wang Fuzhi; *xu;* Yan Yuan; Zhang Xuecheng; Zhang Zai, Zhou Dunyi; *ziran*

Alfred L. Ivry (A.L.I.), *New York University:* al-Fārābī, al-Ghazālī, cabala, Ibn Gabirol, Jewish philosophy

Frank Jackson (F.J.), *Australian National University:* two-dimensional semantics

Dale Jacquette (D.J.), *University of Bern:* abstract entity, act-object psychology, Brentano, extensionalism, haecceity, impredicative definition, Meinong, subject-object dichotomy, use-mention distinction

Joseph Jedwab (J.Jed.), *Kutztown University:* atonement, grace, natural reason

Richard Jeffrey (R.J.), *Princeton University:* Bayes's theorem, computability, decision theory, Ramsey

David Alan Johnson (D.A.J.), *Yeshiva University:* Bayesian rationality, doomsday argument, envelope paradox, grue paradox, qualitative predicate

Edward Johnson (E.J.), *University of New Orleans:* death, moral status, personhood

Mark D. Jordan (M.D.J.), *Harvard University:* Ambrose, Augustine, Bernard of Chartres, Eckhart, Lull, patristic authors, Teresa of Ávila, William of Moerbeke

Richard Joyce (R.Jo.), *Victoria University of Wellington:* evolutionary arguments, evolutionary ethics

Hwa Yol Jung (H.Y.J.), *Moravian College:* Bakhtin, transversality

Robert Hillary Kane (R.H.K.), *University of Texas, Austin:* Arminius, Bloch, book of life, Lequier, *liberum arbitrium*, principle of insufficient reason, principle of plenitude, Renouvier, Socinianism

Tomis Kapitan (T.K.), *Northern Illinois University:* free will problem, guise theory, practition, quasi-indicator, self-determination

Jacquelyn Ann K. Kegley (J.A.K.K.), *California State University, Bakersfield:* Royce

James A. Keller (J.A.K.), *Wofford College:* process theology, thought experiment, unity in diversity

Ralph Kennedy (R.Ke.), *Wake Forest University:* conjunctivity, cumulative case argument, Dutch book, Dutch book argument, Dutch book theorem, enantiamorphs, gambler's fallacy, homomorphism, inferentialism, intellectualism, problem of the speckled hen, self-presenting

Sergei Khoruzhii (S.Kh.), *Steklov Institute of Mathematics:* Florenski

Jaegwon Kim (J.K.), *Brown University:* causal law, causation, explanation

Yersu Kim (Y.K.), *Seoul National University:* Korean philosophy

Nathan L. King (N.L.K.), *Whitworth College:* philosophical theology, religious epistemology

Patricia Kitcher (P.K.), *Columbia University:* Beattie

Peter D. Klein (P.D.K.), *Rutgers University:* certainty, closure, infinitism

E.D. Klemke (E.D.K.), *Iowa State University:* Moore

Virginia Klenk (V.K.), *Moorhead State University:* axiom of comprehension, comprehension, connected, copula, counterinstance, lexical ordering, normal form, order type omega, sentential connective

George L. Kline (G.L.K.), *Bryn Mawr College:* Bakunin, Berdyaev, Herzen, Russian nihilism, Russian philosophy, Solovyov

Christian Klotz (C.K.), *Federal University, Goias, Brazil:* Henrich

Simo Knuuttila (S.K.), *University of Helsinki:* future contingents

Joseph J. Kockelmans (J.J.K.), *Pennsylvania State University:* Continental philosophy, phenomenology

Konstantin Kolenda (K.K.), *Rice University:* humanism

Sebastian Tomasz Kołodziejczyk (S.T.Ko.), *Jagiellonian University:* Woleński

Isaac Kramnick (I.K.), *Cornell University:* Burke

Richard Kraut (R.Kr.), *Northwestern University:* Plato, Socrates

Fred Kroon (F.K.), *University of Auckland:* Jackson

Manfred Kuehn (M.K.), *Boston University:* acosmism, Haeckel, Hamann, Hamilton, Herbart, Lambert, Maimon, Reimarus, Schulze, Tetens, Vaihinger

Steven T. Kuhn (S.T.K.), *Georgetown University:* decidability, deduction theorem, formalism, formalize, formal language, ideal language, is, Kripke semantics, sortal predicate, truth-value semantics

Henry E. Kyburg, Jr. (H.E.K.), *University of Rochester:* Carnap

John Lachs (J.La.), *Vanderbilt University:* Santayana

Jennifer Lackey (J.Lac), *Northwestern University:* disagreement

Stephen E. Lahey (S.E.L.), *Le Moyne College:* insolubilia, *obligationes*, *sophismata*, topics

Andrea Lavazza (A.La.), *Centro Universitario Internazionale, Arezzo, Italy:* journalistic ethics

Thomas H. Leahey (T.H.L.), *Virginia Commonwealth University:* Bain, camera obscura, faculty psychology, Fechner, Hartley, hologram, ideo-motor action, Köhler, Lewin, McDougall, Stout, Ward, Wundt

Joo Heung Lee (J.H.L.), *Wright College:* Bataille

Keith Lehrer (K.L.), *University of Arizona:* Reid

Dorothy Leland (D.Le.), *Purdue University:* embodiment

Noah M. Lemos (N.M.L.), *College of William and Mary:* false pleasure; Perry, Ralph Barton; value; value theory

Ernest LePore (E.L.), *Rutgers University:* Davidson, *de dicto*, holism, principle of verifiability, semantic holism, verificationism

Sarah-Jane Leslie (S.-J.L.), *Princeton University:* generics

Isaac Levi (I.L.), *Columbia University:* Bernoulli's theorem; Nagel, Ernest; reduction sentence; statistical explanation

Andrew Levine (A.L.), *University of Wisconsin, Madison:* Althusser

Alan E. Lewis (A.E.L.), *Austin Presbyterian Theological Seminary:* Arianism, Athanasius, Clement of Alexandria, henotheism, *homoousios*, Montanism, Pelagianism, Tertullian

Daniel E. Little (D.E.L.), *University of Michigan, Dearborn:* ethnography, ethnology, ethnomethodology, philosophy of the social sciences

Shu-hsien Liu (S.-h.L.), *Chinese University of Hong Kong: cheng;* Chen Xianzheng; Chinese philosophy; *daotong; daoxin, renxin;* Dong Zhongshu; Fang; Feng Youlan; Han Yu; *hsing-erh-shang;* Huang Zongxi; Hu Hong; Hu Shi; Jia Yi; Kang Youwei; Liang Qichao; Liang Shuming; Li Ao; Liu Shaoqi; Liu Zongzhou; *liyifenshu;* Mao Zedong; Mou Zongsan; Neo-Confucianism; *qian, kun;* Qian Mu; *shan, e;* Sun Yat-sen; *taiji;* Tang Junyi; Tan Sitong; *t'i, yung; tianli, renyu*; Wang Chong; Xiong Shili; Xu Fuguan; Yang Xiong; *you, wu;* Zhu Xi

Shu-hsien Liu (S.-h.L.), *Chinese University of Hong Kong*, and **Alan K.L. Chan (A.K.L.C.),** *National University of Singapore:* Jiao Hong

Brian Loar (B.L.), *Rutgers University:* meaning

Lawrence B. Lombard (L.B.L.), *Wayne State University:* event

John Longeway (J.Lo.), *University of Wisconsin, Parkside:* Adelard of Bath, Albert of Saxony, Boehme, Erigena, Fludd, Gregory I, John of Damascus, Marsilius of Inghen, Nemesius of Emesa, Nicholas of Cusa, *Nihil ex nihilo fit, sensus communis,* terminist logic, William of Alnwick, William of Auvergne

Dominic McIver Lopes (D.Lo.), *University of British Columbia:* computer art

Michael J. Loux (M.J.L.), *University of Notre Dame:* essentialism

E.J. Lowe (E.J.L.), *University of Durham:* Armstrong, brute, Dummett, identity conditions, truthmaker

Steven Luper (S.L.), *Trinity University, San Antonio:* Nozick

Eugene C. Luschei (E.C.L.), *Brown University:* Kotarbiński, Leśniewski, Polish logic

William G. Lycan (W.G.L.), *University of North Carolina, Chapel Hill:* philosophy of language

David Lyons (D.Ly.), *Boston University:* Hart

David Macarthur (D.Macar.), *University of Sydney:* neopragmatism

Danielle Macbeth (D.Mac.), *Haverford College:* McDowell

Scott MacDonald (S.Ma.), *Cornell University:* Boethius, Kretzmann, Peter Lombard, transcendentals

Jacob L. Mackey (J.L.M.), *City University of New York:* Philodemus of Gadara

Louis H. Mackey (L.H.M.), *University of Texas, Austin:* literary theory, philosophy of literature

Penelope Mackie (P.Mac.), *University of Birmingham:* compossible, counterpart theory, organic, organicism, process-product ambiguity

Edward H. Madden (E.H.M.), *University of Kentucky:* Thoreau; transcendentalism; Wright, Chauncey

Penelope Maddy (P.Mad.), *University of California, Irvine:* class, complementary class, continuum problem, maximal consistent set, Schröder-Bernstein theorem, set theory, transfinite number

G.B. Madison (G.B.M.), *McMaster University:* Merleau-Ponty

Bernd Magnus (B.M.), *University of California, Riverside:* postmodern

Pekka Mäkelä (P.Mä), *University of Helsinki:* Tuomela

Rudolf A. Makkreel (R.A.M.), *Emory University:* Dilthey, *Einfühlung*

David Manley (D.Ma.), *University of Michigan, Ann Arbor:* fictionalism, fink

William E. Mann (W.E.M.), *University of Vermont:* accidentalism, Bernard of Clairvaux, *concursus dei, dictum de omni et nullo*, emanationism, eternal return, *infima species*, mystical experience, mysticism, *Nihil est in intellectu quod non prius fuerit in sensu*, paradoxes of omnipotence, Porphyry, soul, survival, tree of Porphyry

Vladimir Marchenkov (V.M.), *Ohio University:* Losev

Peter Markie (P.Mar.), *University of Missouri, Columbia:* egocentric particular, egocentric predicament

Jean-Pierre Marquis (J.-P.M.), *University of Montreal:* category theory

Ausonio Marras (A.M.), *University of Western Ontario:* behaviorism

Mike W. Martin (M.W.M.), *Chapman College:* bad faith, false consciousness, institution, professional ethics, self-deception, vital lie

A.P. Martinich (A.P.M.), *University of Texas, Austin:* distribution, *ens a se, ens rationis, ens realissimum, fundamentum divisionis, notum per se, obiectum quo*, pantheism, *Pantheismusstreit*, reism, *rerum natura, terminus a quo, theologia naturalis*, theosophy

William L. McBride (W.L.M.), *Purdue University:* existentialism, Marx, Marxism

David McCabe (D.Mc.), *Colgate University:* cosmopolitanism

Storrs McCall (S.Mc.), *McGill University:* Łukasiewicz

Hugh J. McCann (H.J.M.), *Texas A&M University:* action theory, practical reason, practical reasoning, reasons for action

Robert N. McCauley (R.N.Mc.), *Emory University:* evolutionary psychology

John J. McDermott (J.J.M.), *Texas A&M University:* Emerson, James, specious present

Sarah McGrath (S.McG.), *Princeton University:* expertise

Ralph McInerny (R.M.), *University of Notre Dame:* neo-Scholasticism, *philosophia perennis*, potency, synderesis

Daniel J. McKaughan (D.J.M.), *Boston University:* constructive empiricism, counterintuitive, empirical adequacy, hope

Thomas McKay (T.M.), *Syracuse University:* connotation, denotation, indirect discourse, propositional opacity, referentially transparent

Michael McKinsey (M.M.), *Wayne State University:* anaphora, implicature, indexical

Brian P. McLaughlin (B.P.M.), *Rutgers University:* philosophy of mind

Ernan McMullin (E.M.), *University of Notre Dame:* Kepler, Mach, Poincaré

Anthonie Meijers (A.Mei.), *Technische Universiteit Eindhoven:* Baker, philosophy of technology

Jack W. Meiland (J.W.M.), *University of Michigan:* category, category mistake, Ryle

William Jason Melanson (W.J.M.), *University of Nebraska, Omaha:* conviction, internal question, revisability

Alfred R. Mele (A.R.M.), *Florida State University:* accidie, *akrasia*, control, extrinsic desire, Frankfurt cases, Libet experiments, motivation, plan, rationalization, Socratic paradoxes, theoretical reason, toxin puzzle

Joseph R. Mendola (J.R.M.), *University of Nebraska, Lincoln:* informed consent, moral psychology, rational psychology

Christopher Menzel (C.M.), *Texas A&M University:* alethic modalities, type theory

Michael J. Meyer (M.J.M.), *Santa Clara University:* character, dignity, Percival

Christian B. Miller (C.B.M.), *Wake Forest University:* Cornell Realism, Humean theory of motivation, response-dependence, situationism, trait

David W. Miller (D.W.M.), *University of Warwick:* demarcation, Popper

Peter Millican (P.M.), *Hertford College, University of Oxford:* Mackie

Robert N. Minor (R.N.Mi.), *University of Kansas: ādhyātman, ahamkāra, ahimsā, akśara*, avatar, *bhakti, samsāra, sat/chit/ānanda*, Vishnu

Phillip Mitsis (P.Mi.), *Cornell University:* Cicero

James A. Montmarquet (J.A.M.), *Tennessee State University:* hedonism, perfectionism, *summum bonum*

Michael S. Moore (M.S.M.), *University of Illinois:* basic norm, cheapest-cost avoider, critical legal studies, *mens rea*, M'Naghten rule, punishment, telishment

Tim Moore (T.Mo.), *Hong Kong University;* and **Alan Schrift (A.S.),** *Grinnell College:* French philosophy

Benjamin Morison (B.Mor.), *Princeton University:* Cooper

Donald R. Morrison (D.R.M.), *Rice University:* Xenophon

Stephen J. Morse (S.J.M.), *University of Pennsylvania:* diminished capacity, neurolaw

Paul K. Moser (P.K.M.), *Loyola University of Chicago:* belief; epistemic regress argument; epistemology; foundationalism; hiddenness, divine; irrationality; metaphilosophy, pretheoretical

Alexander P.D. Mourelatos (A.P.D.M.), *University of Texas, Austin:* Abderites, Eleatic School, homoeomerous, hylozoism, Ionian philosophy, Melissus of Samos, Orphism, Parmenides, Xenophanes

Ian Mueller (I.M.), *University of Chicago*: Celsus, doxographers, Hypatia, Simplicius

James Bernard Murphy (J.B.M.), *Dartmouth College:* common good, semiosis, subsidiarity

Mark C. Murphy (M.C.M.), *Georgetown University:* new natural law theory

Steven Nadler (S.N.), *University of Wisconsin, Madison:* Arnauld, Malebranche, occasionalism, *Port-Royal Logic*

Jan Narveson (J.Na.), *University of Waterloo:* social philosophy

Alan Nelson (A.N.), *University of North Carolina, Chapel Hill:* Arrow's paradox; ideal market; Keynes; Mill, James; perfect competition; production theory; social choice theory

Jerome Neu (J.Ne.), *University of California, Santa Cruz:* Freud

Samuel Newlands (S.New.), *University of Notre Dame:* Adams, Robert Merrihew

Kai Nielsen (K.N.), *University of Calgary:* Engels, historicism

Ilkka Niiniluoto (I.N.), *University of Helsinki:* covering law model, Finnish philosophy, truthlikeness, von Wright

Carlos G. Noreña (C.G.Nore.), *University of California, Santa Cruz:* Vives

Calvin G. Normore (C.G.Norm.), *University of California, Los Angeles:* Kilwardby, Scholasticism, Siger of Brabant

David Fate Norton (D.F.N.), *McGill University:* Hume

Nikolaj Nottelmann (N.N.), *University of Southern Denmark:* acceptance, ignorance, Nordic philosophy

Donald Nute (D.N.), *University of Georgia:* default logic, defeasibility, intension

David S. Oderberg (D.S.O.), *University of Reading:* Geach

Steve Odin (S.O.), *University of Hawaii:* Japanese philosophy

Michael O'Rourke (M.O.), *Michigan State University:* Perry, John

Willard G. Oxtoby (W.G.O.), *University of Toronto:* Zoroastrianism

Heinz Paetzold (H.P.), *University of Hamburg:* Bodin, Erasmus, Helvétius

George S. Pappas (G.S.P.), *Ohio State University:* basing relation, Berkeley, idea, immaterialism

Anthony J. Parel (A.J.P.), *University of Calgary:* Machiavelli

Lydia Patton (L.Pa.), *Virginia Polytechnic Institute and State University:* Hacking

R.P. Peerenboom (R.P.P.) and **Roger T. Ames (R.T.A.),** *University of Hawaii:* Chinese Legalism; Guanzi; *Huainanzi;* Hui Shi; Liezi; *Lushichunqiu;* Mohism; School of Names; Shang Yang; Shen Buhai; Shen Dao; *shi*^{1}; *shi*^{2}; *shu*^{1}; Song Xing; *wuxing;* Xu Xing; Yang Zhu; yin, yang; Zou Yan

Francis Jeffry Pelletier (F.J.P.) and **István Berkeley (I.Be.),** *University of Alberta:* vagueness

Adriaan T. Peperzak (A.T.P.), *Loyola University of Chicago:* Levinas

Derk Pereboom (D.P.), *Cornell University:* Adams, Marilyn McCord

Jaroslav Peregrin (J.P.), *Institute of Philosophy, Czech Republic:* Brandom

Glen Pettigrove (G.P.), *University of Auckland:* forgiveness

Philip Pettit (P.P.), *Princeton University:* Smart

Edmund L. Pincoffs (E.L.P.), *University of Texas, Austin:* Austin, John

Andrew Pinsent (A.Pi.), *Ian Ramsey Centre for Science and Religion, University of Oxford:* ratiocination, second-person relatedness, Stump

Robert B. Pippin (R.B.P.), *University of Chicago:* Hegel

Alvin Plantinga (A.P.), *University of Notre Dame:* Alston

Louis P. Pojman (L.P.P.), *United States Military Academy, West Point:* agnoiology, agnosticism, apocatastasis, atheism, Basilides, Buchmanism, gnosticism, Gregory of Nyssa, meliorism, Origen, relativism, Valentinus, Westermarck

Richard H. Popkin (R.H.P.), *University of California, Los Angeles:* Charron, HaLevi, Mendelssohn, Montaigne, Sanches, Sextus Empiricus, Skeptics

John F. Post (J.F.P.), *Vanderbilt University:* naturalism

Carl J. Posy (C.J.P.), *Duke University:* choice sequence, mathematical intuitionism, philosophy of mathematics

William J. Prior (W.J.P.), *Santa Clara University: ananke*, divided line, *physis*, ring of Gyges, ship of Theseus, Socratic irony, *techne*

Richard Purtill (R.P.), *Western Washington University: a fortiori* argument, argument, *consequentia mirabilis*, equipollence, equivalence, Euler diagram, principle of bivalence, principle of contradiction, principle of excluded middle, Venn diagram

Michael Quante (M.Q.), *Westfälische Wilhelms-Universität:* alienation, recognition

Philip L. Quinn (P.L.Q.), *University of Notre Dame:* divine command ethics, double truth, Swinburne, transubstantiation, Trinitarianism

Philip L. Quinn (P.L.Q.), *University of Notre Dame;* and **Charles C. Taliaferro (C.C.T.),** *St. Olaf College:* philosophy of religion

Elizabeth S. Radcliffe (E.S.R.), *College of William and Mary:* Gay, Hutcheson, moral sense theory, sentimentalism, Shaftesbury, Wollaston

Diana Raffman (D.R.), *Ohio State University;* and **Walter Sinnott-Armstrong (W.S.-A.),** *Dartmouth College:* Marcus

Gerard Raulet (G.Ra.), *Groupe de Recherche sur la Culture de Weimar, Paris:* Kleist, Lessing

Stephen L. Read (S.L.R.), *University of St. Andrews:* exponible, many-valued logic, pluralitive logic, relevance logic

Andrews Reath (A.Rea.), *University of California, Riverside:* Herman

Andrew Reisner (A.Rei.), *McGill University:* Broome

Nicholas Rescher (N.R.), *University of Pittsburgh*: idealism

Henry S. Richardson (H.S.R.), *Georgetown University:* Nussbaum

Robert C. Richardson (R.C.R.), *University of Cincinnati:* black box, figure-ground, heuristics, modularity, split brain effects, Zeigarnik effect

Thomas Ricketts (T.R.), *University of Pennsylvania:* Frege

Wayne D. Riggs (W.D.R.), *University of Oklahoma:* Zagzebski

Mark Roberts (M.Ro.), *State University of New York, Stony Brook:* Barthes, signifier

Robert C. Roberts (R.C.Ro.), *Baylor University:* duck-rabbit

Luke Robinson (L.R.), *Southern Methodist University:* Cartwright

Alexander Rosenberg (A.R.), *Duke University:* Coase theorem, philosophy of economics

Gary Rosenkranz (G.R.), *University of North Carolina, Greensboro:* Lowe

Bernice Glatzer Rosenthal (B.G.R.), *Fordham University:* Shestov

Adina L. Roskies (A.L.R.), *Dartmouth College:* neuroethics

William L. Rowe (W.L.R.), *Purdue University:* agent causation, antinomianism, *causa sui*, Clarke, immanence, prime mover, privation, theological naturalism

T.M. Rudavsky (T.M.R.), *Ohio State University:* Abrabanel, Isaac; Abrabanel, Judah; Crescas

Michael Ruse (M.Ru.), *University of Guelph:* creationism, evolutionary epistemology, social biology

Bruce Russell (B.R.), *Wayne State University:* definist, duty, egoism, good-making characteristic, intuition, normativity, philosophical method, self-evidence

Lilly-Marlene Russow (L.-M.R.), *Purdue University:* imagination

Dan Ryder (D.Ry.), *University of British Columbia:* Millikan

R.M. Sainsbury (R.M.S.), *University of Texas, Austin:* sorites paradox, unexpected examination paradox, Zeno's paradoxes

Joseph Salerno (J.S.), *St. Louis University:* epistemic, epistemic possibility, sleeping beauty problem

Nathan Salmon (N.S.), *University of California, Santa Barbara:* Kripke

Wesley C. Salmon (W.C.S.), *University of Pittsburgh:* confirmation, problem of induction, Reichenbach, theoretical term

Constantine Sandis (C.Sa.), *Oxford Brookes University:* Dancy

David H. Sanford (D.H.S.), *Duke University:* circular reasoning; determinable; implication; indiscernibility of identicals; inference; Johnson, William

Marco Santambrogio (M.Sa.), *University of Cagliari:* Eco

David Sapire (D.S.), *University of the Witwatersrand:* disposition, propensity, state

Ruth A. Saunders (R.A.Sa.), *Wayne State University:* Piaget

Geoffrey Sayre-McCord (G.S.-M.), *University of North Carolina, Chapel Hill:* fact-value distinction

Charles Sayward (C.S.), *University of Nebraska, Lincoln:* conventionalism, deduction, diagonal procedure, formal semantics, open formula, propositional function, quantification

James P. Scanlan (J.P.Sc.), *Ohio State University:* Lenin, Plekhanov

Richard Schacht (R.Sc.), *University of Illinois, Urbana-Champaign:* Nietzsche, philosophical anthropology

Tamar Schapiro (T.Sch.), *Stanford University:* Darwall

Frederick F. Schmitt (F.F.S.), *University of Illinois, Urbana-Champaign*: Goldman

Jerome B. Schneewind (J.B.S.), *Johns Hopkins University:* classical republicanism, Crusius, Cumberland, du Vair, Filmer, Godwin, Grotius, human nature, natural law, Prichard, Pufendorf, Scottish common sense philosophy, Sidgwick, Stephen

Calvin O. Schrag (C.O.S.), *Purdue University:* pluralism, praxis, speculative philosophy

Alan D. Schrift (A.D.S.), *Grinnell College:* Deleuze, Lyotard, poststructuralism

George F. Schumm (G.F.S.), *Ohio State University:* Boolean algebra, completeness, conditional proof, conjunction elimination, conjunction introduction, De Morgan's laws, dilemma, disjunction elimination, disjunction introduction, distributive laws, double negation, existential import, exportation, formal logic, Hintikka set, logical constant, logistic system, meaning postulate, *modus ponens*, *modus tollens*, paraconsistency, Peirce's law, *reductio ad absurdum*, relational logic, singular term, soundness, transformation rule, universal instantiation, valid, well-formed formula, Appendix of Special Symbols

Jean-Loup Seban (J.-L.S.), *Faculté Universitaire de Théologie Protestante de Bruxelles:* Brunschvicg, Cournot, Couturat, d'Ailly, d'Alembert, de Maistre, d'Holbach, Diderot, *Encyclopedia*, Fontenelle, Huygens, Jansenism, Laffitte, La Mettrie, La Peyrère, Luther, Saint-Simon, Swedenborgianism, synergism, Troeltsch, Valentinianism, Vauvenargues

David N. Sedley (D.N.S.), *Christ's College, University of Cambridge:* Epicureanism, Hellenistic philosophy, Stoicism

Kenneth Seeskin (K.See.), *Northwestern University:* Buber, Rosenzweig

Krister Segerberg (K.Seg.), *University of Uppsala:* dynamic logic

Charlene Haddock Seigfried (C.H.S.), *Purdue University:* Paine, pragmatism

Dennis M. Senchuk (D.M.S.), *Indiana University:* philosophy of education

James F. Sennett (J.F.S.), *McNeese State University:* Plantinga

William Lad Sessions (W.L.S.), *Washington and Lee University:* Tillich

Stewart Shapiro (S.Sha.), *Ohio State University:* effective procedure, mathematical structuralism, second-order logic

Tommie Shelby (T.Sh.), *Harvard University:* Appiah

Donald W. Sherburne (D.W.S.), *Vanderbilt University:* Whitehead

Christopher Shields (C.Sh.), *University of Notre Dame:* Irwin

Roger A. Shiner (R.A.Sh.), *University of Alberta:* Dworkin, jury nullification, legal realism, philosophy of law, responsibility

Sydney Shoemaker (S.Sho.), *Cornell University:* Malcolm, personal identity, physicalism, qualia, spatiotemporal continuity

Robert K. Shope (R.K.S.), *University of Massachusetts, Boston:* Lewis, C. I.

Kwong-loi Shun (K.-l.S.), *University of California, Berkeley:* Confucianism; Confucius; Four Books; Gaozi; *gewu zhizhi;* Hanfeizi; *li*^{3}; Mozi; *ren; wu wei; xing; yi; yung; zhi*^{2}*; zhong, shu;* Zhuangzi

Wilfried Sieg (W.S.), *Carnegie Mellon University:* Church's thesis, consistency, formalization, proof theory

A. John Simmons (A.J.S.), *University of Virginia:* authority

Robert L. Simon (R.L.S.), *Hamilton College:* philosophy of sport

Marcus G. Singer (M.G.S.), *University of Wisconsin, Madison:* moral epistemology, polarity, universalizability

Georgette Sinkler (G.S.), *University of Illinois, Chicago:* Bacon, Roger; Gregory of Rimini; Grosseteste; John of Salisbury

Walter Sinnott-Armstrong (W.S.-A.), *Duke University:* experimental philosophy, impartiality, moral dilemma, moral skepticism

Matti T. Sintonen (M.T.S.), *University of Helsinki:* Hintikka

Lawrence Sklar (L.S.), *University of Michigan:* philosophy of science

Brian Skyrms (B.Sk.), *University of California, Irvine:* induction, inductivism, mathematical induction, maximin strategy

Robert C. Sleigh (R.C.Sl.), *University of Massachusetts, Amherst:* Leibniz

Michael Anthony Slote (M.A.Sl.), *University of Maryland, College Park:* satisfice

Hans Sluga (H.S.), *University of California, Berkeley:* Wittgenstein

Barry Smith (B.Sm.), *State University of New York, Buffalo:* Ingarden

Michael Smith (M.Sm.), *Australian National University:* direction of fit, moral rationalism

Robin Smith (R.Sm.), *Texas A&M University:* dialectic

Robert Sokolowski (R.So.), *The Catholic University of America:* Husserl

Robert C. Solomon (R.C.So.), *University of Texas, Austin:* Camus, Sartre

Marta Soniewicka (M.So.), *Jagiellonian University:* global justice, norm, philosophy of medicine, quality of life

Philip Soper (P.S.), *University of Michigan:* civil disobedience, jurisprudence, legal moralism, legal positivism, rule of law

Ernest Sosa (E.S.), *Rutgers University:* Chisholm, condition, justification, Rescher, skepticism, state of affairs

Nicholas Southwood (N.So.), *Australian National University:* Pettit

Paul Vincent Spade (P.V.S.), *Indiana University: complexe significabile, genus generalissimum*, Heytesbury, Kilvington, *praedicamenta*, predicables, *proprietates terminorum, proprium, secundum quid, suppositio*, syncategoremata

T.L.S. Sprigge (T.L.S.S.), *University of Edinburgh:* ethical objectivism, panpsychism

Eric O. Springsted (E.O.S.), *Illinois College:* Weil

George J. Stack (G.J.S.), *State University of New York, Brockport:* Avenarius; Beneke; Czolbe; Hartmann, E. von; Lange; Spir; Steiner; Stirner; Teichmüller

Rebecca Stangl (R.S.), *University of Virginia:* particularism, thick concept, trolley problem

Jason Stanley (J.Sta.), *Yale University:* Chomsky, Stalnaker

Florian Steinberger (F.St.), *Ludwig Maximilian University:* adverbs; bootstrapping; dialetheism; explosion; harmony, proof-theoretic; Lockean thesis; logical pluralism; normalization theorem; Post-Gödel dilemma; preface paradox; principal principle; probabilism; proof; radical interpretation; regulative-constitutive distinction; slingshot argument; substructural logics

Sören Stenlund (S.St.), *Uppsala University:* combinatory logic

Christopher Stephens (C.St.), *University of British Columbia:* Sober

James P. Sterba (J.P.St.), *University of Notre Dame:* ideology, political philosophy

Josef Stern (J.Ste.), *University of Chicago:* Gersonides, Philo Judaeus

Matthias Steup (M.St.), *Purdue University:* Clifford, diallelon, epistemic deontologism, epistemic responsibilism, phenomenal conservatism, problem of the criterion

M.A. Stewart (M.A.St.), *University of Lancaster:* Fordyce, Ray, Stillingfleet, Turnbull

Leopold Stubenberg (L.St.), *University of Notre Dame:* Lehrer

Edith Dudley Sulla (E.D.S.), *North Carolina State University:* Oxford Calculators

Frederick Suppe (F.S.), *University of Maryland, College Park:* abduction, eduction, modality, operationalism

Jere Paul Surber (J.P.Su.), *University of Denver: Erfahrung*, Feuerbach, Herder, Humboldt, Krause, *Lebensphilosophie*, Lotze

David George Sussman (D.G.S.), *University of Illinois:* Korsgaard

Sigrún Svavarsdóttir (S.S.), *Tufts University:* Railton

Zeno G. Swijtink (Z.G.S.), *Indiana University:* Beth's definability theorem, categorical theory, Craig's interpolation theorem, model theory, satisfiable, standard model

Richard Swinburne (R.Sw.), *Oriel College, University of Oxford:* miracle

Charles C. Taliaferro (C.C.T.), *St. Olaf College:* apophatic, deity, evil, Hick, Kenny, kerygma, theological anthropology

Robert B. Talisse (R.B.T.), *Vanderbilt University:* deliberative democracy, establishment, ethics of citizenship, free exercise, neutrality

John Tasioulas (J.Ta.), *University College London:* mercy

Paul Teller (P.Te.), *University of California, Davis:* field theory, reduction

Larry S. Temkin (L.S.T.), *Rutgers University:* equality, ideal, Parfit, transitivity

Mark Textor (M.Te.), *King's College London:* Austrian philosophy

H.S. Thayer (H.S.T.), *City University of New York:* Newton

Peter Thielke (P.T.), *Pomona College:* Allison

Alan Thomas (A.T.), *University of Kent at Canterbury:* Williams

Amie L. Thomasson (A.L.T.), *University of Miami:* ontology of art

Katherine Thomson-Jones (K.T.-J.), *Oberlin College:* philosophy of film

PREFACE TO THE FIRST EDITION

Philosophy has always done extraordinary things with ordinary terms – ‘believe’ and ‘know’, ‘cause’ and ‘explain’, ‘space’ and ‘time’, ‘justice’ and ‘goodness’, ‘language’ and ‘meaning’, ‘truth’ and ‘beauty’, ‘art’, ‘religion’, ‘science’, ‘mind’, ‘perception’, ‘reason’, and countless others. The field has numerous technical terms that are also difficult to define, but it presents a dictionary maker with an even greater challenge because of what it does with our everyday vocabulary. I mean not only the kinds of common words just listed but many perhaps humbler-sounding terms like ‘accident’, ‘action’, ‘grammar’, ‘set’, and ‘vague’. All of the everyday terms characterized in this volume are defined – in some manner – in standard dictionaries of the English language or covered in one or another encyclopedia. But many readers of philosophy – especially lay readers and those in other fields – need something quite different from both, a reference work much more specialized than the former and much less voluminous than the latter. However large they may be, ordinary dictionaries, even when accurate, are insufficiently informative to help readers who must look up terms for philosophical reasons; and, even when philosophically illuminating, encyclopedias and specialized reference books are often too lengthy, and sometimes too diffuse, to give readers a concise statement of what is philosophically central in the use of a term. This dictionary responds to the need for a comprehensive, multi-author philosophical reference work that is at once enormously wide in scope, intermediate in size, and authoritative in content. In far less space than is needed for comparable entries in an encyclopedia of philosophy or in a handbook devoted to a single subfield, this volume treats the multitude of subjects appropriate to a dictionary of philosophy with some of the depth made possible by specialist authors. It does this, so far as possible, in a way that makes many of its entries interesting reading for people simply curious about the intriguing concepts or the profound thinkers of the field.

In the first half of this century, the major philosophical dictionary published in English was James Mark Baldwin’s *Dictionary of Philosophy and Psychology*, a multi-author work published by Peter Smith of Gloucester, Massachusetts; it appeared in 1901 in two volumes (followed by a bibliography in 1905) and was reprinted with revisions in 1925. In the second half of the century, dictionaries of philosophy in English have been much smaller than Baldwin’s and either written by a single author or, occasionally, prepared by a group of writers rarely much larger than a dozen working within the confines of a small space. Few of the entries in these books are longer than 500 words; the most typical have been sketches of 150 words or less.

This dictionary, by contrast, is the work of an international team that includes 381 carefully selected contributors representing the major subfields of philosophy and many philosophical traditions. It contains substantial treatments of major philosophers, many of these entries running to several thousand words. It has hundreds of entries, often of 500 to 1,000 words, on other significant thinkers, and thousands of brief definitions of philosophically important terms. In addition, it provides detailed overviews, some more than 6,000 words, of the subfields of philosophy, such as epistemology, ethics, metaphysics, philosophy of mind, and philosophy of science. It supplies numerous cross-references to help readers in comprehending philosophical ideas, in understanding the terminology of the discipline, and in appreciating philosophers themselves. There are hundreds of entries on important terms and thinkers from non-Western philosophy, for instance from the Chinese, Indian, Japanese, and Korean traditions. The dictionary also covers a number of philosophically significant thinkers and terms from fields closely related to philosophy, including computer science, economics, law, linguistics, literature, mathematics, psychology and other behavioral sciences, and religion. The Appendix defines logical symbols and identifies other special symbols used in philosophy.

In an era that is producing a plethora of encyclopedias, companions, handbooks, and similar reference works, something more should be said about the need for a philosophical dictionary. These kinds of reference works differ significantly: a dictionary is definitional, though like this one it may be far more than that; encyclopedias, companions, and similar works sometimes do not define the terms that head their entries, and the main purposes of these works tend to be informational, historical, and bibliographical. There is no sharp distinction here; a definition may be informative, and the right kind of information about a topic can serve to define the concept in question. But in practice a good definition captures what is conceptually central to its target subject in a way that an encyclopedia or handbook article often does not (and need not) do at all, and quite commonly does not do in any brief, initial formulation.

A purist might think that a dictionary should exclude entries on thinkers altogether, on the ground that proper names do not admit of definition. Even if, strictly speaking, this should be true, it is perfectly intelligible to ask what Socrates, for instance, means to philosophers, or who he was, philosophically speaking. Such questions about thinkers are among the kinds appropriately treated in a philosophical dictionary and likely to interest general readers as well as many in the field of philosophy. Answering them does not require bibliography or extensive biography, and to include either of these would have meant a much longer and quite different volume. Primary texts are often cited in entries that focus on philosophers; but those entries are mainly devoted to central ideas of the thinkers in question. As compared, however, with the other, much smaller contemporary philosophical dictionaries in English, this one has more depth, particularly in entries on major philosophers, on subfields of philosophy, and on pivotal philosophical concepts.

Although the scope of this volume extends beyond Western philosophy and indeed beyond philosophy narrowly conceived, the central focus is on Western philosophers and Western thought. We have sought comprehensiveness, but make no pretense of completeness. Even with entries and subentries covering more than 4,000 concepts and philosophers, we could not include every philosophically significant term, or every thinker, that people interested in philosophy or reading philosophical literature might want to look up. This applies particularly to the areas where philosophy overlaps other fields, such as cognitive science, economic theory, feminist studies, linguistics, literary theory, mathematics, philosophy, and religion. We have, however, sought to include enough entries to assist readers both in approaching a great variety of "purely" philosophical texts and in comprehending a substantial range of interdisciplinary philosophical works.

To avoid distraction and interruptions of the text, internal cross-references (the "See also" ones) are supplied only at the ends of entries. The external cross-references (the "See" ones) are alphabetized along with the main entries and refer the reader to one or more entries that deal with the term or thinker in question. Internal cross-references are not generally used where it seems obvious what sorts of other entries might be consulted for supplementary or related information. The number of internal cross-references has also been kept small. This is in part to avoid diffusing the reader's efforts and in part because the Dictionary has entries that cover most of the philosophers discussed in the text and the vast majority of the philosophical terms the contributors use in their entries. Pursuing the cross-references that are supplied, however, will often lead to other useful ones and to a better understanding of the topic a reader originally looks up.

Many philosophers still living when the Dictionary went to press are cited in the Index of Names, which lists, for each name cited, one or more entries providing information about the person in question. The names included represent more than 600 philosophers and thinkers from all periods of philosophy who are not subjects of entries devoted entirely to their work. There are several reasons why the Dictionary does not contain entries focusing entirely on living figures. Above all, many who would have such entries, including most of the senior philosophers cited in the Index, are still producing philosophical work, and it should not be presumed that adequate portraits of them can be done at this time. The task of writing a description that is both sufficiently short for a volume like this and intellectually adequate is often impossible without a measure of historical distance. In many cases, readers will find helpful information through the Index, which lists hundreds of contemporary philosophers and many other thinkers (though by no means all of the numerous personal names mentioned in the main entries). There are, of course, many important figures in the field whom contributors unfortunately could not bring into the tight confines of their entries.

Some readers might be surprised to find that there is no entry simply on philosophy itself. This is partly because no short definition is adequate. It will not do to define 'philosophy' in the etymological way many have, as 'the love of wisdom': granting that it is natural for philosophers to love wisdom and for many lovers of wisdom to be inspired to pursue philosophy, a lover of wisdom can be quite unphilosophical, and even a good philosopher can be wise in at most a few domains of inquiry. Perhaps a great many philosophers (though certainly not all of them) would agree that philosophy is roughly the critical, normally systematic, study of an unlimited range of ideas and issues; but this characterization says nothing about what sorts of ideas and issues are central in philosophy or about its distinctive methods of studying them. In a way, this dictionary as a whole presents a conception of philosophy, one that is rich in content and widely representative of what has been, is, and perhaps will long continue to be, generally viewed as philosophical work. Those wanting a sense of what a good definition of 'philosophy' must encompass might fruitfully consider how one can define the concerns central to a number of major philosophers representing different periods, styles of philosophy, and cultures. One such list might include Plato, Aristotle, Aquinas, Descartes, Hume, Kant, Hegel, Mill, Peirce, Heidegger, and Wittgenstein. We might also try to construct a unifying characterization of some of the basic fields of philosophy – for instance epistemology, ethics, logic, and metaphysics – and beyond this, one should also consider what is central in such subfields as aesthetics, philosophy of history, philosophy of language, philosophy of logic, philosophy of mind, philosophy of religion, and philosophy of science. Reading the entries on these philosophers and fields will probably yield a much better indication of what philosophy is than we could expect from even a thousand-word entry.

Three features of the text may, for some readers, need comment. First, following a practice common among careful philosophical writers, we place single quotation marks around words or longer expressions when those expressions are named or directly referred to, as where one says that the term 'argument' may designate either the process of arguing or an argument presented therein. The second point concerns terms beginning with 'non', such as 'non-mental'. Except where such terms have a well-established use as words whose meaning is, like that of 'nonviolence' and 'noncombatant', not merely that of the negation of their basic, positive element, our practice is to place a hyphen after 'non'. An example should bring out the difference. Anything at all that is *not* a combatant – anything from ships and shoes and sealing wax to hills, brooks, standing lakes, and groves – is a *non*-combatant, but these things are not thereby noncombatants. Thus, 'noncombatant', 'nonviolence', 'nonstarter', and 'noncognitivism' appear as just written, whereas 'non-mental' and 'non-inferential' are hyphenated. This practice reflects a natural tendency of most philosophers and may be grounded partly in the sense that when used to form a complementary term, 'non' plays a special and very important role: more that of an operator on an established term than the role of a prefix creating a semantically distinctive term. The third point here concerns the substitution of an everyday word for a term often used by philosophers in a technical way. Both for brevity and to aid readers not familiar with the technical use of 'just in case', we have frequently used 'provided' instead of 'just in case' where the latter is equivalent to 'if and only if'. This substitution might have gone unnoticed by anyone other than the contributors affected by it, and no one consulted on the matter has judged that the substitution alters content; but I mention the change just in case anyone should be curious about it.

It is probably impossible to produce a work of this kind without errors, especially errors of omission. Comprehensiveness, of course, does not require completeness (supposing there is a clear notion of completeness for a work like this); nor is completeness even possible in a dictionary covering a dynamic and growing field. I would be happy to receive comments or corrections and will undertake to send them to the appropriate contributor(s) and to file them for possible future use. Two further comments may be in order here. First, although the length of the entries is not unrelated to the importance of their topics, other factors, such as the complexity of the concept in question, the degree of current or recent interest in it, and the style and wishes of the contributors, have also figured in determining length. Second, although authors were asked to strive for the highest level of accessibility appropriate to their topics, some entries are not intended to be fully intelligible to every reader (and, if they were, would ill serve those who need them). We trust that all of the entries have something of value for any interested reader; but some are intended to give specialized or technical information, and others proceed to specialized or technical matters shortly after an opening that is meant to provide what is likely to be essential for any reader consulting the entry.

ACKNOWLEDGMENTS TO THE FIRST EDITION

Special thanks are due to the Board of Advisors, who played a major part in determining the selection of entries. A number of them carefully studied long preliminary entry lists I sent them and also reviewed sample drafts of entries. For work far beyond the call of duty, I would particularly like to thank William P. Alston, Arthur W. Burks, Roderick M. Chisholm, Daniel Garber, Terence Irwin, Norman Kretzmann, John Lucas, John Perry, and Allen Wood, all of whom repeatedly provided comments and advice. I am also grateful for substantial help, during at least one stage, from the late Hector Neri Castañeda and from Fred Dretske, Sally McConnell-Ginet, Michael Moore, Onora O'Neill, Richard Rorty, and Raimo Tuomela.

If there is any single person who stands out as a judicious, steady, and pervasive influence in the development of this dictionary, it is Terence Moore, Executive Editor at Cambridge University Press. He persuaded me to undertake the work of Editor-in-Chief in the first place, helped in the development of the volume at each formative stage, and provided editorial advice in every major phase. With a sharp critical eye, he attended to fine points of style and organization; he proposed authors, topics, and procedures; and he guided the design of both the text and its cover.

Many of the contributors provided indispensable advice along the way, and I am deeply grateful for their help. A large number of them revised their entries in the light of editorial comments, sometimes more than once. Many also spontaneously sent me updated versions or improvements during the years of the project. For my part, philosophical discussions with the contributors and the Editorial Board were a sustaining factor in a long and arduous task. These years of intensive work with a cross section of the world's best philosophers have given me a strong sense of the vitality and intellectual power of the profession of philosophy. I believe that a commitment to scholarship and truth prevails over fashion and idiosyncrasy and polemics.

The Dictionary has benefited from the advice of a number of experts in subfields of philosophy. Michael Detlefsen, drawing on his own long editorial experience in the field of logic, and George Schumm, who produced the Appendix of Special Symbols, were immensely helpful in determining and preparing a good portion of the hundreds of entries in logic and philosophy of mathematics. Kwong-loi Shun gave me advice at several points on the Chinese philosophy entries. Keith Yandell played a similar advisory role for the entries concerning Buddhism and Hinduism. Alexander Mourelatos provided excellent advice on some of the Greek philosophy entries. Comments and advice were also contributed by more people than I can name. They include James Allard, David Allison, Kent Bach, Lawrence Becker,

Joseph Bien, Daniel Breazeale, Robert Butts, Victor Caston, James Childress, Wayne Davis, John Dillon, John Etchemendy, Bernard Gert, Lenn Goodman, Jorge Gracia, James Gustafson, Gary Gutting, John Heil, Robert Kane, George Kline, Joseph Kockelmans, Manfred Kuehn, Steven Kuhn, William McBride, William Mann, A. P. Martinich, Alfred Mele, Paul Moser, Donald Munro, Paul Pines, Louis Pojman, Carl Posy, William Rowe, Wesley Salmon, Richard Schacht, Jerome Schneewind, Calvin Schrag, Jean-Loup Seban, Hans Seigfried, Sydney Shoemaker, Ernest Sosa, M. A. Stewart, Elenore Stump, Paul Walker, Stephen White, Rega Wood, and, especially, Hugh McCann.

Technical and editorial assistance was provided by a number of people. W. M. Havighurst single-handedly did the copyediting for the Press and, with a keen eye and a deft hand, markedly improved the text at many points. His work required verifying large quantities of information, tracking thousands of details, and maintaining constant communication with me over nearly a year. Together we have tried to preserve both the contributors' content and, so far as possible in a volume of this kind, their style. I am also especially grateful to Allison Nespor for extensive help with the Index of Names, for proofreading of the entire volume, and for editorial advice at many points throughout the years of the project. I should add that the production schedule did not permit every contributor to read proofs, and some who read proofs did not read them for every entry they wrote. Errors that may have slipped through the several proofreadings may not be the responsibility of the contributors.

At the Press, I have received help and advice from Michael Agnes, Alan Gold, Kenneth Greenhall, Cathy Hennessy, Christine Murray, Alexis Ruda, and, especially, Sophia Prybylski, who painstakingly oversaw the entire process of correcting the proofs. My assistants in the Department of Philosophy at the University of Nebraska, Lincoln, have also been of help: Priscella Guerra, Nancy Slonneger, Michael Tonderum, Douglas Weber, and Xiaomei Yang. The support of the University of Nebraska and, especially, of my colleagues in the Philosophy Department, has been indispensable. I am also grateful for assistance from the Philosophy Department at Santa Clara University during my term as Fagothey Distinguished Professor in 1994.

I owe an incalculable debt to my family. Over the seven years of this project, my wife, Marie-Louise, gave me both advice on textual and literary matters and help with organization of files and some of the many mailings to authors. She and my children, Katherine, Evelyn, and Paul, also assisted with myriad editorial and clerical tasks and cheerfully tolerated the interruptions and problems that are inevitable in producing a work of this magnitude.

Robert Audi
Lincoln, Nebraska
February 1995

PREFACE TO THE SECOND EDITION

The widespread positive reception of the First Edition has been gratifying, and a number of translations are proceeding, into Chinese, Italian, Korean, Russian, and Spanish at this writing. The field of philosophy has expanded, however, and even apart from that I have become aware of several respects in which the Dictionary can better serve its readers. The result is a multitude of expansions in standing entries and the addition of some four hundred new entries. This extended coverage required sixty new authors, nearly half of them from outside North America.

The new entries range across the entire field of philosophy. We have made a special effort to increase our coverage of Continental philosophy and of subfields where growth is exceptionally rapid, such as ethics, philosophy of mind, and political philosophy. We have also added numerous cross-references. The cross-references are an element in the volume that many readers have said they found not only valuable in enhancing their initial understanding of an entry, but also welcome as a source of intriguing connections and as an invitation to browse.

In addition to citations of many living philosophers in the Index of Names, there is now selective coverage of a number of living philosophers in separate entries. With very few exceptions, this (quite small) group includes only thinkers in their mid-sixties or older. This constraint on inclusion is in part dictated by the difficulty of providing an adequate portrait of philosophers still actively advancing their positions, and it has required omitting a number of distinguished younger philosophers still making major changes in their views. Even with much older thinkers we do not presuppose that there will be no significant developments, but only a greater likelihood of discerning a rounded position that is unlikely to be abandoned.

In the difficult – and in a sense impossible – task of determining entries on living thinkers, advice was sought from both the Board and many other sources. We were also guided in part by the extent to which contributors to the First Edition relied on references to certain living thinkers. Given the Dictionary's overall purposes and its wide audience, which includes many readers outside philosophy, selection was weighted toward writers whom many *non-philosophers* may want to look up, and some weight was also given to considerations of diversity. In keeping with the overall purposes of the volume and the diversity of its readers, we have also decided not to undertake the large task of covering either living contributors to highly specialized subfields – such as logic or computer theory or much of philosophy of science – or philosophers whose main contributions are to the history of philosophy. There are, however, many important philosophers in these fields. A number are cited in the Index, which also lists many of the thinkers who are mentioned by one or more contributors but are not subjects of separate entries.

In taking account of the responses from readers of the First Edition, we have tried to do as much as possible without making the Dictionary too bulky for a single volume. So much of the response has been positive that although many standing entries have been revised, we have sought to make improvements in the book mainly by adding new ones. A few readers expressed puzzlement or disappointment that we do not have a bibliography at the end of each entry. We do generally have references to primary works by the thinker being portrayed or, in some cases, secondary works noteworthy in their own right. Our policy here is shaped partly by severe space constraints and, especially given those, by a desire to avoid directing readers to inadequately representative sources or works that may soon become obsolete. It is also based on a sense of the difference between a dictionary and an encyclopedia. Granting that this difference is not sharp, a dictionary is above all definitional, whereas encyclopedias are mainly informational, historical, and bibliographical. A dictionary clarifies basic concepts in a way encyclopedias need not. Indeed, some encyclopedias are best understood with the help of a good dictionary; some are even difficult to read without one.

As with the First Edition, I would be happy to receive comments or corrections and will undertake to file them and to send them to the appropriate author(s). Many of the Dictionary's contributors, as well as a number of careful readers, sent suggested corrections, and most of the suggestions have been followed or taken into account in preparing this edition. I should reiterate that, again as with the First Edition, these years of intensive work with a cross section of the world's best philosophers have given me a strong sense that the profession of philosophy has great vitality and intellectual strength. In both contributors and advisors, I have seen a steadfast commitment to scholarship, an abiding concern with accuracy and theoretical depth, an abundance of philosophical imagination, and a fidelity to high standards that prevails over the often alluring currents of schools or fashions or polemics. It is perhaps not appropriate for me to dedicate a collaborative volume of this kind, but if I were to do so, I would dedicate it to the contributors, in the hope that it may give to them and to all its readers some of the pleasure that the editing has given to me.

ACKNOWLEDGMENTS TO THE SECOND EDITION

In constructing this volume over a number of years, I have benefited from more comments and reactions than I can possibly remember, and I regret any omissions in the expressions of gratitude that follow.

The Board of Advisors deserves hearty thanks for a major part in the selection of new entries and new contributors. I would particularly like to thank William P. Alston, Arthur W. Burks, Fred Dretske, Terence Irwin, the late Norman Kretzmann, John Lucas, Sally McConnell-Ginet, Alexander Nehamas, Onora O'Neill, John Perry, Richard Rorty, John Searle, Raimo Tuomela, and Bas van Fraassen, many of whom repeatedly provided comments or advice. The editorial advice of Terence Moore, Executive Editor at the Press, and my regular discussions with him on matters of policy and design, have been incalculably valuable. Neither edition would have been possible without his contributions.

The Second Edition has benefited from the advice of many others, including a number who helped in preparing the First Edition. Among these are John Corcoran, Gary Gutting, George Schumm, Kwong-loi Shun, and Keith Yandell,

all of whom provided editorial advice and recommended adding certain entries in their areas of philosophical work or revising others. Corcoran deserves a great deal of credit for both identifying and filling gaps. Comments and advice were also contributed by more people than I can name. They include Margaret Atherton, Claudio de Almeida, Lynne Rudder Baker, Joseph Bien, Noël Carroll, Roger Crisp, Wayne Davis, Philip Gasper, Berys Gaut, Lenn Goodman, Paul Griffiths, Oscar Haac, Mike Harnish, John Heil, Brad Hooker, Patricia Huntington, Dale Jacquette, Robert Kane, George Kline, Manfred Kuehn, Steven Kuhn, William Mann, Ausonio Marras, Al Martinich, Brian McLaughlin, Alfred Mele, Joseph Mendola, David W. Miller, Paul Moser, James Murphy, Louis Pojman, William Prior, Mark Sainsbury, Wesley Salmon, Charles Sayward, Jerome Schneewind, Calvin Schrag, David Sedley, Roger Shiner, Marcus Singer, Brian Skyrms, M. A. Stewart, William Wainwright, Paul Weirich, and, especially, Hugh McCann, Ernest Sosa, and J. D. Trout.

Conscientious reviewers as well as colleagues and readers who contributed comments have been of help to me in expanding and revising the First Edition. Among the readers – mainly philosophers – I particularly want to thank Alasdair MacIntrye, Ruth Marcus, Dan Mueller, Eleonore Stump, and Mark van Roojen.

Editorial and technical assistance was provided by a number of people. At the Press, I have received help or advice from Michael Agnes, Janis Bolster – who oversaw the entire process of correcting the proofs – Alan Gold, Kenneth Greenhall, Cathy Hennessy, Nicholas Mirra, Christine Murray, Gwen Seznec, and others. W. M. Havighurst again served as the main copy editor for the Press; his skillful and painstaking work has been of great help throughout. Allison Nespor and my assistants in the Department of Philosophy at the University of Nebraska, Lincoln, Jonathan Evans and Xiaomei Yang, have also contributed. The support of the University of Nebraska and my colleagues in the Philosophy Department has been indispensable. I am also grateful for assistance from the Philosophy Department at Santa Clara University during my term as Distinguished Professor of the College of Arts and Sciences in 1999.

As in the case of the First Edition, I owe an incalculable debt to my family. My wife, Marie-Louise, gave me both literary advice and help with organization of files and some of the many mailings. She and my children have also cheerfully tolerated the interruptions and problems that are inevitable in doing even a second edition of a work of this scope.

June 1999

PREFACE TO THE THIRD EDITION

This dictionary has proved to be a highly respected and often consulted resource not only for philosophers but for many others. The present edition is built largely on the same editorial conceptions governing the previous two, as described in the prefaces to the earlier editions. This edition differs from the previous two mainly in enhanced coverage. There are hundreds of new basic entries, and several hundred other new entries – often with considerable information – are embedded in basic ones. Most of these embedded entries are quite short, but many are sufficiently detailed to help those in need of a starting place for reflection on the topic. Moreover, the cross-references at the ends of basic entries will help readers to pursue in some detail concepts or thinkers important for their work.

Many of the entries in the Second Edition have been revised (and a very few have been removed). All contributors to the Second Edition who could be reached – the vast majority – were offered a chance to review and, if need be, revise their contributions. A number of contributors thought that no revision was needed; I believe this is indicative of the care with which their entries were composed. In every case where changes were made, the revisions are beneficial. As in the past, however, I am happy to receive suggestions and comments.

The Index of Selected Names includes, as before, most of the proper names not having headword entries but appearing in the text of basic entries. This index has been greatly expanded. It includes many philosophers who, if not for their age or our space constraints (or, in some cases, insufficient information), would have had headword entries. The amount of information provided regarding philosophers cited in the index is highly variable. Fortunately, additional information, even if not in the compressed holistic form we have aimed at here, is readily available on the Internet and in other generally accessible places.

Among the new entries are many that describe leading contemporary philosophers whose work may now be presumed to be sufficiently rounded out to make possible the kind of broad coverage appropriate to a dictionary of philosophy. The rationale for the difficult task of selection is much as it was in the Second Edition (see p. xxxvii for further explanation). One result of our selection procedure is that (with very few exceptions) only philosophers sixty-five or (usually) older are included. This is a largely arbitrary line, though it does correspond to the most common (approximate) retirement age in the field.

One change from the selection practice of the Second Edition is the inclusion of a larger proportion of philosophers commonly considered historians of philosophy. Those selected are also contributors to philosophy in their own right; but this is a good place to add that on the conception of the field guiding this dictionary, the history of philosophy, practiced as a systematic reflective engagement with major figures, is itself part of philosophy as the intellectual quest it is properly taken to be.

Here, as in the selection of entries about living philosophers, my information and advice, carefully sought though they have been, were limited. We can make no claim to an entirely adequate selection even apart from the acknowledgment of a less than fully comprehensive coverage of major contemporary philosophers. It is especially important to add that many contemporary philosophers not subjects of headword entries are informatively referred to in entries on topics to which their work is relevant, and the Index provides reference to hundreds of philosophers not having headword entries.

It should also be stressed that the selection of a contemporary philosopher carries no implication that philosophers in the same age range or field who were not described in headword entries have made lesser contributions. Among the many reasons for emphasizing this are the number of people in question, the difficulty of evaluating their contributions, the existence, often, of important unpublished or even largely unknown contributions, and the editors' concern to give some weight to the inclusion of authors likely to be subjects of inquiry by those using a wide-scope dictionary of this kind. Other things being equal, the more specialized a thinker's work, the less likely inclusion has been; and the wider the probable interest of a philosopher's work among expected readers of this volume, the more likely inclusion has been.

Another new element of this edition is a considerable increase in the number of entries on the philosophy of a single country or a group of countries that have a common language or are otherwise connected in a way that makes broad treatment possible (as with those on Australasian philosophy, Latin American philosophy, Nordic philosophy, and Spanish philosophy). Editorial decisions required weighing the risks of omission and of necessarily incomplete coverage against the benefits of comprehensiveness and a source of integration and historical perspective, a source very difficult to find among short articles. The authors of these entries undertook a very difficult task, but the results should assist at least readers who do not know the philosophical tradition in question – and may in different ways assist some who do.

A few conventions adopted in this dictionary deserve mention. Our practice is to represent philosophy in a way that preserves, within the editorial constraints of definatory emphasis and brevity of expression, the stylistic preferences of the most discriminating philosophical writers. This applies, for instance, to the use of single and double quotation marks, hyphens, italics, and other matters of punctuation and usage. A few points about what brevity has required should be noted here. First, many entries do not have cross-references at their conclusion, often because such references would not help readers or because it is obvious where the Dictionary addresses connected topics. Second, the mention of a philosopher (such as Hume or Kant) in an entry by surname alone on its *first* occurrence indicates that the Dictionary has a headword entry about the person. If it has two or more entries that begin with the same last name, as with James Mill and John Stuart Mill, identifying reference is made. Finally, though we now use mainly the pinyin transliteration for Chinese names and terms, we have retained the Wade-Giles spellings in appropriate places for those who might look up the term or thinker in question using that transliteration, which is still standard in many works about them.

Philosophy is a field in motion, and new terms are appearing perhaps more quickly than ever. Which of these have become established is difficult to determine, and which will remain in use cannot always be foreseen. This limitation accounts for the fact that a number of current philosophical terms do not figure here, at least not in headword entries. Moreover, philosophy has quite properly refused to treat the major works constituting its past as irrelevant, or only tangentially relevant, to its present concerns; and with this in mind we have added entries covering terms, as well as some philosophers, whose significance lies mainly in the history of philosophy. Our hope is that given the continuity between the past and present in philosophy, and given its tendency to grow outward and upward from its past rather than to abandon its history, this dictionary will, for many years to come, be valuable for readers in the field.

ACKNOWLEDGMENTS TO THE THIRD EDITION

A cooperative volume of this kind is impossible without the work of not only the contributors but also many others. I reiterate thanks to the contributors to the preceding edition whose work appears here unchanged, but I particularly want to thank the many who updated one or more of their entries, and I am immensely grateful for the many new entries written for the volume by the more than one hundred new contributors. Among the contributors who were particularly helpful I must specially thank Karl Ameriks, Mario De Caro, Roger Crisp, Wayne Davis, Miranda Fricker, Cody Gilmore, Peter J. Graham, John Heil, Stephen Hetherington, Vittorio Hösle, Ralph Kennedy, the late E. J. Lowe, Brian McLaughlin, Christian Miller, Stephen Morse, Nikolaj Nottelmann, Elizabeth Radcliffe, Alan Schrift, Florian Steinberger, Charles Taliaferro, Robert Tully, and Peter van Inwagen. Many members of the Board of Editorial Advisors also helped in the selection of both new entries and new contributors; and for their advice and ideas I particularly want to thank John Corcoran, Dagfinn Føllesdal, Rainer Forst, Walter Sinnott-Armstrong, Ernest Sosa, Raimo Tuomela, and Peter van Inwagen. Expert advice was also provided by Patricia Blanchette, who reviewed many entries in logic; George Kline, who reviewed those in Russian philosophy; Kwong-loi Shun, who reviewed the entries on Chinese philosophy and provided pinyin equivalents for the great majority of those transliterated following the older, Wade-Giles system; and Anjan Chakravartty.

A volume of this kind requires more contributions from the Press than the Editor ever hears of, but some of its professionals have stood out. Beatrice Rehl, Director of Publishing, Humanities, for the Press, has had a major role in the development of this dictionary ever since its first edition. She has given me sage advice at numerous stages in the preparation of this edition; she has reviewed and discussed many issues needing resolution during the years of preparation; and she also assembled a fine team of other editors to join the project at the production stage. Here I think of Janis Bolster, who skillfully guided and monitored much of the long production process, Shari Chappell, Isabella Vitti, Anastasia Graf, and Mary Becker, who served as an expert copy editor for the entire volume. She had to study, and in places correct, not only all of the new entries but also the thousands of entries reproduced – often imperfectly – from the Second Edition. I appreciate not just her review of the myriad usual elements essential before typesetting, but also her attention to the sense of each sentence. If all her work is, as I shall try to bring about, adequately reflected in the bound book, we shall have achieved a great deal. My assistant at the

University of Notre Dame, Daniel Immerman, was of great help at many points and did detailed work in several early stages of the project. The University itself also supported the project, and I particularly want to thank Deans John McGreevy and Maura Ryan for providing released time during a semester when the demands of the Dictionary were especially heavy.

For work of many kinds I am grateful to Paul Audi, who served as Associate Editor. He read and commented on many drafts, especially those in metaphysics; he advised on policy matters, format, and editorial practice; and he helped in the selection of new entries and new authors and in the preparation of detailed guidelines for their contributions. Despite all that he and the Press's staff have done, however, I must take final responsibility for any avoidable omissions and errors that crept through. As with the earlier editions, I will undertake to collect and, wherever possible, take account of corrections and comments.

THE
CAMBRIDGE DICTIONARY
OF
PHILOSOPHY

THIRD EDITION

A

Abailard, Pierre. See ABELARD.

Abdera, School of. See ABDERITES.

Abderites, the Greek philosophers Leucippus and Democritus, the two earliest exponents of atomism. Even though Abdera, in Thrace (northern Greece), was home to three pre-Socratics – Leucippus, Democritus, and Protagoras – the term 'Abderites' and the phrase 'School of Abdera' are applied only to Leucippus and Democritus. We can thus distinguish between early Greek atomism and Epicureanism, which is the later version of atomism developed by Epicurus of Athens. This modern usage is in one respect inapt: the corresponding Greek term, *Abderitēs, -ai*, was used in antiquity as a synonym of 'simpleton' – not in disparagement of any of the three philosophers of Abdera but as a regional slur.

See also ANCIENT ATOMISM, PRE-SOCRATICS.

A.P.D.M.

abduction, canons of reasoning for the discovery, as opposed to the justification, of scientific hypotheses or theories. Reichenbach distinguished the *context of justification* and the *context of discovery*, arguing that philosophy legitimately is concerned only with the former, which concerns verification and confirmation, whereas the latter is a matter for psychology. Thus he and other logical positivists claimed there are inductive logics of justification but not logics for discovery. Both hypothetico-deductive and Bayesian or other probabilistic inductive logics of justification have been proposed. Close examination of actual scientific practice increasingly reveals justificatory arguments and procedures that call into question the adequacy of such logics.

Norwood Russell Hanson distinguished the reasons for accepting a specific hypothesis from the reasons for suggesting that the correct hypothesis will be of a particular kind. For the latter he attempted to develop logics of *retroductive* or *abductive* reasoning that stressed analogical reasoning, but did not succeed in convincing many that these logics were different in kind from logics of justification. Today few regard the search for rigorous formal logics of discovery as promising. Rather, the search has turned to looking for "logics" in some weaker sense. Heuristic procedures, strategies for discovery, and the like are explored. Others have focused on investigating rationality in the growth of scientific knowledge, say, by exploring conditions under which research traditions or programs are progressive or degenerating. Some have explored recourse to techniques from cognitive science or artificial intelligence. Claims of success generally are controversial.

See also CONFIRMATION, INDUCTION, REICHENBACH.

F.S.

Abelard, Peter, in French, Pierre Abailard or Abélard (1079–1144), French theologian whose writings, particularly *Theologia Christiana*, constitute one of the more impressive attempts of the medieval period to use logical techniques to explicate Christian dogmas. He was born of a minor noble family in Brittany and studied logic and theology under some of the most notable teachers of the early twelfth century, including Roscelin, William of Champeaux, and Anselm of Laon. He rapidly eclipsed his teachers in logic and attracted students from all over Europe. His forays into theology were less enthusiastically received. Twice his views on the Trinity were condemned as heretical. Abelard led a dramatic life punctuated by bitter disputes with his opponents and a dangerous and celebrated love affair with Heloise (c.1117). Much of this story is told in his autobiographical work, *Historia calamitatum*.

Abelard's two most important works in logic are his *Logica ingredientibus* and his *Dialectica*. In these treatises and others he is the first medieval Scholastic to make full use of Aristotle's *On Interpretation* and Boethius's commentaries on it to produce a sophisticated theory of the signification of words and sentences. The theory distinguishes the signification of an expression both from what the expression names and from the idea in the mind of the speaker associated with the expression. Abelard allows a role for mental images in thinking, but he carefully avoids claiming that these are what words signify. In this he is very much aware of the pitfalls of subjectivist theories of meaning. His positive doctrines on what words signify tie in closely with his views on the signification of propositions and universals. For Abelard propositions are sentences that are either true or false; what they say (their *dicta*) is what they signify and these *dicta* are the primary bearers of truth and falsity. Abelard developed a genuinely propositional logic, the first since the Stoics. A universal, on the other hand, is a common noun or adjective, and what it means is what the verb phrase part of a proposition signifies. This is a sort of truncated *dictum*, which Abelard variously called a *status*, nature, or property. Neither *status* nor *dicta* are things, Abelard said, but they are mind-independent objects of thought. Abelard was particularly devastating in his attacks on realist theories of universals, but his view that universals are words was not meant to deny the objectivity of our knowledge of the world.

Abelard's theories in logic and ontology went far beyond the traditional ideas that had been handed down from Aristotle through the mediation of the late ancient commentators, Boethius in particular. They could have formed the basis of a fundamentally new synthesis in Western logic, but when more of the Aristotelian corpus became available in Western Europe during the twelfth century, concentration shifted to assimilating this already fully elaborated system of ideas. Consequently, Abelard's influence on later Scholastic thought, though noticeable, is not nearly as great as one might expect, given the acuteness and originality of his insights.

abhidharma, the analytical and systematic presentation of the major conceptual categories constituting Buddhist doctrine; used as a label for both the texts that contain such presentations and the content of what is presented. Early *abhidharma* texts (up to about the second century A.D.) are catechetical in form, defining key doctrinal terms schematically through question and answer; later works are more discursive, often containing extensive discussions of controverted metaphysical issues such as the existence of past objects or the nature of reference. The goal of *abhidharma* is to make a complete inventory of existents and of the relations that may hold among them. **See also** BUDDHISM. P.J.G.

abhinivesha (Sanskrit, 'self-love' or 'will to live'). In Indian philosophy in general and in the Sankhya-Yoga system in particular, *abhinivesha* was regarded as an aspect of *avidya* (ignorance). Some other manifestations of *avidya* were said to be fear, attachment, and aversion, all of which were thought to generate karmic bondage and prevent one from attaining spiritual liberation. Lumped together with these, *abhinivesha* obviously has a negative connotation, even though in the Indian tradition it was not necessarily wrong, and even commendable at times, to exhibit self-love and a healthy will to live and prosper in the material world. So presumably the negative connotation of *abhinivesha* is an indication that what may be otherwise permissible can be improper or morally wrong if pursued in excess or for the wrong reason. **See also** AVIDYA. abortion. See MORAL STATUS.

Abrabanel, Isaac ben Judah (1437–1508), Spanish Jewish philosopher and statesman. On the periphery between late medieval Spanish philosophy and Renaissance humanism, Abrabanel concerned himself with traditional medieval Jewish subjects such as creation, prophecy, and theodicy. His works include biblical commentaries as well as philosophical and theological treatises; his most significant writings constitute his critique of Maimonides' *Guide of the Perplexed*, found in *Rosh Amanah* (1505) and *Mifalot Elohim* (1503). In criticizing the Aristotelians, Abrabanel was influenced by Isaac Arama. Endorsing the rabbinic concept of prophecy, Abrabanel attacks Maimonides' naturalistic views of prophecy: he argues that Moses is not to be distinguished from the other prophets and that the knowledge of the prophets is not merely scientific and metaphysical, but miraculously produced by God. This emphasis upon the miraculous as opposed to the natural is developed in his theory of history and politics. His views about the ideal state reflect humanist leanings. While Abrabanel does see the civilized state of humans as a rebellion against God resulting from the Fall, he is interested in the best kind of government under these circumstances. Accordingly, unity of society does not require a concentrated power but can be achieved through a collective will. This kind of government, Abrabanel claims, is advocated by the Torah and shown to be effective by the Italian republics of the period. With the coming of the Messiah, humankind will realize its spiritual potential, and when the corporeal universe vanishes, each soul will be able to contemplate eternally the essence of God. Abrabanel's political views influenced later Jewish messianic movements, and his biblical commentaries, translated into Latin, influenced later Christian humanist circles. **See also** ABRABANEL, JUDAH; MAIMONIDES. T.M.R.

Abrabanel, Judah, also called Leone Ebreo or Leo Hebraeus (c.1460–c.1523), Spanish Jewish philosopher, poet, and physician. The oldest son of Isaac Abrabanel, Judah Abrabanel was, philosophically, a representative of Italian Platonism. He wrote his predominantly Neoplatonic philosophical work *Dialoghi d'Amore* ("Dialogues of Love") in 1535. The original Italian manuscript was translated into French, Latin, Spanish, and Hebrew between 1551 and 1560. The interlocutors of this Platonic-style dialogue, Sophia and Philo, explore the nature of cosmic love. This love not only exists between God and creatures, but also operates in matter and form, the four elements, and the entire universe; it reflects both sensuous and intellectual beauty; in short it is transformed from a relation between God and the universe into a fundamental force around which all things are ordered. There is a mystical aspect to Abrabanel's account of love, and it is not surprising that reflections on mysticism, in addition to astrology, astronomy, and aesthetics, emerge throughout the work. Although primarily reflecting medieval Platonism and Neoplatonism, Abrabanel was also influenced by Marcilio Ficino, Pico della Mirandola, Maimonides, and Ibn Gabirol. His dialogue was read by many philosophers, including Giordano Bruno and Spinoza. His concept of love may be found in lyrical poetry of the period in Italy, France, and Spain, as well as in Michelangelo's *Sonnets* and Torquato Tasso's *Minturno*. **See also** ABRABANEL, ISAAC. T.M.R.

absent qualia. See FUNCTIONALISM, PHILOSOPHY OF MIND.

absolute, the, as conceived by idealists, the one independent reality of which all things are an expression. Kant used the adjective (translated as) 'absolute' to characterize what is unconditionally valid. He claimed that pure reason searched for absolute grounds of the understanding that were ideals only, but that practical reason postulated the real existence of such grounds as necessary for morality. This apparent inconsistency led his successors to attempt to systematize his view of reason. To do this, Schelling introduced the term 'the Absolute' for the unconditioned ground (and hence identity) of subject and object. Schelling was criticized by Hegel, who defined the Absolute as spirit: the logical necessity that embodies itself in the world in order to achieve self-knowledge and freedom during the course of history. Many prominent nineteenth-century British and American idealists, including Bosanquet, Royce, and Bradley, defended the existence of a quasi-Hegelian absolute. **See also** HEGEL, IDEALISM, SCHELLING. abstracta. See ABSTRACT ENTITY, NATURALISM.

abstract entity, an object lacking spatiotemporal properties, but supposed to have being, to exist, or (in medieval Scholastic terminology) to subsist. Abstracta, sometimes collected under the category of universals, include mathematical objects, such as numbers, sets, and geometrical figures, propositions, properties, and relations. Abstract entities are said to be abstracted from particulars. The abstract triangle has only the properties common to all triangles, and none peculiar to any particular triangles; it has no definite color, size, or specific type, such as isosceles or scalene. Abstracta are admitted to an ontology by Quine's criterion if they must be supposed to exist (or subsist) in order to make the propositions of an accepted theory true. Properties and relations may be needed to account for resemblances among particulars, such as the redness shared by all red things. Propositions as the abstract contents or meanings of thoughts and expressions of thought are sometimes said to be necessary to explain translation between languages, and other semantic properties and relations.

Historically, abstract entities are associated with Plato's realist ontology of Ideas or Forms. For Plato, these are the abstract and only real entities, instantiated or participated in by spatiotemporal objects in the world of appearance or empirical phenomena. Aristotle denied the independent existence of abstract entities, and redefined a diluted sense of Plato's Forms as the secondary substances that inhere in primary substances or spatiotemporal particulars as the only genuine existents. The dispute persisted in medieval philosophy between realist metaphysicians, including Augustine and Aquinas, who accepted the existence of abstracta, and nominalists, such as Ockham, who maintained that similar objects may simply be referred to by the same name without participating in an abstract form. In modern philosophy, the problem of abstracta has been a point of contention between rationalism, which is generally committed to the existence of abstract entities, and empiricism, which rejects abstracta because they cannot be experienced by the senses. Berkeley and Hume argued against Locke's theory of abstract ideas by observing that introspection shows all ideas to be particular, from which they concluded that we can have no adequate concept of an abstract entity; instead, when we reason about what we call abstracta we are actually thinking about particular ideas delegated by the mind to represent an entire class of resemblant particulars, from which we may freely substitute others if we mistakenly draw conclusions peculiar to the example chosen. Abstract propositions were defended by Bolzano and Frege in the nineteenth century as the meanings of thought in language and logic. Dispute persists about the need for and nature of abstract entities, but many philosophers believe they are indispensable in metaphysics.

Academic Skepticism. See SKEPTICISM, SKEPTICS.

Academy, the school established by Plato around 385 B.C. at his property outside Athens near the public park and gymnasium known by that name. Although it may not have maintained a continuous tradition, the many and varied philosophers of the Academy all considered themselves Plato's successors, and all of them celebrated and studied his work. The school survived in some form until A.D. 529, when it was dissolved, along with the other pagan schools, by the Eastern Roman emperor Justinian I. The history of the Academy is divided by some authorities into that of the Old Academy (Plato, Speusippus, Xenocrates, and their followers) and the New Academy (the Skeptical Academy of the third and second centuries B.C.). Others speak of five phases in its history: Old (as before), Middle (Arcesilaus), New (Carneades), Fourth (Philo of Larisa), and Fifth (Antiochus of Ascalon).

For most of its history the Academy was devoted to elucidating doctrines associated with Plato that were not entirely explicit in the dialogues. These "unwritten doctrines" were apparently passed down to his immediate successors and are known to us mainly through the work of Aristotle: there are two opposed first principles, the One and the Indefinite Dyad (Great and Small); these generate Forms or Ideas (which may be identified with numbers), from which in turn come intermediate mathematicals and, at the lowest level, perceptible things (Aristotle, *Metaphysics* I.6).

After Plato's death in 347, the Academy passed to his nephew Speusippus (c.407–339), who led the school until his death. Although his written works have perished, his views on certain main points, along with some quotations, were recorded by surviving authors. Under the influence of late Pythagoreans, Speusippus anticipated Plotinus by holding that the One transcends being, goodness, and even Intellect, and that the Dyad (which he identifies with matter) is the cause of all beings. To explain the gradations of beings, he posited gradations of matter, and this gave rise to Aristotle's charge that Speusippus saw the universe as a series of disjointed episodes. Speusippus abandoned the theory of Forms as ideal numbers, and gave heavier emphasis than other Platonists to the mathematicals.

Xenocrates (396–314), who once went with Plato to Sicily, succeeded Speusippus and led the Academy until his own death. Although he was a prolific author, Xenocrates' works have not survived, and he is known only through the work of other authors. He was induced by Aristotle's objections to reject Speusippus's views on some points, and he developed theories that were a major influence on Middle Platonism, as well as on Stoicism. In Xenocrates' theory the One is Intellect, and the Forms are ideas in the mind of this divine principle; the One is not transcendent, but it resides in an intellectual space above the heavens. While the One is good, the Dyad is evil, and the sublunary world is identified with Hades. Having taken Forms to be mathematical entities, he had no use for intermediate mathematicals. Forms he defined further as paradigmatic causes of regular natural phenomena, and soul as self-moving number.

Polemon (c.350–267) led the Academy from 314 to 267, and was chiefly known for his fine character, which set an example of self-control for his students. The Stoics probably derived their concept of *oikeiosis* (an accommodation to nature) from his teaching. After Polemon's death, his colleague Crates led the Academy until the accession of Arcesilaus.

The New Academy arose when Arcesilaus became the leader of the school in about 265 B.C. and turned the dialectical tradition of Plato to the Skeptical aim of suspending belief. The debate between the New Academy and Stoicism dominated philosophical discussion for the next century and a half. On the Academic side the most prominent spokesman was Carneades (c.213–129 B.C.).

In the early years of the first century B.C., Philo of Larisa attempted to reconcile the Old and the New Academy. His pupil, the former Skeptic Antiochus of Ascalon, was enraged by this and broke away to refound the Old Academy in about 87 B.C. This was the beginning of Middle Platonism (c.80 B.C.–A.D. 220). Antiochus's school was eclectic in combining elements of Platonism, Stoicism, and Aristotelian philosophy, and is known to us mainly through Cicero's *Academica*. Middle Platonism revived the main themes of Speusippus and Xenocrates, but often used Stoic or neo-Pythagorean concepts to explain them. The influence of the Stoic Posidonius (135–50/51 B.C.) was strongly felt on the Academy in this period, and Platonism flourished at centers other than the Academy in Athens, most notably in Alexandria, with Eudorus (first century B.C.) and Philo of Alexandria (fl. A.D. 39).

After the death of Philo, the center of interest returned to Athens, where Plutarch of Chaeronia (A.D. c.45–c.125) studied with Ammonius at the Academy, although Plutarch spent most of his career at his home in nearby Boeotia. His many philosophical treatises, which are rich sources for the history of philosophy, are gathered under the title *Moralia;* his interest in ethics and moral education led him to write the *Parallel Lives* (paired biographies of famous Romans and Athenians), for which he is best known. After this period, the Academy ceased to be the name for a species of Platonic philosophy, although the school remained a center for Platonism, and was especially prominent under the leadership of the Neoplatonist Proclus (c.410–85).

accent, fallacy of. See INFORMAL FALLACY.

acceptance, as commonly conceived in philosophical literature, either a type of propositional attitude or a family thereof.

(1) On the most common understanding, to accept a proposition p for a context C is to have adopted a policy of using p as a premise for deciding what to do or to think in C. This 'premising conception' has been influenced by L. Jonathan Cohen. For example, a defense attorney is required to accept that her client is innocent within the juridical context. In the work of Dennett, 'opinion' denotes a narrower type of acceptance related merely to policies of utterance. The relation between acceptance and belief is controversial. Keith Frankish has argued that some acceptances qualify as beliefs. The more widespread view, however, is that acceptances differ from beliefs in virtue of occupying systematically different roles in motivating behavior and/or in virtue of having a different phenomenology.

(2) Some philosophers, e.g. Stalnaker, prefer to use 'acceptance' generically to denote a family of ways to treat a proposition as true. Here all kinds of beliefs and suppositions qualify as acceptances. This use is also fairly widespread.

(3) Among those who employ central alternative usages is Alston, who holds that to accept p is to engage in an activity leading to believing it. For Lehrer, to accept p is to believe it and endorse that belief. John Perry maintains that acceptance is a component of an attitude rather than an attitude in itself. In his preferred usage acceptance is the subjective psychological component of belief, in contrast to the content component of belief, which is a worldly state of affairs. Although central to specific philosophical debates, none of those usages have gained wider popularity. N.N.

accessibility, epistemic. See EPISTEMOLOGY.

accessibility between two worlds. See POSSIBLE WORLDS.

accident, a feature or property of a substance (e.g., an organism or an artifact) without which the substance could still exist. According to a common essentialist view of persons, Socrates' size, color, and integrity are among his accidents, while his humanity is not. For Descartes, thinking is the essence of the soul, while any particular thought a soul entertains is an accident. According to a common theology, God has no accidents, since all truths about him flow by necessity from his nature. These examples suggest the diversity of traditional uses of the notion of accident. There is no uniform conception; but the Cartesian view, according to which the accidents are modes of (ways of specifying) the essence of a substance, is representative. An important ambiguity concerns the identity of accidents: if Plato and Aristotle have the same weight, is that weight one accident (say, the property of weighing precisely 70 kilograms) or two (one accident for Plato, one for Aristotle)? Different theorists give different answers (and some have changed their minds). Issues about accidents have become peripheral in this century because of the decline of traditional concerns about substance. But the more general questions about necessity and contingency are very much alive. **See also** **CONTINGENT, ESSENTIALISM, PROPERTY.** S.J.W.

accident, fallacy of. See INFORMAL FALLACY.

accidental generalization. See LAWLIKE GENERALIZATION.

accidentalism, the metaphysical thesis that the occurrence of some events is either not necessitated or not causally determined or not predictable. Many determinists have maintained that although all events are caused, some nevertheless occur accidentally if only because the causal laws determining them might have been different. Some philosophers have argued that even if determinism is true, some events, such as a discovery, could not have been predicted, on grounds that to *predict* a discovery is to *make* the discovery.

The term may also designate a theory of individuation: that individuals of the same kind or species are numerically distinct in virtue of possessing some different accidental properties. Two horses are the same in essence but numerically distinct because one of them is black, e.g., while the other is white. Accidentalism presupposes the identity of indiscernibles but goes beyond it by claiming that accidental properties *account for* numerical diversity within a species. Peter Abelard criticized a version of accidentalism espoused by his teacher, William of Champeaux, on the ground that accidental properties depend for their existence on the distinct individuals in which they inhere, and so the properties cannot account for the distinctness of the individuals.

accidental property. See PROPERTY.

accidie (also acedia), apathy, listlessness, or ennui. This condition is problematic for the internalist thesis that, necessarily, any belief that one morally ought to do something is conceptually sufficient for having motivation to do it. Ann has long believed that she ought, morally, to assist her ailing mother, and she has dutifully acted accordingly. Seemingly, she may continue to believe this, even though, owing to a recent personal tragedy, she now suffers from accidie and is wholly lacking in motivation to assist her mother. **See also** **AKRASIA, MOTIVATIONAL INTERNALISM, SOCRATIC PARADOXES.** A.R.M.

Achilles paradox. See ZENO'S PARADOXES.

acosmism, a term formed on analogy to 'atheism', meaning the denial of the ultimate reality of the world. Ernst Platner used it in 1776 to describe Spinoza's philosophy, arguing that Spinoza did not intend to deny "the existence of the God head, but the existence of the world." Maimon, Fichte, Hegel, and others make the same claim. By the time of Feuerbach it was also used to characterize a basic feature of Christianity: the denial of the world or worldliness. **See also** **FICHTE, HEGEL, SPINOZA.** M.K.

action theory, the study of the ontological structure of human action, the process by which it originates, and the ways in which it is explained. Most human actions are acts of *commission:* they constitute a class of events in which a subject (the agent) brings about some change or changes. Thus, in moving one's finger, one brings it about that one's finger moves. When the change brought about is an ongoing process (e.g., the continuing appearance of words on a page), the behavior is called an *activity* (writing). An action of *omission* occurs when an agent refrains from performing an action of commission. Since actions of commission are events, the question of their ontology is in part a matter of the general ontology of change. An important issue here is whether what occurs when an action is performed should be viewed as abstract or concrete. On the first approach, actions are understood either as proposition-like entities (e.g., Booth's moving a finger) or as a species of universal – namely, an *act-type* (moving a finger). What "occurred" when Booth moved his finger in Ford's Theater on April 14, 1865, is held to be the abstract entity in question, and the entity is viewed as repeatable: precisely the same entity is held to have occurred on every other occasion of Booth's moving his finger. When actions are viewed as concrete, on the other hand, Booth's moving his finger in Ford's Theater is understood to be a non-repeatable particular, and the movement of the finger counts as an *act-token*, which instantiates the corresponding act-type. Concrete actions are time-bound: each belongs to a single behavioral episode, and other instantiations of the same act-type count as distinct events.

A second important ontological issue concerns the fact that by moving his finger, Booth also fired a gun, and killed Lincoln. It is common for more than one thing to be accomplished in a single exercise of agency, and how such doings are related is a matter of debate. If actions are understood as abstract entities, the answer is essentially foregone: there must be as many different actions on Booth's part as there are types exemplified. But if actions are viewed as particulars the same token can count as an instance of more than one type, and identity claims become possible. Here there is disagreement. *Fine-grained* theories of act individuation tend to confine identity claims to actions that differ only in ways describable through different modifications of the same main verb – e.g., where Placido both sings and sings loudly. Otherwise, different types are held to require different tokens: Booth's action of moving his finger is held to have generated or given rise to distinct actions of firing the gun and killing Lincoln, by virtue of having had as causal consequences the gun's discharge and Lincoln's death. The opposite, *coarse-grained* theory, however, views these causal relations as grounds for claiming Booth's acts were precisely identical. On this view, for Booth to kill Lincoln was simply for him to do something that caused Lincoln's death – which was in fact nothing more than to move his finger – and similarly for his firing the gun. There is also a compromise account, on which Booth's actions are related as part to whole, each consisting in a longer segment of the causal chain that terminates with Lincoln's death. The action of killing Lincoln consisted, on this view, in the entire sequence; but that of firing the gun terminated with the gun's discharge, and that of moving the finger with the finger's motion.

When, as in Booth's case, more than one thing is accomplished in a single exercise of agency, some are done *by* doing others. But if all actions were performed by performing others, an infinite regress would result. There must, then, be a class of *basic actions* – i.e., actions fundamental to the performance of all others, but not themselves done by doing something else. There is disagreement, however, on which actions are basic. Some theories treat bodily movements, such as Booth's moving his finger, as basic. Others point out that it is possible to engage in action but to accomplish less than a bodily movement, as when one tries to move a limb that is restrained or paralyzed, and fails. According to these accounts, bodily actions arise out of a still more basic mental activity, usually called *volition* or willing, which is held to constitute the standard means for performing all overt actions.

The question of how bodily actions originate is closely associated with that of what distinguishes them from involuntary and reflex bodily events, as well as from events in the inanimate world. There is general agreement that the crucial difference concerns the mental states that attend action, and in particular the fact that voluntary actions typically arise out of states of intending on the part of the agent. But the nature of the relation is difficult, and there is the complicating factor that intention is sometimes held to reduce to other mental states, such as the agent's desires and beliefs. That issue aside, it would appear that unintentional actions arise out of more basic actions that are intentional, as when one unintentionally breaks a shoelace by intentionally tugging on it. But how intention is first translated into action is much more problematic, especially when bodily movements are viewed as basic actions. One cannot, e.g., count Booth's moving his finger as an intentional action simply because he intended to do so, or even on the ground (if it is true) that his intention caused his finger to move. The latter might have occurred through a strictly autonomic response had Booth been nervous enough, and then the moving of the finger would not have counted as an action at all, much less as intentional. Avoiding such "wayward causal chains" requires accounting for the agent's voluntary control over what occurs in genuinely intentional action – a difficult task when bodily actions are held to be basic. Volitional accounts have greater success here, since they can hold that movements are intentional only when the agent's intention is executed through volitional activity. But they must sidestep another threatened regress: if we call for an activity of willing to explain why Booth's moving his finger counts as intentional action, we cannot do the same for willing itself. Yet on most accounts volition does have the characteristics of intentional behavior. Volitional theories of action must, then, provide an alternative account of how mental activity can be intentional.

Actions are explained by invoking the agent's reasons for performing them. Characteristically, a reason may be understood to consist in a positive attitude of the agent toward one or another outcome, and a belief to the effect that the outcome may be achieved by performing the action in question (though the term is also used for the contents of such attitudes, often of just one of them). Thus Emily might spend the summer in France out of a desire to learn French, and a belief that spending time in France is the best way to do so. Disputed questions about reasons include how confident the agent must be that the action selected will in fact lead to the envisioned outcome, and whether obligation represents a source of motivation that can operate independently of the agent's desires.

Frequently, more than one course of action is available to an agent. *Deliberation* is the process of searching out and weighing the reasons for and against such alternatives. When successfully concluded, deliberation usually issues in a decision, by which an intention to undertake one of the contemplated actions is formed. The intention is then carried out when the time for action comes. Much debate has centered on the question of how reasons are related to decisions and actions. As with intention, an agent's simply having a reason is not enough for the reason to explain her behavior: her desire to learn French notwithstanding, Emily might have gone to France simply because she was transferred there. Only when an agent does something *for* a reason does the reason explain what is done. It is frequently claimed that this bespeaks a causal relation between the agent's strongest reason and her decision or action. This, however, suggests a determinist stance on the free will problem, leading some philosophers to balk. An alternative is to treat reason explanations as teleological explanations, wherein an action is held to be reasonable or justified in virtue of the goals toward which it was directed. But positions that treat reason explanations as non-causal require an alternative account of what it is to decide or act for one reason rather than another.

act(ion)-token. See ACTION THEORY.

act(ion)-type. See ACTION THEORY, TYPE THEORY.

action verb, a verb applied to an agent and describing an activity, an action, or an attempt at or a culmination of an action. Verbs applying to agents may be distinguished in two basic ways: by whether they can take the progressive (continuous) form and by whether or not there is a specific moment of occurrence/completion of the action named by the verb. An *activity verb* is one describing something that goes on for a time but with no inherent endpoint, such as 'drive', 'laugh', or 'meditate'. One can stop doing such a thing but one cannot complete doing it. Indeed, one can be said to have done it as soon as one has begun doing it. An *accomplishment verb* is one describing something that goes on for a time toward an inherent endpoint, such as 'paint' (a fence), 'solve' (a problem), or 'climb' (a mountain). Such a thing takes a certain time to do, and one cannot be said to have done it until it has been completed. An *achievement verb* is one describing either the culmination of an activity, such as 'finish' (a job) or 'reach' (a goal); the effecting of a change, such as 'fire' (an employee) or 'drop' (an egg); or undergoing a change, such as 'hear' (an explosion) or 'forget' (a name). An achievement does not go on for a period of time but may be the culmination of something that does. Ryle singled out achievement verbs and state verbs (see below) partly in order to disabuse philosophers of the idea that what psychological verbs name must invariably be inner acts or activities modeled on bodily actions or activities. A *task verb* is an activity verb that implies attempting to do something named by an achievement verb. For example, to seek is to attempt to find, to sniff is to attempt to smell, and to treat is to attempt to cure. A *state verb* is a verb (not an action verb) describing a condition, disposition, or habit rather than something that goes on or takes place. Examples include 'own', 'weigh', 'want', 'hate', 'frequent', and 'teetotal'.

These differences were articulated by Zeno Vendler in *Linguistics and Philosophy* (1967). Taking them into account, linguists have classified verbs (and verb phrases) into four main aspectual classes, which they distinguish in respect to the availability and interpretation of the simple present tense, of the perfect tenses, of the progressive construction, and of various temporal adverbials, such as adverbs like 'yesterday', 'finally', and 'often', and prepositional phrases like 'for a long time' and 'in a while'. Many verbs belong to more than one category by virtue of having several related uses. For example, 'run' is both an activity and an accomplishment verb, and 'weigh' is both a state and an accomplishment verb. Linguists single out a class of *causative verbs*, such as 'force', 'inspire', and 'persuade', some of which are achievement and some accomplishment verbs. Such causative verbs as 'break', 'burn', and 'improve' have a correlative intransitive use, so that, e.g., to break something is to cause it to break.

act-object distinction. See BRENTANO, MEINONG.

act-object psychology, also called act-content-object psychology, a philosophical theory that identifies in every psychological state a mental act, a lived-through phenomenological content, such as a mental image or description of properties, and an intended object that the mental act is about or toward which it is directed by virtue of its content. The distinction between the act, content, and object of thought originated with Alois Höfler's *Logik* (1890), written in collaboration with Meinong. But the theory is historically most often associated with its development in Kazimierz Twardowski's *Zur Lehre vom Inhalt und Gegenstand der Vorstellung* ("On the Content and Object of Presentations," 1894), despite Twardowski's acknowledgment of his debt to Höfler.

Act-object psychology arose as a reaction to Franz Brentano's immanent intentionality thesis in his influential *Psychologie vom empirischen Standpunkt* ("Psychology from an Empirical Standpoint," 1874), in which Brentano maintains that intentionality is "the mark of the mental," by contrast with purely physical phenomena. Brentano requires that intended objects belong immanently to the mental acts that intend them – a philosophical commitment that laid Brentano open to charges of epistemological idealism and psychologism. Yet Brentano's followers, who accepted the intentionality of thought but resisted what they came to see as its detachable idealism and psychologism, responded by distinguishing the act-immanent phenomenological content of a psychological state from its act-transcendent intended object, arguing that Brentano had wrongly and unnecessarily conflated mental content with the external objects of thought.

Twardowski goes so far as to claim that content and object can never be identical, an exclusion in turn that is vigorously challenged by Husserl in his *Logische Untersuchungen* ("Logical Investigations," 1913, 1922), and by others in the phenomenological tradition who acknowledge the possibility that a self-reflexive thought can sometimes be about its own content as intended object, in which content and object are indistinguishable. Act-object psychology continues to be of interest to contemporary philosophy because of its relation to ongoing projects in phenomenology, and as a result of a resurgence of study of the concept of intentionality and qualia in philosophy of mind, cognitive psychology, and *Gegenstandstheorie*, or existent and non-existent intended object theory, in philosophical logic and semantics.

Adam de Wodeham. See WODEHAM.

Adams, Marilyn McCord (b.1943), American philosopher noted for her work in the history of medieval philosophy and in philosophy of religion. Adams is the author of four major books and many articles in her areas of expertise. *William Ockham* (1987) is a comprehensive account of Ockham's position in ontology, logic, epistemology, and natural philosophy, in comparison and contrast with the views of Aquinas, Duns Scotus, and Henry of Ghent, among others. In her major work on the problem of evil, *Horrendous Evils and the Goodness of God* (1999), Adams argues that it is possible that God is good to all persons by ensuring each a life that is a great good to the person, thus not merely balancing off horrendous evil with goods that are at least as great, but contributing to a great good in that individual's life. On her view, God may defeat all horrendous evil by empathically identifying with it. This idea is presented in a way designed to allow us to re-envision our suffering as a point of identification with God. In *Christ and Horrors: The Coherence of Christology* (2006), Adams develops her position on the problem of evil in a distinctively Christian way by formulating a view about the role of Christ in the defeat of evil.

In a recent historical work, *Some Later Medieval Theories of the Eucharist* (2010), Adams investigates thirteenth- and fourteenth-century transubstantiationist theories of the Eucharist, concentrating on Aquinas, Giles of Rome, Duns Scotus, and Ockham. Here she examines how their proposals for formulating the doctrine of transubstantiation provoked them to make significant revisions of Aristotelian theories about substance and accidents, causality and causal powers, kinds of change, and the structure and location of bodies. D.P.

Adams, Robert Merrihew (b.1937), American philosopher who has made seminal contributions to ethics, philosophy of religion, metaphysics, and the history of philosophy. Adams is best known for developing a theistic framework for ethics (*Finite and Infinite Goods*, 1999) and a complementary account of virtues (*A Theory of Virtue*, 2006), for defending metaphysical idealism ("Idealism Vindicated," in his *Persons: Human and Divine*, 2007), and for his scholarship on Leibniz (*Leibniz: Determinist, Theist, Idealist*, 1994). In metaphysics, Adams has defended primitive identity ("Primitive Thisness and Primitive Identity," 1979) and actualism ("Theories of Actuality," 1974), and as of this writing he has begun work on a "thick" concept of existence. In philosophy of religion, Adams rekindled debates on divine command theory, middle knowledge, the ontological argument, and the question whether God is obliged to create the best (*The Virtue of Faith and Other Essays in Philosophical Theology*, 1987). Following his retirement from Yale, a collection of papers by prominent philosophers engaging his work was published (*Metaphysics and the Good*, 2009). The volume includes an intellectual autobiography by Adams, which closes with a summary of his philosophical convictions: "I believe there is a metaphysically significant difference between appearance and reality; that there is a capital '*R*' Reality that grounds everything that appears; that it is mental; that it is good; and that doing philosophy can be a way of loving it."

Since earning his Ph.D. from Cornell in 1967, Adams has served on the faculties of the University of Michigan, UCLA, Yale, Oxford, and the University of North Carolina–Chapel Hill. He has delivered the Gifford and Wilde Lectures and is a fellow of the American Academy of Arts and Sciences (1991) and the British Academy (2006). He is also a founder of the Society for Christian Philosophers. S.New.

ādhyātman (Sanskrit, 'relating to or belonging to the self'), in early Hindu texts concerning such topics as knowledge of the self, meditating on that which appertains to the self, or spiritual exercise related to the self (*ādhyātma-yoga*). Later, it became a term for the Supreme Spirit, the Supreme Self, or the soul, which, in Indian thought, is other than the ego. In monistic systems, e.g. Advaita Vedanta, the *ādhyātman* is the one Self that is the impersonal Absolute (Brahman), a state of pure consciousness, ultimately the only Real. In dualist systems, e.g. Dvaita Vedanta, it is the true self or soul of each individual. R.N.Mi.

Adorno, Theodor Wiesengrund (1903–69), German philosopher and aesthetic theorist, one of the main philosophers of the first generation of the Frankfurt School of critical theory. With Horkheimer, Adorno gave philosophical direction to the Frankfurt School and its research projects in its Institute for Social Research. An accomplished musician and composer, Adorno first focused on the theory of culture and art, working to develop a non-reductionist but materialist theory of art and music in many essays from the 1930s. Under the influence of Walter Benjamin, he turned toward developing a "micrological" account of cultural artifacts, viewing them as "constellations" of social and historical forces.

As his collaboration with Horkheimer increased, Adorno turned to the problem of a self-defeating dialectic of modern reason and freedom. Under the influence of the seemingly imminent victory of the Nazis in Europe, this analysis focused on the "entwinement of myth and Enlightenment." *The Dialectic of Enlightenment* (1941) argues that instrumental reason promises the subject autonomy from the forces of nature, only to enslave it again by its own repression of its impulses and inclinations. The only way around this self-domination is "non-identity thinking," found in the unifying tendencies of a non-repressive reason. This self-defeating dialectic is represented by the striking image of Ulysses tied to the mast to survive his encounter with the Sirens. Adorno initially hoped for a positive analysis of the Enlightenment to overcome this genealogy of modern reason, but it was never developed. Instead, he turned to an increasingly pessimistic analysis of the growing reification of modern life and of the possibility of a "totally administered society."

Adorno held that "autonomous art" can open up established reality and negate the experience of reification. *Aesthetic Theory* (1970) develops this idea of autonomous art in terms of aesthetic form, or the capacity of the internal organization of art to restructure existing patterns of meaning. Authentic works of art have a "truth-value" in their capacity to bring to awareness social contradictions and antinomies. In *Negative Dialectics* (1966) Adorno provides a more general account of social criticism under the "fragmenting" conditions of modern rationalization and domination. These and other writings have had a large impact on cultural criticism, particularly through Adorno's analysis of popular culture and the "culture industry."

See also CRITICAL THEORY, FRANKFURT SCHOOL. J.Bo.

Advaita, also called Uttara Mīmāmsā, in Hinduism, the non-dualistic form of Vedanta. Advaita Vedanta makes an epistemological distinction (not a metaphysical one) between the level of appearance and the level of reality. This marks off how things appear versus how they are; there appear to be a multitude of distinct persons and physical objects, and a personal deity, whereas there is only ineffable Brahman. This doctrine, according to Advaita, is taught in the Upanishads and realized in an esoteric enlightenment experience called *moksha*. The opposing evidence provided by all experiences that (a) have a subject-consciousness-object structure (e.g., seeing a sunset) and evidence a distinction between what one experiences and oneself, or (b) have a subject/content structure (e.g., feeling pain) and evidence a distinction between oneself and one's states, is dismissed on the ground that these experiences involve "the making of distinctions." Critics claim that *moksha* itself, as an experience in which something allegedly is learned or grasped, also must involve "the making of distinctions." **See also** VEDANTA. K.E.Y.

adventitious ideas. See IDEA.

adverbial theory. See PERCEPTION.

adverbs, logic of, a logical system or an interpretation thereof that enables formalizing natural language sentences involving adverbial modification. First-order logic (on its customary interpretation) does not offer a satisfactory treatment of adverbs. The problem is this:

(1) Rachel spoke

is standardly formalized as '*Fa*'. But now consider

(2) Rachel spoke eloquently.

It seems that 'spoke eloquently' must be formalized as a single predicate wholly distinct from 'spoke' and so receive a fresh predicate symbol, yielding '*Ga*'. But this seems inadequate. First, the formalization obfuscates the explicit relation between the two verb phrases on account of their common element, 'spoke'. Second, representation of the logical form of these sentences should lay bare the entailment relations between them: here, the intuitive fact that (2) entails (1).

Davidson tackled these difficulties by postulating that action sentences involve a hidden variable ranging over events and bound by an existential quantifier. On this reading (1) should be paraphrased as

(3) There is an event x such that x is a speaking by Rachel.

Adverbs and adverbial clauses are thus treated as predicates of expressions that refer to events. Though cumbersome, this circumlocution promises to solve both aforementioned difficulties. For, paraphrasing (2), we now obtain

(4) There is an event x such that x is a speaking by Rachel and x is eloquent.

This brings to light that (1) and (2) share an element (the event of Rachel's speaking). Moreover, by representing the logical form of adverbially modified action sentences as an existentially quantified conjunction, Davidson ensures that the intuitive entailment relations are clear and obtain as a matter of logic.

Davidson's account has been influential, giving rise to *event semantics*. But it faces difficulties (of which Davidson was not unaware) – e.g., the inability to accommodate intensional adverbs (e.g., 'deliberately', 'greedily'). Also, adverbs like 'slowly' pose a problem. The underlying reason for both types of difficulty is that any given action can be described in many ways. Perhaps the best-known later development is the theory of adverbs proposed by Richmond Thomason and Robert Stalnaker. However, working in the tradition of Montague semantics, the Thomason-Stalnaker theory aims to provide a formal semantic treatment of adverbs, not to elaborate a *logic* of adverbs.

Aenesidemus. See SKEPTICISM, SKEPTICS.

aesthetic attitude, the appropriate attitude or frame of mind for approaching art (or nature or other objects or events) so that one might both appreciate its intrinsic perceptual qualities and, as a result, have an aesthetic experience. The aesthetic attitude has been construed in many ways: (1) as disinterested, so that one's experience of the work is not affected by any interest in its possible practical uses, (2) as a "distancing" of oneself from one's own personal concerns, (3) as the contemplation of an object, purely as an object of sensation, as it is in itself, for its own sake, in a way unaffected by any cognition or knowledge one may have of it. These different notions of aesthetic attitude have at times been combined within a single theory.

There is considerable doubt about whether there is such a thing as an aesthetic attitude. There is neither any special kind of action nor any special way of performing an ordinary action that ensures that we see a work as it "really is," and that results in our having an aesthetic experience. Furthermore, there are no *purely* sensory experiences, divorced from any cognitive content whatsoever. Criticisms of the notion of aesthetic attitude have reinforced attacks on aesthetics as a separate field of study within philosophy.

See also **AESTHETIC PROPERTY, AESTHETICS, BEAUTY.** S.L.F.

aesthetic form. See AESTHETIC FORMALISM, AESTHETICS.

aesthetic formalism, the view that in our interactions with works of art, form should be given primacy. Rather than taking 'formalism' as the name of one specific theory in the arts, it is better and more typical to take it to name that *type* of theory which emphasizes the *form* of the artwork. Or, since emphasis on form is something that comes in degrees, it is best to think of theories of art as ranged on a continuum of *more formalist* and *less formalist*. It should be added that theories of art are typically complex, including definitions of art, recommendations concerning what we should attend to in art, analyses of the nature of the aesthetic, recommendations concerning the making of aesthetic evaluations, etc.; and each of these components may be more formalist or less so.

Those who use the concept of form mainly wish to contrast the artifact itself with its relations to entities outside itself – with its representing various things, its symbolizing various things, its being expressive of various things, its being the product of various intentions of the artist, its evoking various states in beholders, its standing in various relations of influence and similarity to preceding, succeeding, and contemporary works, etc. There have been some, however, who in emphasizing form have meant to emphasize not just the artifact but the perceptible form or design of the artifact. Kant, e.g. in his theory of aesthetic excellence, not only insisted that the only thing relevant to determining the beauty of an object is its appearance, but, within the appearance, also stressed the *form*, the *design:* in visual art, not the colors but the design that the colors compose; in music, not the timbre of the individual sounds but the formal relationships among them.

It comes as no surprise that theories of music have tended to be much more formalist than theories of literature and drama, with theories of the visual arts located in between.

See also AESTHETICS. N.P.W.

aesthetic property, a property or quality such as being dainty, garish, graceful, balanced, charming, majestic, trite, elegant, lifeless, ugly, or beautiful. By contrast, non-aesthetic properties are properties that require no special sensitivity or perceptiveness to perceive – such as a painting's being predominantly blue, its having a small red square in a corner or a kneeling figure in the foreground, or the music's becoming louder at a given point. Sometimes it is argued that a special perceptiveness or taste is needed to perceive a work's aesthetic qualities, and that this is a defining feature of a property's being aesthetic. A corollary of this view is that aesthetic qualities cannot be defined in terms of non-aesthetic qualities, though some have held that aesthetic qualities supervene on non-aesthetic qualities. **See also** AESTHETICS, BEAUTY, SUPERVENIENCE. S.L.F.

aesthetics, the branch of philosophy that examines the nature of art and the character of our experience of art and of the natural environment. It emerged as a separate field of philosophical inquiry during the eighteenth century in England and on the Continent. Recognition of aesthetics as a separate branch of philosophy coincided with the development of theories of art that grouped together painting, poetry, sculpture, music, and dance (and often landscape gardening) as the same kind of thing, *les beaux arts*, or the fine arts. Baumgarten coined the term 'aesthetics' in his *Reflections on Poetry* (1735) as the name for one of the two branches of the study of knowledge, i.e. for the study of sensory experience coupled with feeling, which he argued provided a different type of knowledge from the distinct, abstract ideas studied by "logic." He derived it from the ancient Greek *aisthanomai* (to perceive), and "the aesthetic" has always been intimately connected with sensory experience and the kinds of feelings it arouses.

Questions specific to the field of aesthetics are: Is there a special attitude, the aesthetic attitude, which we should take toward works of art and the natural environment, and what is it like? Is there a distinctive type of experience, an aesthetic experience, and what is it? Is there a special object of attention that we can call the aesthetic object? Finally, is there a distinctive value, aesthetic value, comparable with moral, epistemic, and religious values? Some questions overlap with those in the philosophy of art, such as those concerning the nature of beauty, and whether there is a faculty of taste that is exercised in judging the aesthetic character and value of natural objects or works of art.

Aesthetics also encompasses the philosophy of art. The most central issue in the philosophy of art has been how to define 'art'. Not all cultures have, or have had, a concept of art that coincides with the one that emerged in Western Europe during the seventeenth and eighteenth centuries. What justifies our applying our concept to the things people in these other cultures have produced? There are also many pictures (including paintings), songs, buildings, and bits of writing that are not art. What distinguishes those pictures, musical works, etc., that are art from those that are not? Various answers have been proposed that identify the distinguishing features of art in terms of form, expressiveness, intentions of the maker, and social roles or uses of the object.

Since the eighteenth century there have been debates about what kinds of things count as "art." Some have argued that architecture and ceramics are not art because their functions are primarily utilitarian, and novels were for a long time not listed among the "fine arts" because they are not embodied in a sensuous medium. Debates continue to arise over new media and what may be new art forms, such as film, video, photography, performance art, found art, furniture, posters, earthworks, and computer and electronic art. Sculptures these days may be made out of dirt, feces, or various discarded and mass-produced objects, rather than marble or bronze. There is often an explicit rejection of craft and technique by twentieth-century artists, and the subject matter has expanded to include the banal and everyday, and not merely mythological, historical, and religious subjects as in years past. All of these developments raise questions about the relevance of the category of "fine" or "high" art.

Another set of issues in philosophy of art concerns how artworks are to be interpreted, appreciated, and understood. Some views emphasize that artworks are products of individual efforts, so that a work should be understood in light of the producer's knowledge, skill, and intentions. Others see the meaning of a work as established by social conventions and practices of the artist's own time, but which may not be known or understood by the producer. Still others see meaning as established by the practices of the users, even if they were not in effect when the work was produced.

Are there objective criteria or standards for evaluating individual artworks? There has been much disagreement over whether value judgments have universal validity, or whether there can be no disputing about taste, if value judgments are relative to the tastes and interests of each individual (or to some group of individuals who share the same tastes and interests). A judgment such as "This is good" certainly seems to make a claim about the work itself, though such a claim is often based on the sort of feeling, understanding, or experience a person has obtained from the work. A work's aesthetic or artistic value is generally distinguished from simply liking it. But is it possible to establish what sort(s) of knowledge or experience(s) any given work should provide to any suitably prepared perceiver, and what would it be to be suitably prepared? It is a matter of contention whether a work's aesthetic and artistic values are independent of its moral, political, or epistemic stance or impact.

Philosophy of art has also dealt with the nature of taste, beauty, imagination, creativity, representation, expression, and expressiveness; style; whether artworks convey knowledge or truth; the nature of narrative and metaphor; the importance of genre; the ontological status of artworks; and the character of our emotional responses to art.

Work in the field has always been influenced by philosophical theories of language or meaning, and theories of knowledge and perception, and continues to be heavily influenced by psychological and cultural theory, including versions of semiotics, psychoanalysis, cognitive psychology, feminism, and Marxism. Some theorists in the late twentieth century have denied that the aesthetic and the "fine arts" can legitimately be separated out and understood as separate, autonomous human phenomena; they argue instead that these conceptual categories themselves manifest and reinforce certain kinds of cultural attitudes and power relationships. These theorists urge that aesthetics can and should be eliminated as a separate field of study, and that "the aesthetic" should not be conceived as a special kind of value. They favor instead a critique of the roles that images (not only painting, but film, photography, and advertising), sounds, narrative, and three-dimensional constructions have in expressing and shaping human attitudes and experiences.

affirming the consequent. See FORMAL FALLACY.

***a fortiori* argument,** an argument that moves from the premises that everything which possesses (a) certain characteristic(s) will possess some further characteristic(s) and that certain things possess the relevant characteristic(s) to an eminent degree to the conclusion that *a fortiori* (even more so) these things will possess the further characteristic(s). The second premise is often left implicit, so *a fortiori* arguments are often enthymemes. An example of an *a fortiori* argument can be found in Plato's *Crito*: We owe gratitude and respect to our parents and so should do nothing to harm them. Athenians owe even greater gratitude and respect to the laws of Athens and so *a fortiori* should do nothing to harm those laws. **See also** ENTHYMEME, SYLLOGISM. R.P.

African philosophy, the philosophy produced by the preliterate cultures of Africa, distinctive in being unwritten. For someone interested in, say, Chinese or ancient Greek philosophy, written works are available; by contrast, African philosophy (with the exception of Ethiopian and ancient Egyptian philosophy) has no written philosophical works. African philosophical thought in the traditional setting is expressed in oral literature: proverbs, myths, and folktales, rituals, religious beliefs, art symbols, customs, and traditions. But the oral background of traditional African philosophical thought is surely not peculiar to this thought system, considered in comparison with the origins of the philosophical systems of many other cultures.

The term 'African' simply indicates that African philosophy derives from the cultural values, institutions, and experiences of the African people, that it is a philosophy which gives analytical attention to the intellectual foundations – ideas, beliefs, presuppositions – of African cultures and experiences, not one that is adhered to by all African peoples. The lack of written philosophical literature in Africa's cultural past is the outstanding reason for the persistent skepticism about the existence of African philosophy often exhibited by scholars. Some would withhold the term 'philosophy' from African traditional thought and reserve that term for the philosophical works written by contemporary African philosophers. There are others who, on the basis of (1) their own conception of philosophy, (2) their sense of the history of the development of philosophical ideas in other cultures, (3) their conviction about the importance of the universal character of the human capacity to wonder, or (4) their conviction that literacy is not a necessary condition for philosophizing, would apply 'philosophy' to African traditional thought, even though some of them would characterize it further as ethnophilosophy or folk philosophy.

Two assumptions about African traditional thought have earned it the labels 'ethnophilosophy' and 'folk philosophy'. One assumption is the alleged communal subscription to a monolithic set of ideas; the other is the alleged lack of individualist elements in traditional African thought. These assumptions have led some scholars to believe that African thought is a system of ideas or beliefs produced and unanimously held by a whole tribe (*ethnos*). It would be correct to say that in Africa's past, due to the lack of a doxographic tradition – a tradition of recorded opinions – there has been an absence of individual thinkers who are known, are identifiable, and can claim to have originated specific philosophical doctrines or arguments. However, it was such unidentifiable individual thinkers who created Africa's "collective thought." It is always an individual's idea or thought or proposition that is accepted and gains currency in the wider society. There is, strictly speaking, no such thing as "collective" thought, if this means that ideas are the production of a whole collectivity or group. Scholars, particularly anthropologists, who assert that African thought is collective fail to indicate how it was produced. Thought or ideas are the creation of individuals, identifiable in some cultures, unidentifiable in others. What seems to have happened in Africa is that due to the lack of a doxographic tradition, the ideas of unnamable (because unidentifiable) individuals that gained currency in the wider community became part of the pool of communal thought – a public philosophy – as if they were the thought or the production of a whole *ethnos* (a collectivity). A public philosophy may be said to be constituted by a corpus of basic ideas and beliefs, values, outlooks, feelings, fundamental convictions, and truths shared by a large section of a society. Despite the individual origins of thoughts, there is justification for considering such (individual) thoughts as, e.g., Greek or Akan or Yoruba, without assuming that every Greek or Akan or Bantu necessarily or unquestioningly adhered to those ideas. But those ideas from the minds of individuals would, nevertheless, appropriately be described as Greek, Akan, or Bantu by reason of the dynamic connection between the thoughts of individuals and their cultural background.

As to the central themes of African philosophy, one can indicate some of the persistent assumptions, ideas, and values embedded in African cultural and historical experiences. These include (1) *supernaturalism* – ideas about God and other spiritual entities conceived in African ontologies, the dualistic or monistic perception of the external world, the (alleged) religiosity or spirituality of African life; human destiny; and the moral life; (2) the concept of a *person*, linked with *communitarianism*, social and humanistic ethics, *moral personhood*, notions of the community, the common good, the nature of the good life, and the status of individuality; (3) *political ideas* – chiefship and traditional political authority, traditional ideas of democracy, democratic thought in a communitarian framework, consensual politics and decision making, and political legitimacy, political corruption, and political morality; and (4) *tradition and modernity* – the notion of culture, ethnicity and nationhood, of national culture and identity, and of technology, society, and values.

African ethics (moral philosophy) deserves special mention. Inquiries into the moral languages of most African peoples or cultures indicate that they lack a direct equivalent of 'ethics' or 'morality'; their word for 'character' refers to what others call 'ethics'. Thus, 'He has no morals' might be expressed by 'He has bad character'. In most moral evaluations, reference is made to the character of a person, suggesting the conviction that character is central in African ethics. African ethics is essentially a *character-ethics*.

The concept of a person in African thought embodies ethical presuppositions; there is thus a concept of moral personhood. This implies that there are certain basic moral norms and ideals to which the conduct of human beings, *if* they are persons, ought to conform, and that there are moral virtues individuals can and should display. An individual who fails to display them would not be considered a person (*onnye 'nipa*, in the Akan language of Ghana; or *Ki i se eniyan* in the Yoruba language of Nigeria), even though that individual would still be considered a *human being*.

Ethical humanism (humanitarianism), whose central focus is concern for the well-being of each member of society, is a major feature of African morality, born of the robust social life of African society and concerns about human dignity. This concern is the hub of the African axiological wheel. It nurtures the ethic of the common good but also prescribes the ethics of duty – to others and to the community – but not the ethics of rights. Although African ethics does not give short shrift to rights, it does not obsessively emphasize rights either. There is also an anti-supererogationist stance in African ethics, deriving from the social and humanitarian character of this ethical system. A supererogatory act is defined as 'beyond the call of duty'. In the perspective of African ethics, *if* an act is morally good and its performance would be conducive to the welfare of some individual human being (or beings), it cannot be morally optional; it ought to be performed. The fact that one may not be in a position to perform it does not make it optional and non-obligatory. In African ethical thought and practice, then, there would be no moral saints or moral heroes, for no moral acts are considered extraordinary, saintly, or heroic. The ethical perspective here runs counter to that of the West.

The foregoing themes and others have generated various ideas that must be critically analyzed and evaluated by contemporary African philosophers, who would in this way create a modern African philosophy with origins in the comprehensive culture and many-sided experiences of the African, yet aspects of which may be considered by other cultures to be worthwhile. Thanks to their inherited literary culture, African philosophers, through their own individual analyses and arguments, can contribute to the emergence of a modern African philosophy that would naturally comprise a multiplicity of philosophical ideas generated or inspired by the intellectual foundations of African cultures and experiences. An extensive critical evaluation of concepts and values of traditional thought can be the starting point. But the modern African philosophy will also have to include the conceptual responses to the circumstances, experiences, and problems of contemporary African societies. This aspect of the philosophical enterprise must deal with the critical analysis, interpretation, and assessment of the changes that traditional values and ideas are undergoing in response to the pressures, internal and external, weighing on them through the ethos of contemporary life. Still, African philosophy will not be a windowless monad impervious to external influences. It is conceivable, however – perhaps to be expected – that, linked to Africa's cultural and historical experiences, it will have some characteristics of its own. K.G.

āgama (Sanskrit, 'what has come down'), an authoritative religious text of an Indian sect. There are Hindu, Jain, and Buddhist *āgamas*. The Hindu *āgamas* fall into three main classes: Vaisnava texts concerning the worship of Vishnu, Saiva texts dealing with worship of Siva, and Tantric texts regarding worship of Sakti. Saivism, e.g., has twenty-eight *āgamas*. An *āgama* may give instructions regarding making temples or idols, offer meditation techniques, teach philosophical doctrines, or commend methods of worship. The Mahayana Buddhist term for the basic teachings of the Theravada Buddhist tradition is '*āgama*'. K.E.Y.

agape, unselfish love for all persons; also, an ethical theory according to which such love is the chief virtue, and actions are good to the extent that they express it, is sometimes called *agapism*. *Agape* is the Greek word most often used for love in the New Testament, and is often used in modern languages to signify whatever sort of love the writer takes to be idealized there. In New Testament Greek, however, it was probably a quite general word for love, so that any ethical ideal must be found in the text's substantive claims rather than in the linguistic meaning of the word. R.M.A.

***agathon*,** Greek word meaning 'a good' or 'the good'. From Socrates onward, *agathon* was taken to be a central object of philosophical inquiry; it has frequently been assumed to be the goal of all rational action. Plato in the simile of the sun in the *Republic* identified it with the Form of the Good, the source of reality, truth, and intelligibility. Aristotle saw it as *eudaimonia*, intellectual or practical virtue, a view that found its way, via Stoicism and Neoplatonism, into Christianity. Modern theories of utility can be seen as concerned with essentially the same Socratic question. R.C.

agent-based ethics. See VIRTUE ETHICS.

agent causation, the idea that the primary cause of an event is a substance; more specifically, causation by a substance, as opposed to an event. Thus a brick (a substance) may be said to be the cause of the breaking of the glass. The expression is also used more narrowly by Reid and others for the view that an action (or event) is caused by an exertion of power by some agent endowed with will and understanding. Thus a person may be said to be the cause of her action of opening the door. In this restricted sense (Reid called it "the strict and proper sense"), an agent-cause must have the power to cause the action or event *and* the power not to cause it. Moreover, it must be "up to" the agent whether to cause the event or not to cause it. (It is not "up to" the brick whether to cause or not to cause the breaking of the glass.) The restricted sense of agent causation developed by Reid is closely tied to the view that the agent possesses free will.

Medieval philosophers distinguished the internal activity of the agent from the external event produced by that activity. The former was called "immanent causation" and the latter "transeunt causation." These terms have been adapted by Chisholm and others to mark the difference between agent causation and event causation. The idea is that the internal activity is agent-caused by the person whose activity it is, whereas the external event is event-caused by the internal activity of the agent.

agent-relative. See UTILITARIANISM.

agnoiology (from Greek *agnoia*, 'ignorance'), the study of ignorance, its quality, and its conditions. L.P.P.

agnosticism (from Greek *a*-, 'not', and *gnāstos*, 'known'), term invented by Thomas Henry Huxley in 1869 to denote the philosophical and religious attitude of those who claim that metaphysical ideas can be neither proved nor disproved. Huxley wrote, "I neither affirm nor deny the immortality of man. I see no reason for believing it, but on the other hand, I have no means of disproving it. I have no *a priori* objection to the doctrine."

Agnosticism is a form of skepticism applied to metaphysics, especially theism. The position is sometimes attributed to Kant, who held that we cannot have knowledge of God or immortality but must be content with faith. Agnosticism should not be confused with atheism, the belief that no god exists.

Agriculture School. See XU XING.

Agrippan modes (or tropes), five strategies for confuting any argument whose aim is to demonstrate some philosophical truth or even to show that knowledge itself is possible. These strategies are associated with the tradition of Greek skepticism, specifically with Pyrrhonism. Our information is based on later accounts by Sextus Empiricus and Diogenes Laertius. Each historian provides two catalogues of the skeptics' modes, one consisting of ten strategies, the other of five. Diogenes attributes his shorter list to Agrippa. Nothing of Agrippa's writing survives, however, and Pyrrho apparently left no writings.

The Agrippan list consolidates the longer list of ten modes into two and adds three new modes. The focus of the longer list (a primer on relativism) is on the inevitability of conflicting judgments in matters of fact and value because of differences in sensory capacity, perceptual circumstances, social practices, and personal preferences. Two of Agrippa's three additions are formal strategies: devising an infinite regress and showing an argument to suffer from circularity. His third is pragmatic: treating any claim unsupported by argument as no better than a hypothesis.

Philosophical arguments emphasizing relativism have a pedigree which long preceded the skeptics. Neither were they the first to codify modes of reasoning, including the logical varieties. What is distinctive about Agrippa's modes, and Pyrrhonism generally, is the purpose that skeptical philosophers intended these modes to serve. Unlike sophists, they did not aim to win arguments but rather to silence them. Convinced that philosophical truth and even commonsense knowledge are unobtainable, and therefore that philosophical doctrines are pretensions, the skeptics emphasized the importance of settling for belief. In place of doctrine they offered a method of discovery whereby the practitioner, having witnessed the self-canceling clash of rival philosophical doctrines, would eventually suspend judgment (*epochē*) about their truth and worth and, through this process, achieve peace of mind (*ataraxia*). The Agrippan modes were not designed as blunt tools of rhetoric for use by closed minds (though they can also serve the anti-intellectual). Only through the careful study of philosophy will the skeptic acquire an open mind about its limits. This sentiment seems to echo in Wittgenstein's pronouncement two thousand years later: "The real discovery is the one which enables me to stop doing philosophy when I want to" (*Philosophical Investigations* I:133).

The so-called *Agrippan trilemma*, as propounded by the German philosopher Hans Albert (b.1921), reduces Agrippa's five modes to three. It contends that philosophical arguments aiming at demonstrative certainty face a triple threat, being forced into an infinite regress, blocked by circularity, or else snagged by the host of difficulties involving relativism and tenuous assumptions.

Agrippan trilemma. See AGRIPPAN MODES.

ahamkāra (Sanskrit, 'I-maker', 'I-crier'), in Hindu thought, the ego or faculty that gives the sense of 'I' or individual personality; by extension, egotism, pride, conceit. In the Sankhya and Yoga systems, it is the third element of ever-changing Nature evolving in creation. From it evolves the remainder of the phenomenal world. Other than Nature, which includes the individual intellect (*buddhi*), the faculty of perception (*manas*), the organs, and the senses, is the unchanging individual self (*puruśa, Ātman*). The human predicament results from the ignorant identification of oneself with Nature rather than the true self. In earlier texts the cosmic sense of *ahamkāra* dominates as the means by which the Creator formulates himself to create the world.

R.N.Mi.

ahantā (Sanskrit, 'indestructible', 'unchangeable', 'eternal'). In traditional Hindu philosophical thought, the truly real was thought to be indestructible and eternal. Thus, because the Upanishadic Brahman and its subjective counterpart, the *Ātman*, were regarded as the truly real, they were thought to be unchangeable and eternal. The Hindu religious classic, the Bhagavad Gita (probably written between the fifth and the second century B.C.), made *ahantā* a well-known concept through the teachings of Krishna, who advised Arjuna that even though one's body may perish one's soul is eternal and indestructible, thus implying that the human soul contains the essence of the divine reality. **See also** BHAGAVAD GITA, BRAHMAN.

D.K.C.

ahimsā (Sanskrit), traditionally and literally, nonviolence to living creatures; for modern Indian thinkers, a positive sense of kindness to all creatures. To the Jains, *ahimsā* was a vow to injure no living being (*jiva*) in thought, word, or deed. Many Buddhists practice *ahimsā* as a precept that denies the existence of the ego, since injuring another is an assertion of egoism. With the modern period, particularly Gandhi, *ahimsā* was equated with self-sacrificial love for all beings. For Gandhi it was the first vow of the *satyāgrahi*, the one who "held onto Truth," the nonviolent resister. **See also** GANDHI, JAINISM.

aitia (Greek, 'cause'). Originally referring to responsibility for a crime, this Greek term came to be used by philosophers to signify causality in a somewhat broader sense than the English 'cause' – the traditional rendering of *aitia* – can convey. An *aitia* is any answer to a why-question. According to Aristotle, how such questions ought to be answered is a philosophical issue addressed differently by different philosophers. He himself distinguishes four types of answers, and thus four *aitiai*, by distinguishing different types of questions: (1) Why is the statue heavy? Because it is made of bronze (material *aitia*). (2) Why did Persians invade Athens? Because the Athenians had raided their territory (moving or efficient *aitia*). (3) Why are the angles of a triangle equal to two right angles? Because of the triangle's nature (formal *aitia*). (4) Why did someone walk after dinner? Because (or for the sake) of his health (final *aitia*). Only the second of these would typically be called a cause in English. Though some render *aitia* as 'explanatory principle' or 'reason', these expressions inaptly suggest a merely mental existence; instead, an *aitia* is a thing or an aspect of a thing. **See also** ARISTOTLE, EXPLANATION. E.C.H.

ākāśa, Sanskrit word translated as 'ether' or 'space'. Indian philosophical systems recognized various ontological categories, including that of substance. *Ākāśa* was thought of as a substance because it was believed to be the substratum of sound. Because *ākāśa* was understood to transmit sound waves, the term is better translated as 'ether' than 'space', but scholars are not unanimous on this. *Ākāśa*, though extended in space, was viewed as a non-material substance. It was thought of as all-pervading, infinite, indivisible, and imperceivable, being inferred from the sensed quality of sound. D.K.C.

akrasia, also spelled *acrasia*, Greek term for weakness of will. *Akrasia* is a character flaw, also called incontinence, exhibited primarily in intentional behavior that conflicts with the agent's own values or principles. Its contrary is *enkrateia* (strength of will, continence, self-control). Both *akrasia* and *enkrateia*, Aristotle says, "are concerned with what is in excess of the state characteristic of most people; for the continent abide by their resolutions more, and the incontinent less, than most people can" (*Nicomachean Ethics* 1152a25–27). These resolutions may be viewed as judgments that it would be best to perform an action of a certain sort, or better to do one thing than another. *Enkrateia*, on that view, is the power (*kratos*) to act as one judges best in the face of competing motivation. *Akrasia* is a want or deficiency of such power. (Aristotle himself limited the sphere of both states more strictly than is now done, regarding both as concerned specifically with "pleasures and pains and appetites and aversions arising through touch and taste" [1150a9–10].)

Philosophers are generally more interested in incontinent and continent *actions* than in the corresponding states of character. Various species of incontinent or akratic behavior may be distinguished, including incontinent reasoning and akratic belief formation. The species of akratic behavior that has attracted most attention is uncompelled, intentional action that conflicts with a better or best judgment consciously held by the agent at the time of action. If, e.g., while judging it best not to eat a second piece of pie, you intentionally eat another piece, you act incontinently – provided that your so acting is uncompelled (e.g., your desire for the pie is not *irresistible*). Socrates denied that such action is possible, thereby creating one of the Socratic paradoxes.

In "unorthodox" instances of akratic action, a deed manifests weakness of will even though it *accords* with the agent's better judgment. A boy who decides, against his better judgment, to participate in a certain dangerous prank, might – owing to an avoidable failure of nerve – fail to execute his decision. In such a case, some would claim, his failure to act on his decision manifests weakness of will, or *akrasia*. If, instead, he masters his fear, his participating in the prank might manifest *strength* of will, even though his so acting conflicts with his better judgment.

The occurrence of akratic actions seems to be a fact of life. Unlike many such (apparent) facts, this one has received considerable philosophical scrutiny for nearly two and a half millennia. A major source of the interest is clear: akratic action raises difficult questions about the connection between thought and action, a connection of paramount importance for most philosophical theories of the explanation of intentional behavior. Insofar as moral theory does not float free of evidence about the etiology of human behavior, the tough questions arise there as well. Ostensible akratic action, then, occupies a philosophical space in the intersection of the philosophy of mind and moral theory.

See also ACTION THEORY, INTENTION, PRACTICAL REASONING, VOLITION. A.R.M.

akśara, in a variety of Hindu thought systems, the highest reality (in Sanskrit, 'imperishable'). From earliest times it also meant 'syllable', reflecting the search for the ultimate reality by Vedic priest-thinkers and the early primacy given to the sacred utterance as the support of the ritual order of the universe, later identified as the syllable *Om*. In later texts and the systematic thinkers it refers to the highest reality, which may be a personal supreme being or an impersonal absolute, such as the Highest Self (*Paramātman*) of Shankara (700–50). Non-technically, it can be used in any thought system of any entity believed to be imperishable. R.N.Mi.

ālaya-vijñāna, Sanskrit term literally meaning 'storehouse consciousness', a category developed by Indian Buddhist metaphysicians to solve some specific philosophical problems, notably those of delayed karmic effect and causation at a temporal distance. The *ālaya-vijñāna* "stores," in unactualized but potential form as "seeds," the results of an agent's volitional actions. These karmic "seeds" may come to fruition at a later time. Most Buddhists think of moments of consciousness (*vijñāna*) as intentional (having an object, being *of* something); the *ālaya-vijñāna* is an exception, allowing for the continuance of consciousness when the agent is apparently not conscious of anything (such as during dreamless sleep), and so also for the continuance of potential for future action during those times. **See also** BHAVANGA, VĀSANĀ. P.J.G.

Albert of Saxony (1316–90), terminist logician from lower Saxony who taught in the arts faculty at Paris, 1351–62. He never finished his theology degree, since, under the influence of Buridan and Nicholas of Oresme, he turned to mathematics, physics, and logic. He was a founder of the University of Vienna in 1365 and was bishop of Halberstadt from 1366. His works on logic include *Logic, Questions on the Posterior Analytics, Sophismata, Treatise on Obligations*, and *Insolubilia*. He also wrote questions on Aristotle's physical works and on John of Sacrobosco's *De Sphaera*, and short treatises on squaring the circle and on the ratio of the diameter to the side of a square. His work is competent but rarely original. **See also** TERMINIST LOGIC. J.Lo.

Albert the Great. See ALBERTUS MAGNUS.

Albertus Magnus, also called Albert the Great (c.1200–80), German Dominican philosopher-theologian who, as a Parisian master of theology, served on a commission that condemned the Talmud. He left Paris to found the first Dominican *studium generale* in Germany at Cologne in 1248. From 1252 until old age, Albert was repeatedly asked to be an arbiter and peacemaker. After serving briefly as bishop of Regensburg in 1260, he was ordered to preach the crusade of 1263–64 in Germany. He spent his last years writing in Cologne.

Albert contributed to philosophy chiefly as a commentator on Aristotle, although he occasionally reached different conclusions from Aristotle. Primarily, Albert was a theologian, as is evident from his extensive commentary on Peter Lombard's *Sentences* and his commentaries on the Old and New Testaments. As a theologian, he customarily developed his thought by commenting on traditional texts. For Albert, Aristotle offered knowledge ascertainable using reason, just as Scripture, based on God's word, tells of the supernatural. Albert saw Aristotle's works, many newly available, as an encyclopedic compendium of information on the natural universe; included here is the study of social and political conditions and ethical obligations, for Aristotelian "natural knowledge" deals with human nature as well as natural history. Aristotle is *the* Philosopher; however, unlike Holy Scripture, he must be corrected in places. Like Holy Scripture, though, Aristotle is occasionally obscure. To rectify these shortcomings one must rely on other authorities: in the case of Holy Scripture, reference is to the church fathers and established interpreters; in the case of Aristotle, to the Peripatetics. The term 'Peripatetics' extends to modern as well as ancient authors – al-Fārābī, Avicenna (Ibn-Sīnā), and Averroes (Ibn-Rushd), as well as Themistius and Alexander of Aphrodisias; even Seneca, Maimonides, and "our" Boethius are included.

For the most part, Albert saw Plato through the eyes of Aristotle and Averroes, since apart from the *Timaeus* very little of Plato's work was available in Latin. Albert considered the *Liber de causis* a work of Aristotle, supplemented by al-Fārābī, Avicenna, and al-Ghazālī and translated into Latin. When he commented on the *Liber de causis*, Albert was not aware that this Neoplatonic work – which speaks of the world emanating from the One as from a first cause – was based on Proclus and ultimately on Plotinus. But Albert's student, Aquinas, who had better translations of Aristotle, recognized that the *Liber de causis* was not an Aristotelian work.

Albert's metaphysics, which is expounded in his commentaries on Aristotle's *Metaphysics* and on the *Liber de causis*, contains profoundly contradictory elements. His inclination to synthesis led him to attempt to reconcile these elements – as on social and ecclesiastical questions he often sought peace through compromise. In his *Metaphysics* and *Physics* and in his *On the Heavens* and *On Generation and Corruption*, Aristotle presented the world as ever-changing and taught that an unmoved mover ("thought thinking itself") maintained everything in movement and animation by allowing its spiritual nature to be seen in all its cold, unapproachable beauty. The *Liber de causis*, on the other hand, develops the theory that the world emanates from the One, causing everything in the world in its pantheistic creativity, so that the caused world returns in mystic harmony to the One. Thus Albert's Aristotelian commentaries, begun in 1251–52, culminated in 1265 with his commentary on a work whose pseudo-Aristotelian character he was unable to recognize. Nevertheless, the Christian Neoplatonism that Albert placed on an Aristotelian basis was to exert an influence for centuries.

In natural philosophy, Albert often arrived at views independent of Aristotle. According to Aristotle's *Physics*, motion belongs to no single category; it is incomplete being. Following Avicenna and Averroes, Albert asks whether "becoming black," for example – which ceases when change ceases and blackness is finally achieved – differs from blackness essentially (*essentia*) or only in its being (*esse*). Albert establishes, contrary to Avicenna, that the distinction is only one of being.

In his discussions of place and space, stimulated by Avicenna, Albert also makes an original contribution. Only two dimensions – width and breadth – are essential to place, so that a fluid in a bottle is framed by the inner surface of the bottle. According to Albert, the significance of the third dimension, depth, is more modest, but nonetheless important. Consider a bucket of water: its base is the essential part, but its round walls maintain the cohesion of the water.

For Aristotle, time's material foundation is distinct from its formal definition. Materially, the movement of the fixed stars is basic, although time itself is neither movement nor change. Rather, just as before and after are continuous in space and there are earlier and later moments in movement as it proceeds through space, so time – being the number of motion – has earlier and later moments or "nows." The material of time consists of the uninterrupted flow of the indivisible nows, while time's form and essential expression is number. Following al-Farābī and Avicenna, Albert's interpretation of these doctrines emphasizes not only the uninterrupted continuity of the flow of "nows," but also the quantity of time, i.e. the series of discrete, separate, and clearly distinct numbers. Albert's treatment of time did not lend itself well to later consideration of time as a dimension; his concept of time is therefore not well suited to accommodate our unified concept of space-time.

The use of the pseudo-Aristotelian *De proprietatibus elementorum* in *De causis proprietatum elementorum* gave Albert's worldview a strong astrological flavor. At issue here is how the planets influence the earth and mankind. Particularly important is the influence of Jupiter and Saturn on fire and the seas; when increased, it could produce fiery conflagrations, and when circumscribed, floods.

Albert was encyclopedic: a scientist and scholar as well as a philosopher and theologian. In addition to the works mentioned, he produced commentaries on Pseudo-Dionysius, a *Summa de creaturis*, a *Summa theologica*, and many other treatises. Unlike that of other commentators, his exposition was continuous, an extensive paraphrase; he provided a complete Latin and Christian philosophy. Even in his lifetime, he was a named authority; according to Roger Bacon, his views were often given as much weight as those of Aristotle, Avicenna, and Averroes. His students or followers include Aquinas, Ulrich of Strassburg (d.1278?), Theodoric of Freiberg (d.1310?), Giles of Lessines (d.1304?), Meister Eckhart (d.1328), Johannes Tauler (d.1361), Henry Suso (d.1366), and Jan van Ruysbroeck (d.1381).

Albinus. See COMMENTARIES ON PLATO, MIDDLE PLATONISM.

alchemy, a quasi-scientific practice and mystical art, mainly ancient and medieval, that had two broad aims: to change baser metals into gold and to develop the elixir of life, the means to immortality. Classical Western alchemy probably originated in Egypt in the first three centuries A.D. (with earlier Chinese and later Islamic and Indian variants) and was practiced in earnest in Europe by such figures as Paracelsus and Newton until the eighteenth century. Western alchemy addressed concerns of practical metallurgy, but its philosophical significance derived from an early Greek theory of the relations among the basic elements and from a religious-allegorical understanding of the alchemical transmutation of ores into gold, an understanding that treats this process as a spiritual ascent from human toward divine perfection. The purification of crude ores (worldly matter) into gold (material perfection) was thought to require a transmuting agent, the *philosopher's stone*, a mystical substance that, when mixed with alcohol and swallowed, was believed to produce immortality (spiritual perfection). The alchemical search for the philosopher's stone, though abortive, resulted in the development of ultimately useful experimental tools (e.g., the steam pump) and methods (e.g., distillation). Alembert, Jean Le Rond d'. See D'ALEMBERT.

alethic modalities, propositional modalities related to *truth* (Greek, *aletheia*). Traditionally, there are four fundamental alethic modalities: necessity, contingency, possibility, and impossibility. Given the notion of truth *simpliciter*, any one of these can be defined in terms of any of the others. Thus, a proposition p is necessary if it is true but not contingent; p is contingent if it is true but its negation not-p is possible; p is possible if not-p is not impossible; and, completing the circle, p is impossible if not-p is necessary. Despite this interdefinability, necessity and possibility are generally taken to be conceptually more fundamental, and most systems of alethic modal logic take one of the two as primitive and define the other in terms of it.

In systems of alethic modal logic, typically, $\Box p$ expresses that p is necessary and $\Diamond p$ that p is possible. Three of these systems are particularly well known, and differ chiefly in regard to the logical properties of *complex*, or *iterated*, modalities, as illustrated in the proposition *It is necessary that it is possible that it is possible that pigs fly* – formally, where p represents *pigs fly*, $\Box\Diamond\Diamond p$. The weakest of these systems, usually called T, features the principle that necessities are, in fact, true, $\Box q \rightarrow q$. In T, every modality, iterated or not, is logically distinct from every other. The stronger system S4 adds to T the principle that necessities are themselves necessary, $\Box q \rightarrow \Box\Box q$. In S4, iterations of either basic modality are redundant. So, in S4, the above proposition is equivalent to *It is necessary that it is possible that pigs fly* – formally, in S4, $\Box\Diamond\Diamond p$ is logically equivalent to $\Box\Diamond p$. The strongest and perhaps most widely accepted system, S5, adds to T the principle that possibilities are necessary, $\Diamond q \rightarrow \Box\Diamond q$. In S5, all iteration is redundant. Thus, in S5, the two propositions above are both equivalent simply to *It is possible that pigs fly* – formally, in S5, $\Box\Diamond\Diamond p$ and $\Box\Diamond p$ are both logically equivalent to $\Diamond p$.

Alexander, Samuel (1859–1938), Australian-born British philosopher. He was educated at Balliol College, Oxford, and taught for most of his career at the University of Manchester. His aim, most fully realized in *Space, Time, and Deity* (1920), was to provide a realistic account of the place of mind in nature. He described nature as a series of levels of existence where irreducible higher-level qualities emerge inexplicably when lower levels become sufficiently complex. At its lowest level reality consists of space-time, a process wherein points of space are redistributed at instants of time and which might also be called pure motion. From complexities in space-time matter arises, followed by secondary qualities, life, and mind. Alexander thought that the still-higher quality of deity, which characterizes the whole universe while satisfying religious sentiments, is now in the process of emerging from mind. **See also** PHILOSOPHY OF MIND. J.W.A.

Alexander of Aphrodisias (fl. A.D. c.200), Greek philosopher, one of the foremost commentators on Aristotle in late antiquity. He exercised considerable influence on later Greek, Arabic, and Latin philosophy through to the Renaissance. On the problem of universals, Alexander endorses a brand of conceptualism: although several particulars may share a single, common nature, this nature does not exist *as a universal* except while abstracted in thought from the circumstances that accompany its particular instantiations. Regarding Aristotle's notorious distinction between the "agent" and "patient" intellects in *On the Soul* III.5, Alexander identifies the agent intellect with God, who, as the most intelligible entity, makes everything else intelligible. As its own self-subsistent object, this intellect alone is imperishable; the human intellect, in contrast, perishes at death. Of Alexander's many commentaries, only those on Aristotle's *Metaphysics* A-Λ, *Prior Analytics* I, *Topics, On the Senses*, and *Meterologics* are extant. We also have two polemical treatises, *On Fate* and *On Mixture*, directed against the Stoics; a psychological treatise, the *De anima* (based on Aristotle's); as well as an assortment of essays (including the *De intellectu*) and his *Problems and Solutions*. Nothing is known of Alexander's life apart from his appointment by the emperor Severus to a chair in Aristotelian philosophy between 198 and 209. **See also** ARISTOTLE, CONCEPTUALISM, STOICISM. V.C.

Alexander of Hales (c.1185–1245), English Franciscan theologian, known as the *Doctor Irrefragabilis*. Alexander was the first to teach theology by lecturing on the *Sentences* of Peter Lombard, and his emphasis on speculative theology initiated the golden age of Scholasticism. Alexander wrote commentaries on the Psalms and the Gospels; his chief works include his *Glossa in quattuor libros sententiarum, Quaestiones disputatatae antequam esset frater*, and *Quaestiones quodlibetales*. Alexander did not complete the *Summa fratris Alexandri;* Pope Alexander IV ordered the Franciscans to complete the *Summa Halesiana* in 1255.

Master of theology in 1222, Alexander played an important role in the history of the University of Paris, writing parts of Gregory IX's *Parens scientiarum* (1231). He also helped negotiate the peace between England and France in 1235–36. Later in 1236 he gave up his position as canon of Lichfield and archdeacon of Coventry to become a Franciscan, the first Franciscan master of theology; his was the original Franciscan chair of theology at Paris. Among the Franciscans, his most prominent disciples include St. Bonaventure, Richard Rufus of Cornwall, and John of LaRochelle, to whom he resigned his chair in theology near the end of his life. R.W.

Alexandrian School, those Neoplatonic philosophers contemporary with and subsequent to Proclus (A.D. 412–85) who settled in Alexandria and taught there. They include Hermeias (fl. c.440), Proclus's fellow student of Syrianus; Hermeias's son Ammonius (either 435–517 or 445–526); and Ammonius's three pupils, John Philoponus (c.490–575), Simplicius (writing after 532), and Asclepius (mid-sixth century). Later Alexandrians include Olympiodorus (495/505–after 565) and the Christians Elias (fl. c.540) and David (late sixth century). All these worked exclusively or primarily on the exegesis of Aristotle. Damascius (c.456–540) also took lectures from Ammonius at some time between 475 and 485, but in his doctrine he belongs much more to the Athenian tradition. Simplicius, on the other hand, while he moved to Athens to teach, remains more in the Alexandrian tradition.

Ever since Karl Praechter, who was influenced by a Hegelian view of historical development, the Alexandrian Platonists have been seen as professing a simpler form of metaphysics than the Athenian School, and deliberately avoiding controversy with the powerful Christian establishment in Alexandria by confining themselves largely to logic, mathematics, and the exegesis of Aristotle. There is a certain manifest truth in this picture, but modern scholarship (in particular that of Ilsetraut Hadot) has done much to show that even in Ammonius's commentaries on Aristotle there lurks distinctive Neoplatonic doctrine, so that the contrast with the Athenian School has become somewhat blurred. The School may be said to have come to an end with the departure of Stephanus to take up the chair of philosophy in Constantinople in about 610.

al-Fārābī, Abu Nasr (also called Abunaser and, in Latin, Alpharabius) (870–950), Islamic philosopher born in Turkestan who studied and taught in Baghdad when it was the cultural capital of the Islamic world. He was responsive to the philosophical and scientific legacy of late antiquity. Al-Fārābī was highly instrumental in effecting a transition of Greek philosophy, last publicly known in its entirety in sixth-century Alexandria, into Islamic culture. Despite ongoing opposition because of philosophy's identification with pagan and Christian authors, al-Fārābī succeeded in naturalizing Western philosophy in the Islamic world, where it retained vitality for the next three hundred years. Al-Fārābī became known as "the second teacher," after Aristotle the main source of philosophical information. His summaries and interpretations of the teachings of Aristotle and Plato were widely read, and his attempt at synthesizing their views was very influential. Believing in the universal nature of truth and holding Plato and Aristotle in the highest esteem, he minimized their differences and adopted Neoplatonic teachings that incorporated elements of both traditions.

Unlike the first philosopher of the Islamic world, the ninth-century al-Kindī, al-Fārābī possessed full Arabic translations of many of the most important texts of classical times and of some major Hellenistic commentaries on them. His own commentaries and digests of the works of Plato and Aristotle made them more accessible to later generations of scholars, even as his relatively independent treatises established a high standard of logical rigor and subtlety for later Muslim and Jewish philosophers. Avicenna found his *Metaphysics* commentary indispensable for understanding Aristotle's text, while Maimonides recommended all his writings, calling them "pure flour." Medieval Scholastic thought, however, was more interested in Averroes and Avicenna than in al-Fārābī. Contemporary scholars such as Leo Strauss and Muhsin Mahdi have emphasized the esoteric nature of al-Fārābī's writings, seen as critical for understanding much of medieval Islamic and Jewish philosophy.

Al-Fārābī's main interests lay in logic and political theory. He understood that the *Organon* was just that, a universal instrument for understanding and improving reasoning and logical discourse. Against the traditional grammarians of Islam, he argued for the value-free and neutral nature of Greek logic, while against the theologians of Islam, the *mutakallimun*, he emphasized the difference between their dialectical type of discourse and the preferred demonstrative syllogism of the philosophers. Much of the responsibility for the separation between Islamic theology and philosophy may be attributed to al-Fārābī, who avoided engaging religious dogmas and specifically Muslim beliefs as much as possible. He was able to accommodate belief in prophecy and revelation to a general theory of emanation, though he made no special claims for the prophet of Islam. His general view of religion was that it was a popular and symbolic representation of philosophical ideas, often designed by philosophers. The influence of Plato's *Republic* in this and other areas of political philosophy is evident, though al-Fārābī's *Principles of the Views of the Citizens of the Best State* manages to give an Islamic coloration to Platonic teachings. Al-Fārābī's metaphysical beliefs are more problematical still, and he was reputed to have disowned his earlier belief in the immortality of the soul.

al-Ghazālī, Abu Hamid (1058–1111). Islamic philosopher, theologian, jurist, and mystic. He was born in Khurasan and educated in Nishapur, then an intellectual center of eastern Islam. He was appointed the head of a seminary, the newly founded Nizamiyah of Baghdad, where he taught law and theology. His exposure to logic and philosophy led him to seek a certainty in knowledge beyond that assumed by his profession. At first he attempted to address his problem academically, but after five years in Baghdad he resigned, left his family, and embarked on the mystic's solitary quest for *al-Haqq* (Arabic for 'the truth', 'the True One'). As a Sufi he wandered for ten years through many of Islam's major cities and centers of learning, finally returning to Nishapur and to teaching theology before his death.

Al-Ghazālī's literary and intellectual legacy is particularly rich and multifaceted. In the catholicity of his work and the esteem in which he is held within Islam he may be compared to Aquinas and Maimonides in the Christian and Jewish traditions respectively. His *Revivification of the Religious Sciences* is still considered a major theological compendium. His mystical treatises also have retained their popularity, as has his much celebrated autobiography, *The Deliverance from Error*. This book chronicles his lifelong quest for truth and certainty, and his disappointment with the premises of dogmatic theology, both orthodox Sunni and heterodox Shiite thought, as well as with the teachings of the philosophers. The light of truth came to him, he believed, only through divine grace; he considered his senses and reasoning powers all susceptible to error.

It was this pervasive skepticism that led him to investigate philosophy's claims to knowledge. He first composed a summa of philosophical teachings, based primarily on the views of Avicenna, and called it *The Intentions of the Philosophers*. He later published a detailed and penetrating critique of these views, *The Incoherence of the Philosophers*. Averroes arose later in Muslim Spain to defend philosophy, particularly that of Aristotle, calling his book *The Incoherence of the Incoherence*. Averroes' work was more appreciated in the West, however, which also preferred al-Ghazālī's *Intentions* to his *Incoherence*. The former, shorn of its polemical purpose and thus appearing as a philosophical summa, was translated by Dominicus Gundissalinus as *Logica et philosophia Algazelis*, giving al-Ghazālī a reputation in the West as at least a sometime advocate of philosophy. His attack upon the physics and metaphysics of his day, which was an amalgam of Aristotelian and Neoplatonic doctrines, was firmly rooted in Aristotelian logic, and anticipates Hume in understanding the non-necessary nature of causal relationships. For al-Ghazālī, the world as a whole proceeds not by any eternal or logical necessity, but by the will of God. That will is indefensible on philosophical grounds, he believed, as is the philosophers' notion of divine omniscience. Their god cannot on their terms be related to the world, and is ultimately redundant logically. What is regarded as miraculous becomes possible, once nature is understood to have no autonomy or necessary entailments.

algorithm, a clerical or effective procedure that can be applied to any of a class of certain symbolic inputs and that will in a finite time and number of steps eventuate in a result in a corresponding symbolic output. A function for which an algorithm (sometimes more than one) can be given is an algorithmic function. The following are common examples: (a) given n, finding the nth prime number; (b) differentiating a polynomial; (c) finding the greatest common divisor of x and y (the Euclidean algorithm); and (d) given two numbers x, y, deciding whether x is a multiple of y. When an algorithm is used to calculate values of a numerical function, as in (a), (b), and (c), the function can also be described as algorithmically computable, effectively computable, or just computable. Algorithms are generally agreed to have the following properties – which made them essential to the theory of computation and the development of the Church-Turing thesis – (i) an algorithm can be given by a finite string of instructions, (ii) a computation device (or agent) can carry out or compute in accordance with the instructions, (iii) there will be provisions for computing, storing, and recalling steps in a computation, (iv) computations can be carried out in a discrete and stepwise fashion (in, say, a digital computer), and (v) computations can be carried out in a deterministic fashion (in, say, a deterministic version of a Turing machine). **See also** CHURCH'S THESIS, COMPUTABILITY, COMPUTER THEORY. F.A.

algorithmic function. See ALGORITHM.

alienation, in a theological sense, remoteness from God; with respect to social phenomena, the individual experience of isolation from, and lack of power regarding, social processes; and in the individual-psychological sense, the loss of normal evaluative self-experience. In the Young Hegelians' critique of religion and theology, alienation figures as a necessary intermediate step toward the self-realization of individual autonomy and of the essence of the human species. Marx transfers this complex notion of alienation into an anthropologically basic structure; for him alienation is rooted in the capitalist mode of production: in a society based on division of labor, private property, and wage labor, human beings are alienated from their own activity, the product of their labor, their species nature, and other human individuals. In such circumstances, human beings systematically fail to develop relations of recognition that are a necessary element of humans' self-realization. **See also** HEGEL, MARX, RECOGNITION. M.Q.

aliorelative. See RELATION.

al-Kindī, Abu Yusuf, in Latin, Alkindus (c.800–70), Arab philosopher who was an early and prominent supporter of philosophical studies among the Muslims. He combined a noble Arab lineage with an influential position in the caliphate during a critical period for the translation and propagation of Greek sciences in Arabic. Known as "the philosopher of the Arabs," he more than any other scholar of his generation was responsible, as a patron, book collector, editor, and writer, for the acceptance of philosophy, despite its foreign and non-Islamic Greek source. Later writers surpassed him in knowledge of philosophy, and his numerous epistles, treatises, and books were eventually left in limbo. Of the 250 titles recorded in his name on an unusual variety of subjects, most are lost. About forty survive in a poor state, full of uncertain readings and other textual problems. Nevertheless, al-Kindī's works provide ample evidence of his close interest in Aristotle and to an extent Plato.

Unlike later philosophers in the Islamic world, he firmly believed he could combine literal Koranic religious doctrines and Greek philosophical concepts. Among his best-known philosophical works is *On First Philosophy* (English translation by A. Ivry, 1974), whose theme is that the noblest part of philosophy is first philosophy, which is knowledge of the First Truth and the First Cause. Al-Kindī includes an extended demonstration of the finiteness of the universe, time, and motion and the consequent infinitude of a creator who was their cause, who is the pure unity that is the ultimate source of all else, and yet who, in al-Kindī's mind, brings the world into being *ex nihilo*. In *On the Number of Aristotle's Books*, he separates prophetic knowledge from ordinary, discursive philosophy: prophets know intuitively without effort or time.

See also ARABIC PHILOSOPHY. P.E.W.

Allais's paradox, a puzzle about rationality devised by Maurice Allais (b.1911). Leonard Savage (1917–71) advanced the sure-thing principle, which states that a rational agent's ranking of a pair of gambles having the same consequence in a state *S* agrees with her ranking of any other pair of gambles the same as the first pair except for having some other common consequence in *S*. Allais devised an apparent counterexample with four gambles involving a 100-ticket lottery. The table lists prizes in units of $100,000.

	Ticket Numbers		
Gambles	**1**	**2–11**	**12–100**
A	5	5	5
B	0	25	5
C	5	5	0
D	0	25	0

Changing *A*'s and *B*'s common consequence for tickets 12–100 from 5 to 0 yields *C* and *D* respectively. Hence the sure-thing principle prohibits simultaneously preferring *A* to *B*, and *D* to *C*. Yet most people have these preferences, which seem coherent. This conflict generates the paradox. Savage presented the sure-thing principle in *The Foundations of Statistics* (1954). Responding to preliminary drafts of that work, Allais formulated his counterexample in "The Foundations of a Positive Theory of Choice Involving Risk and a Criticism of the Postulates and Axioms of the American School" (1952).

allegory of the cave. See PLATO.

Allison, Henry (b.1937), prominent interpreter of Kant's philosophy and author of several groundbreaking works on Kant's critical system. Allison's account of transcendental idealism as an essentially epistemic position is among the most influential recent readings of Kant. *Kant's Transcendental Idealism* (1983, rev. 2004) defends Kant's position in the *Critique of Pure Reason*, arguing that the key to making sense of transcendental idealism is the notion of the epistemic conditions on experience. For Allison, these epistemic conditions arise from Kant's commitment to a discursive account of cognition, in which two elements – sensible intuitions and concepts – make human experience possible. Focusing on the discursiveness of cognition, Allison argues that Kant's idealism is not a metaphysical view but a methodological position, in which the distinction between appearances and things in themselves reflects two different ways of considering the same objects, rather than marking an ontological divide.

In addition to seminal work on transcendental idealism, Allison has published important interpretations of Kant's practical philosophy and aesthetics. *Kant's Theory of Freedom* (1990) explores transcendental freedom and autonomy, and their relation to moral agency in the *Groundwork* and *Critique of Practical Reason*. Allison defends the idea that intentional actions require an element of spontaneity, in which agents freely incorporate maxims into their will. *Kant's Theory of Taste* (2001) focuses on the *Critique of Judgment*, and in particular Kant's account of aesthetic judgment. Allison proposes that the purposiveness of reflective judgment is crucial to making sense of judgments of taste. In addition to his treatments of Kant's three *Critiques*, Allison has published two collections of essays, *Idealism and Freedom* (1996) and *Essays on Kant* (2012), and a commentary, *Kant's Groundwork for the Metaphysics of Morals* (2011). He has also recently turned to Hume, in *Custom and Reason in Hume: A Kantian Reading of the First Book of the* Treatise (2008). P.T.

all-things-considered reason. See REASONS FOR ACTION.

Alpharabius. See AL-FĀRĀBĪ.

al-Rāzī, Abu Bakr, in Latin, Rhazes (c.854–925 or 932), Persian physician, philosopher, and chemist. He headed the hospital in Rayy, his birthplace, and later in Baghdad, often returning to Rayy, where he died. A learned Galenist and critic of Galen, he brought the same empirical, Hippocratic spirit to medicine that he had used in transmuting alchemy into a (Neoplatonically) naturalistic art. His medical works, including the first treatise on smallpox, drew on extensive (and compassionate) clinical experience and omnivorous reading – both reading and observation preserved in the twenty-five-volume *Hāwī*, translated in 1279 as the *Continens*. Al-Rāzī's mildly ascetic ethics springs from hedonic prudential considerations and from his atomism. In keeping with the Epicureanism he might have imbibed from Galenic sources, he rejects special prophecy as imposture, arguing that reason, God's gift to all alike, is sufficient guidance. (Only differences of interest and application separate the subtle devices of artisans from those of intellectuals.) God, the world Soul, time, space, and matter are all eternal substances. Nature originates from Soul's irrational desire for embodiment, which is her only way of learning that her true homeland is the intellectual world. God's gift of intelligence gave order to the movements she stirred up at the creation, and allows her escape from a world in which pains outweigh pleasures and death is surcease. For one who engages in philosophy "creatively, diligently, and persistently" will inevitably surpass his predecessors; and anyone who thinks independently is assured of both progress and immortality. L.E.G.

Alston, William P. (1921–2009), American philosopher widely acknowledged as one of the most important contemporary epistemologists and one of the most important philosophers of religion of the twentieth century. He is particularly known for his argument that putative perception of God is epistemologically on all fours with putative perception of everyday material objects.

Alston graduated from Centenary College in 1942 and was honorably discharged from the U.S. Army in 1946. A fine musician, he had to choose between philosophy and music. Philosophy won out; he received his Ph.D. from the University of Chicago and began his philosophical career at the University of Michigan, where he taught for twenty-two years. Since 1980 he has taught at Syracuse University. Although his dissertation and some of his early work were on Whitehead, he soon turned to philosophy of language (*Philosophy of Language*, 1964). Since the early 1970s Alston has concentrated on epistemology and philosophy of religion.

In epistemology he has defended foundationalism (although not classical foundationalism), investigated epistemic justification with unusual depth and penetration, and called attention to important levels distinctions. His chief works here are *Epistemic Justification* (1989), a collection of essays; and *The Reliability of Sense Perception* (1993). His chief works in philosophy of religion are *Divine Nature and Human Language* (1989), a collection of essays on metaphysical and epistemological topics; and *Perceiving God* (1991). The latter is a magisterial argument for the conclusion that experiential awareness of God, more specifically perception of God, makes an important contribution to the grounds of religious belief. Alston not only produced scholarly work, but served as a founder of the Society of Christian Philosophers, a professional society with more than 1,100 members, and the founding editor of *Faith and Philosophy*.

alternative denial. See SHEFFER STROKE.

Althusser, Louis (1918–90), French Marxist philosopher whose publication in 1965 of two collections of essays, *Pour Marx* (“For Marx”) and *Lire le Capital* (“Reading *Capital*”), made him a sensation in French intellectual circles and attracted a large international readership. The English translations of these texts in 1969 and 1970, respectively, helped shape the development of Marxist thought in the English-speaking world throughout the 1970s.

Drawing on the work of non-positivist French historians and philosophers of science, especially Bachelard, Althusser proclaimed the existence of an “epistemological break” in Marx’s work, occurring in the mid-1840s. What preceded this break was, in Althusser’s view, a prescientific theoretical humanism derived from Feuerbach and ultimately from Hegel. What followed it, Althusser maintained, was a science of history, a development as monumental, potentially, as the rise of the new sciences of nature in the seventh century. Althusser argued that the nature and even the existence of this new kind of science had yet to be acknowledged, even by Marx himself. It therefore had to be reconstructed from Marx’s writings, *Das Kapital* especially, and also discerned in the political practice of Lenin and other like-minded revolutionaries who implicitly understood what Marx intended. Althusser did little, however, to elaborate the content of this new science. Rather, he tirelessly defended it programmatically against rival construals of Marxism. In so doing, he took particular aim at neo-Hegelian and “humanistic” currents in the larger Marxist culture and (implicitly) in the French Communist Party, to which he belonged throughout his adult life.

After 1968, Althusser’s influence in France faded. But he continued to teach at l’École Normale Superieure and to write, making important contributions to political theory and to understandings of “ideology” and related concepts. He also faced increasingly severe bouts of mania and depression. In 1980, in what the French courts deemed an episode of “temporary insanity,” he strangled his wife. Althusser avoided prison, but spent much of the 1980s in mental institutions. During this period he wrote two extraordinary memoirs, *L’avenir dure longtemps* (“The Future Lasts Forever”) and *Les faits* (“The Facts”), published posthumously in 1992.

altruism. See EGOISM.

ambiguity, a phonological (or orthographic) form having multiple (two or more) meanings (senses, characters, semantic representations) assigned by the language system. A *lexical ambiguity* (a semantic kind) occurs when a lexical item (word) is assigned multiple meanings by the language. It includes (a) *homonymy*, i.e. distinct lexical items having the same sound or form but different senses – ‘knight’/’night’, ‘lead’ (n.)/’lead’ (v.), ‘bear’ (n.)/’bear’ (v.); and (b) *polysemy*, i.e. a single lexical item having multiple senses – ‘lamb’ (the animal)/’lamb’ (the flesh), ‘window’ (glass)/’window’ (opening). The distinction between homonymy and polysemy is problematic.

A *structural ambiguity* (a syntactic kind) occurs when a phrase or sentence is correlated by the grammar of the language with distinct constituent structures (phrase markers or sequences of phrase markers). Example: ‘Competent women and men should apply’ – ‘$[_{\text{NP}}[_{\text{NP}}$Competent women] and men] . . .’ vs. ‘$[_{\text{NP}}$ Competent$[_{\text{NP}}$ women and men]] . . .’, where NP stands for ‘noun phrase’.

A *scope ambiguity* is a structural ambiguity deriving from alternative interpretations of scopes of operators (see below). Examples: 'Walt will diet and exercise only if his doctor approves' – sentence operator scope: doctor's approval is a necessary condition for both diet and exercise (wide scope 'only if') vs. approval necessary for exercise but not for dieting (wide scope 'and'); 'Bertie has a theory about every occurrence' – quantifier scope: one grand theory explaining all occurrences ('a theory' having wide scope over 'every occurrence') vs. all occurrences explained by several theories together ('every occurrence' having wide scope). The *scope of an operator* is the shortest full subformula to which the operator is attached. Thus, in '$(A \& B)\vee C$', the scope of '&' is '$(A \& B)$'. For natural languages, the scope of an operator is what it C-commands. (X C-commands Y in a tree diagram provided the first branching node that dominates X also dominates Y.) An occurrence of an operator has *wide scope* relative to that of another operator provided the scope of the former properly includes the scope of the latter. Examples: in '$\sim(A \& B)$', '~' has wide scope over '&'; in '$(\exists x)(\forall y)\ Fxy$', the existential quantifier has wide scope over the universal quantifier.

A *pragmatic ambiguity* is duality of use resting on pragmatic principles such as those which underlie reference and conversational implicature; e.g., depending on contextual variables, 'I don't know that he's right' can express doubt or merely the denial of genuine knowledge.

ambiguity, elliptic. See ELLIPSIS.

Ambrose, Saint, known as Ambrose of Milan (c.339–97), Roman church leader and theologian. While bishop of Milan (374–97), he not only led the struggle against the Arian heresy and its political manifestations, but offered new models for preaching, for scriptural exegesis, and for hymnody. His works also contributed to medieval Latin philosophy. Ambrose's appropriation of Neoplatonic doctrines was noteworthy in itself, and it worked powerfully on and through Augustine. Ambrose's commentary on the account of creation in Genesis, his *Hexaemeron*, preserved for medieval readers many pieces of ancient natural history and even some elements of physical explanation. Perhaps most importantly, Ambrose engaged ancient philosophical ethics in the search for moral lessons that marks his exegesis of Scripture; he also reworked Cicero's *De officiis* as a treatise on the virtues and duties of Christian living. M.D.J.

American philosophy, the distinctive philosophical tradition that developed in America and having as its centerpiece American pragmatism; or, in a wider sense, philosophy as practiced in America, understood in terms of the relevant historical facts.

In the eighteenth and nineteenth centuries, the era of Jonathan Edwards, speculative thought in America was largely in the hands of theologians. What pure philosophy there was (mainly Locke's and Berkeley's) was primarily in the service of theology. Gradually, however, philosophy was emancipated from its religious moorings. One of the early emancipations was a kind of nature spiritualism articulated by a group of Cambridge/Boston former ministers (Emerson, Parker, Thoreau) under the banner 'Transcendentalism'. It was a truncated form of Romanticism (Kant via Coleridge) that seems to have perennial appeal and persists to this day in thinkers like Stanley Cavell. Scottish realism gradually gained ascendancy in the colleges. Although "the philosophers" were still usually clergymen and often college presidents, their philosophical interests turned to epistemology and morality rather than theology.

The last third of the nineteenth century was marked by the ascendancy of Kant and Hegel as philosophical models. Idealism functioned as a halfway house between religion and secularism. Many who taught philosophy in the new universities had studied philosophy in Germany and were trained in the various post-Kantian and neo-Kantian idealist options. Lotze and Wundt had a marked influence on those who were to play major roles in the development of philosophy in America. Moreover, those who emerged as the major philosophers of the period, whether trained in German or not, were broadly speaking in the idealist tradition. Josiah Royce studied in Germany (primarily with Lotze) and then at Johns Hopkins, where he lectured on "The Return to Kant." C. S. Peirce, by most measures the foremost American philosopher, went to Harvard, where for three years he studied Kant's *Critique of Pure Reason* for hours daily. He conceived his lifelong philosophical project as rethinking Kant's critical philosophy but now with a proper knowledge of physics, mathematics, and logic. Rejecting the "thing-in-itself," he constructed an objective idealism continuous with and a completion of a scientific understanding of the world. William James, Peirce's friend throughout his life, shied away from the term 'idealism' because of its absolutist connotation but developed a voluntaristic personal idealism influenced by both Kant and British empiricism. John Dewey matriculated at Johns Hopkins, where he came under the influence of the Hegelian George Sylvester Morris. Dewey developed a system of evolutionary idealism in the tradition of the British idealists Caird and Green. So at the turn of the twentieth century, philosophy in America was firmly in the tradition of the various forms of post-Kantian idealism, but it was an idealism heavily influenced by Lotze and Wundt and thus very congenial to science.

The synergy created by the dynamic interaction of "idealism" and "science" gave rise to America's distinctive contribution to world philosophy – pragmatism. Pragmatism is grounded at one end in classical idealism but is also inspired and profoundly influenced by the new scientific approach to understanding. Specifically, Peirce was trained as a scientist and spent most of his adult life as a research scientist for the U.S. Coast and Geodetic Survey. He was basically a physicist and a mathematical logician who saw his pragmatism as a theory of *meaning* for theoretical terms, but his overall metaphysical vision was a version of objective idealism. James was trained as a medical scientist. His first appointment at Harvard was as professor of physiology, then experimental psychology, and only finally philosophy. His overall metaphysical view was a voluntaristic personal idealism, and his pragmatism was a theory of *truth* fitting this perspective. Dewey was initially a Hegelian. Although not trained as a scientist, he came under the influence of G. Stanley Hall at Johns Hopkins, where he became convinced that the empirical methodology of science was the key to his systematic elaboration of his idealistic philosophy. His pragmatism featured a scientific dynamic notion of value, oriented toward resolving real problems. So initially pragmatism and scientific idealism went hand in hand. Soon, however, he made a transition from pragmatic idealism to pragmatic naturalism. While at the University of Michigan, Dewey read and was profoundly influenced by Darwin, studied the biological James of *The Principles of Psychology*, and interacted with the scientifically oriented George Herbert Mead, who became his lifelong collaborator. Dewey and Mead then moved to the University of Chicago, where they formed the "Chicago School of Pragmatism," which was theoretically naturalistic and practically social reformist. Dewey then moved to Columbia University, where pragmatism was firmly embedded in naturalism.

But pragmatism was not the only game in town. The metaphysical debate of the time was between "naturalism" (Dewey) and "materialism" (Santayana), with idealism no longer central. Epistemology was also a major concern. All idealisms were suspect, and most of those who were not pragmatists were realists of some kind. Cooperative volumes emerged. *New Realism* (1912) contained papers by Perry, Holt, Montague, Pitkin, Spaulding, and Marvin; each articulated a "direct realism" positing no mental intermediaries between the knower and the object known. *Critical Realism* (1920), with papers by Drake, Lovejoy, Pratt, Rogers, Strong, Santayana, and R. W. Sellars, defended a direct though mediated realism wherein the object is directly known but through intermediaries. These philosophers also exhibited a style: historically grounded system building was being gradually replaced by careful, piecemeal philosophizing.

In addition to these metaphysical and epistemological developments, the early decades of the twentieth century saw an ascendency of mathematical logic and a general privileging of natural science that enriched the new spirit of naturalism. In his short but productive academic career, Peirce had designed an entire logic curriculum for Johns Hopkins and convinced Royce to introduce a similar emphasis on formal logic at Harvard. This emphasis was enriched by visiting lectures by Bertrand Russell delivering the same message. C. I. Lewis was the beneficiary of all this when, at Harvard, he firmly established symbolic logic as an earmark of its program. At the same time, Morris Cohen, Ernest Nagel, and Dewey himself were making the case for the scientific reconstruction of philosophy.

This emphasis on science and logic prepared the way for the next development of mainstream philosophy in America, and that stage involved the influx of like-minded scientific philosophers from Europe. The Vienna Circle of the 1920s and 1930s was a complex sociological reality made up of several kindred German and Austrian philosophical traditions. Members met regularly and organized several international conferences with the theme of establishing a new, truly scientific philosophy. They were powerful thinkers whose stance was naturalistic, scientifically informed, and logically driven and whose project was to provide a clear scientific alternative to the speculative idealism characteristic of German philosophy. However, as the specter of the Third Reich loomed, these radical thinkers needed a new home if their revolution in philosophy was to take root.

The temper of philosophy in America in the 1930s provided the proper environment for such a philosophical orientation. Naturalistic pragmatism and logical empiricism had a natural affinity, and from 1930 to 1936 the *Journal of Philosophy* featured numerous articles noting this affinity. Leading American philosophy departments were not slow to issue invitations. Given their quality as philosophers, the members of the Vienna Circle not only were welcome additions to the major centers of philosophy in America but soon played leading roles therein. This was not the influx of an alien philosophical temperament but a matter of kindred spirits grafting onto a tradition already in place. Specifically, Carnap went to Harvard, Chicago (1936), and finally UCLA; Reichenbach to UCLA (1938); Tarski to the University of California, Berkeley (1940); Bergmann to Iowa (1938); Hempel to Chicago (1937), Columbia, Yale, Princeton, and Pittsburgh; Frank to Harvard (1939), where he founded the Institute for the Unity of Science; and Feigl to Iowa (1930) and then Minnesota, where he founded the Minnesota Center for the Philosophy of Science. Several became presidents of the American Philosophical Association. The grafting of these scientifically oriented Europeans onto the like-minded American tree was facilitated by the collaboration of Carnap and Charles Morris at the University of Chicago to produce Otto Neurath's *International Encyclopedia of Unified Science*. Morris was a student of Mead and a proponent of "scientific philosophy" who recognized the affinity of logical empiricism and naturalistic pragmatism. This series played an important role in institutionalizing the melding of the earlier pragmatic tradition with the new logical empiricism. It contained monographs by Dewey, Neurath, Carnap, Nagel, Frank, Edel, Hempel, and Morris, among others.

The next stage in the development of mainstream philosophy in America (beginning in the 1950s) also involved a European influence, but this time from Oxford rather than Vienna, and the immigration was one of ideas more than persons. The philosophical perspective of the Wittgenstein of the *Investigations* had made its way from Cambridge to Oxford and there, in the persons of Ryle, Austin, Hart, Hampshire, Strawson, Berlin, and Grice, "ordinary language philosophy" flourished. This ordinary language tradition had a natural affinity with what may be seen as the other side of pragmatism – the commonsense side with its aversion to speculation. There was a rich interchange between Oxford and America, with luminaries from each giving lectures and seminars in the other venue. Most important, Austin gave his influential lectures *How to Do Things with Words* at Harvard in 1954–55, and Norman Malcolm, Wilfrid Sellars, and John Searle spent formative years at Cambridge and Oxford before taking influential positions in America. Just as the logical empiricists found fertile soil in the scientific, empirical, and logical dimensions of pragmatism, so the later wave of analysis resonated positively with pragmatism's commonsense core.

After these two waves of what came to be called "analytic philosophy," mainstream American philosophy was firmly defined in the major departments, at which most leading philosophers would be trained for the remainder of the century. The scientific, logical, and commonsense dimensions of both pragmatism and naturalism undergirded different strands of this technical infusion, resulting in a rich, varied philosophical mainstream. Philosophy had become both more technical and more piecemeal, with two models of precision coexisting: to the project of exploring the conceptual foundations of mathematics, logic, and science was added the project of probing the conceptual foundations of everyday life.

Given this history, it should not be surprising that philosophy of science, epistemology, and philosophy of language came to be central in American philosophy. In the 1950s through the 1970s, figures emerged who recapitulated much of this multifaceted tradition and contributed to America's occupying center stage on the world philosophical scene. Quine, Goodman, and Wilfrid Sellars, though they tied together the various strands of the mainstream in their own persons, were joined by the American students of the original Vienna immigrants to create an even tighter weave. Putnam and Wesley Salmon were students of Reichenbach; Richard Jeffery was a student of Carnap; and both Adolf Grunbaum and Nicholas Rescher were students of Hempel. These well-positioned figures also had prolific students who continued this multifaceted discussion for the remainder of the twentieth century. Nozick, van Fraassen, Davidson, David Lewis, and Kripke became major voices in the core areas of epistemology, philosophy of science, philosophy of language, and philosophy of mind. In addition, these areas became richer and more technical by interacting with cognate sciences such as cognitive science, linguistics, computer science, mathematics, and the natural sciences.

Toward the end of the twentieth century the exclusionary aspect of mainstream philosophy in America softened and the more speculative traditional questions reappeared. The doctrinal core of both logical empiricism and ordinary language philosophy dissolved under continual self-criticism, leaving only a “style” or a “stance” as the operative meaning of ‘analytic’. The core area of metaphysics was reborn in both the pre-Kantian (David Lewis and Kripke) and post-Kantian varieties (McDowell and Brandom), and philosophy of mathematics (Paul Benacerraf), philosophy of religion (Plantinga), and aesthetics (Danto) became niche specializations.

Although the earlier integration of logical empiricism and analysis put a damper on substantive moral philosophy, metaethics was a lively area, with Stevenson, Hare, and Frankena as major players. All this changed in 1971 with the publication of Rawls’s *A Theory of Justice*. Political philosophy was reborn, and substantive moral philosophy in general had a great awakening. Nozick’s “rebuttal” of Rawls immediately followed, and then Dworkin, Raz, and other students of H. L. A. Hart (who split his time between Oxford and America) revitalized the philosophy of law in both philosophy departments and leading law schools. This naturalized neo-Kantianism was joined by the rebirth of virtue theory to provide ethical alternatives to the utilitarianism that had been entrenched throughout the century. Partial émigrés Foot, Williams, and MacIntyre were central to the rebirth of substantive moral and political philosophy. Rawls’s later work, culminating in *Political Liberalism* (1993), reengaged the spirit of pragmatism as articulated in the political philosophy of Dewey.

Mainstream philosophy in America, especially since the 1970s, has witnessed continual internal critique. Hempel and Putnam provided critiques of their own earlier views. Quine produced a critique of some fundamental tenets of logical positivism, Sellars of empiricist epistemology, and Feyerabend of classical philosophy of science. These critiques created serious tremors. Stephen Kuhn’s *The Structure of Scientific Revolutions* (1962) caused an earthquake; Rorty’s *Philosophy and the Mirror of Nature* (1979) had a Janus-like effect, perceived as an annoyance from inside philosophy and an earthquake from outside. Kuhn’s historical contextualization of science was seen to cast doubt on the uncritical deference to science paid by mainstream naturalistic philosophers, and Rorty’s more sweeping broadside against both science and mainstream philosophy spawned the “neo-pragmatist” movement by connecting major Continental philosophers and literary critics with his reinterpretation of philosophy in America from Dewey to Rawls.

The boundaries between mainstream philosophy and other traditions have become considerably more porous, and the renewed interest in serious history (particularly Greek and modern European) has greatly contributed to a new pluralism in philosophy in America. By the end of the twentieth century even the term ‘analytic’ as applied to mainstream philosophy in America seemed primarily genealogical, and the term ‘postanalytic’ was often invoked. Nonetheless, in the early twenty-first century, most of the quite various and vigorous research programs that emanate from major American departments and journals manifest the distinctive marks of their complex mainstream lineage. There is an irony in “the rebirth of pragmatism” that has brought the twentieth century full circle. The designation masks a diversity which ranges from the “right pragmatism” of those who are pro-science (Rescher) to the “left pragmatism” of those who are pro-conversation (Rorty), recapitulating the two sides of pragmatism that were there from the beginning. There is a further irony in the fact that ‘American philosophy’ in this narrow sense of the term (Peirce, James, Dewey, and Mead) is now a specialization operating on the fringes of mainstream philosophy in America.

Ameriks, Karl (b.1947), leading scholar of Kant and German idealism. He was president of the Central Division of the American Philosophical Association (2004–2005) and is coeditor of the series *Cambridge Texts in the History of Philosophy* (1994–) and of the annual *International Yearbook of German Idealism* (2003–).

Ameriks’s first book, *Kant’s Theory of Mind* (1982, rev. ed. 2001), is the classic interpretation of Kant’s paralogisms, arguing that a minimal rationalist core is consistent with Kant’s criticisms of the dogmatic claims of rational psychology. *Kant and the Fate of Autonomy* (2000) argues that Kant’s philosophy is best understood as a modest system, that Reinhold’s appropriation of Kant fundamentally influenced the reception of Kant, that Fichte departed from Kant in giving “short” arguments for idealism based on generic concepts (such as ‘representation’ and ‘intuition’) rather than “long” arguments based on specific features of space and time. It also contains classic presentations and analyses of Hegel’s criticisms of

Kant's theoretical and practical philosophy. *Interpreting Kant's Critiques* (2003) collected many of Ameriks's important papers on Kant. Ameriks argues that Kant's transcendental deduction is a regressive argument, that Kant fundamentally shifted his position with respect to arguments for our freedom from the *Groundwork* to the *Critique of Practical Reason*, and that, in an important sense, aesthetic judgments can be genuinely objective. In *Kant and the Historical Turn* (2006), Ameriks argues for a non-phenomenalist, commonsense realist interpretation of Kant's transcendental idealism and shows the importance of Reinhold, especially for the emergence of historicity as a philosophical issue. *Kant's Elliptical Path* (2012) argues for continuity in Kant's position from the 1760s, even as he develops his "revolutionary" doctrine of transcendental idealism. Ameriks's translation (with Steve Naragon) of Kant's *Lectures on Metaphysics* (1997) has contributed to a renaissance of scholarly interest in Kant's more traditional metaphysical doctrines. E.Wa.

Ammonius. See COMMENTARIES ON ARISTOTLE.

Ammonius Saccas (early third century A.D.), Platonist philosopher who taught in Alexandria. He apparently served early in the century as the teacher of the Christian philosopher Origen. He attracted the attention of Plotinus, who came to the city in 232 in search of philosophical enlightenment (Porphyry, *Life of Plotinus* 3). Ammonius (the epithet 'Saccas' seems to mean 'the bagman') was undoubtedly a charismatic figure, but it is not at all clear what, if any, were his distinctive doctrines, though he seems to have been influenced by Numenius. He wrote nothing, and may be thought of, in E. R. Dodds's words, as the Socrates of Neoplatonism. **See also NEOPLATONISM.** J.M.D.

analysis, the process of breaking up a concept, proposition, linguistic complex, or fact into its simple or ultimate constituents. That on which the analysis is done is called the *analysandum*, and that which does the analysis is called the *analysans*. A number of the most important philosophers of the twentieth century, including Russell, Moore, and (the early) Wittgenstein, argued that philosophical analysis is the proper method of philosophy. But the practitioners of analytic philosophy have disagreed about what kind of thing is to be analyzed. For example, Moore tried to analyze sense-data into their constituent parts. Here the analysandum is a complex psychological fact, the having of a sense-datum. More commonly, analytic philosophers have tried to analyze concepts or propositions. This is conceptual analysis. Still others have seen it as their task to give an analysis of various kinds of sentences – e.g., those involving proper names or definite descriptions. This is linguistic analysis. Each of these kinds of analysis faces a version of a puzzle that has come to be called the *paradox of analysis*. For linguistic analyses, the paradox can be expressed as follows: for an analysis to be adequate, the analysans must be synonymous with the analysandum; e.g., if 'male sibling' is to analyze 'brother', they must mean the same; but if they are synonymous, then 'a brother is a male sibling' is synonymous with 'a brother is a brother'; but the two sentences do not seem synonymous. Expressed as a dilemma, the paradox is that any proposed analysis would seem to be either inadequate (because the analysans and the analysandum are not synonymous) or uninformative (because they are synonymous). **See also ANALYTIC PHILOSOPHY, DEFINITION, MATHEMATICAL ANALYSIS, MEANING, PARADOX OF ANALYSIS, RUSSELL.** R.Fo.

analytic philosophy, an umbrella term currently used to cover a diverse assortment of philosophical techniques and tendencies. As in the case of chicken-sexing, it is relatively easy to identify analytic philosophy and philosophers, though difficult to say with any precision what the criteria are. Analytic philosophy is sometimes called Oxford philosophy or linguistic philosophy but these labels are, at least, misleading. Whatever else it is, analytic philosophy is manifestly not a school, doctrine, or body of accepted propositions. Analytic philosophers tend largely, though not exclusively, to be English-speaking academics whose writings are directed, on the whole, to other English-speaking philosophers. They are the intellectual heirs of Russell, Moore, and Wittgenstein, philosophers who self-consciously pursued "philosophical analysis" in the early part of the twentieth century. Analysis, as practiced by Russell and Moore, concerned not language per se, but concepts and propositions. In their eyes, while it did not exhaust the domain of philosophy, *analysis* provided a vital tool for laying bare the logical form of reality. Wittgenstein, in the *Tractatus Logico-Philosophicus* (1921), contended, though obliquely, that the structure of language reveals the structure of the world; every meaningful sentence is analyzable into atomic constituents that designate the fine-grained constituents of reality. This "Tractarian" view was one Wittgenstein was to renounce in his later work, but it had considerable influence within the Vienna Circle in the 1920s, and in the subsequent development of logical positivism in the 1930s and 1940s. Carnap and Ayer, both exponents of positivism, held that the task of philosophy was not to uncover elusive metaphysical truths, but to provide analyses of scientific sentences. (Other sentences, those in ethics, for instance, were thought to lack "cognitive significance.") Their model was Russell's theory of descriptions, which provided a technique for analyzing away apparent commitments to suspicious entities. Meanwhile, a number of former proponents of analysis, influenced by Wittgenstein, had taken up what came to be called ordinary language philosophy. Philosophers of this persuasion focused on the role of words in the lives of ordinary speakers, hoping thereby to escape longstanding philosophical muddles. These muddles resulted, they thought, from a natural tendency, when pursuing philosophical theses, to be misled by the grammatical form of sentences in which those questions were posed. (A classic illustration might be Heidegger's supposition that 'nothing' must designate something, though a very peculiar something.)

Today, it is difficult to find much unanimity in the ranks of analytic philosophers. There is, perhaps, an implicit respect for argument and clarity, an evolving though informal agreement as to what problems are and are not tractable, and a conviction that philosophy is in some sense continuous with science. The practice of analytic philosophers to address one another rather than the broader public has led some to decry philosophy's "professionalization" and to call for a return to a pluralistic, community-oriented style of philosophizing. Analytic philosophers respond by pointing out that analytic techniques and standards have been well represented in the history of philosophy.

See also CONTINENTAL PHILOSOPHY, ORDINARY LANGUAGE PHILOSOPHY, PLURALISM, VIENNA CIRCLE. J.F.H.

analytic-synthetic distinction, the distinction, made famous by Kant, according to which an affirmative subject-predicate statement (proposition, judgment) is called *analytic* if the predicate concept is contained in the subject concept, and synthetic otherwise. The statement 'All red roses are red' is analytic, since the concept *red* is contained in the concept *red roses*. 'All roses are red' is synthetic, since the concept *red* is not contained in the concept *roses*. The denial of an affirmative analytic subject-predicate statement entails a contradiction; e.g., 'Not all red roses are red' entails 'Some roses are both red and not red'.

One concept may be contained in another, in Kant's sense, even though the terms used to express them are not related as part to whole. Since 'biped' means 'two-footed animal', the concept *two-footed* is contained in the concept *biped*. It is accordingly analytic that all bipeds are two-footed. The same analytic statement is expressed by the synonymous sentences 'All bipeds are two-footed' and 'All two-footed animals are two-footed'. Unlike statements, sentences cannot be classified as analytic or synthetic except relative to an interpretation. Witness 'All Russian teachers are Russian', which in one sense expresses the analytic statement 'All teachers that are Russian are Russian', and in another the synthetic statement 'All teachers of Russian are Russian'.

Kant's innovation over Leibniz and Hume lay in separating the logico-semantic analytic-synthetic distinction from the epistemological a priori-a posteriori distinction and from the modal-metaphysical necessary-contingent distinction. It seems evident that any analytic statement is a priori (knowable without empirical evidence) and necessary (incapable of falsity). The converse is highly controversial. Kant and his rationalist followers maintain that some a priori and necessary statements are synthetic, citing examples from logic ('Contradictions are impossible', 'The identity relation is transitive'), mathematics ('The sum of 7 and 5 is 12', 'The straight line between two points is the shortest'), and metaphysics ('Every event is caused'). Empiricists like J. S. Mill, Carnap, Ayer, and C. I. Lewis argue that such examples are either synthetic a posteriori or analytic a priori.

Philosophers since Kant have tried to clarify the analytic-synthetic distinction, and generalize it to all statements. On one definition, a sentence is analytic (on a given interpretation) provided it is "true solely in virtue of the meaning or definition of its terms." The truth of any sentence depends in part on the meanings of its terms. 'All emeralds are green' would be false, e.g., if 'emerald' meant 'ruby'. What makes the sentence synthetic, it is claimed, is that its truth also depends on the properties of emeralds, namely, their being green. But the same holds for analytic sentences: the truth of 'All red roses are red' depends on the properties of red roses, namely, their being red. Neither is true solely in virtue of meaning.

A more adequate generalization defines an analytic statement as a formal logical truth: one "true in virtue of its logical form," so that all statements with the same form are true. In terms of sentences under an interpretation, an analytic truth is an explicit logical truth (one whose surface structure represents its logical form) or one that becomes an explicit logical truth when synonyms are substituted. The negative statement that tomorrow is not both Sunday and not Sunday is analytic by this definition, because all statements of the form $\int(p \,\&\, {\sim}p)$ are true. Kant's definition is obtained as a special case by stipulating that the predicate of an affirmative subject-predicate statement is contained in the subject provided the statement is logically true.

On a third generalization, 'analytic' denotes any statement whose denial entails a contradiction. Subject S contains predicate P provided being S entails being P. Whether this is broader or narrower than the second generalization depends on how 'entailment', 'logical form', and 'contradiction' are defined. On some construals, 'Red is a color' counts as analytic on the third generalization (its denial entails 'Something is and is not a color') but not on the second ('red' and 'colored' are logically unstructured), while the rulings are reversed for a counterfactual conditional like 'If this were a red rose it would be red'.

Following Quine, many have denied any distinction between analytic and synthetic statements. Some arguments presume the problematic "true by meaning" definition. Others are that: (1) the distinction cannot be defined without using related notions like 'meaning', 'concept', and 'statement', which are neither extensional nor definable in terms of behavior; (2) some statements (like 'All cats are animals') are hard to classify as analytic or synthetic; and (3) no statement (allegedly) is immune to rejection in the face of new empirical evidence. If these arguments were sound, however, the distinction between logical truths and others would seem equally dubious, a conclusion seldom embraced.

Some describe a priori truths, both synthetic and analytic, as conceptual truths, on the theory that they are all true in virtue of the nature of the concepts they contain. Conceptual truths are said to have no "factual content" because they are about concepts rather than things in the actual world. While it is natural to classify a priori truths together, the proffered theory is questionable. As indicated above, all truths hold in part because of the identity of their concepts, and in part because of the nature of the objects they are about. It is a fact that all emeralds are emeralds, and this proposition is about emeralds, not concepts.

anamnesis. See FORM, PLATO.

ānanda. See SAT/CHIT/ĀNANDA.

ananke (Greek, 'necessity'), the term used by early Greek philosophers for a constraining or moving natural force. In Parmenides (frg. 8, line 30) *ananke* encompasses reality in limiting bonds; according to Diogenes Laertius, Democritus calls the vortex that generates the cosmos *ananke;* Plato (*Timaeus* 47e *ff.*) refers to *ananke* as the irrational element in nature, which reason orders in creating the physical world. As used by Aristotle (*Metaphysics* V.5), the basic meaning of 'necessary' is 'that which cannot be otherwise', a sense that includes logical necessity. He also distinguishes (*Physics* II.9) between simple and hypothetical necessity (conditions that must hold *if* something is to occur). **See also** ARISTOTLE, PARMENIDES. W.J.P.

anaphor. See ANAPHORA.

anaphora, a device of reference or cross-reference in which a term (called an *anaphor*), typically a pronoun, has its semantic properties determined by a term or noun phrase (called the anaphor's *antecedent*) that occurs earlier. Sometimes the antecedent is a proper name or other independently referring expression, as in 'Jill went up the hill and then *she* came down again'. In such cases, the anaphor refers to the same object as its antecedent. In other cases, the anaphor seems to function as a variable bound by an antecedent quantifier, as in 'If any miner bought a donkey, *he* is penniless'. But anaphora is puzzling because not every example falls neatly into one of these two groups. Thus, in 'John owns some sheep and Harry vaccinates *them*' (an example due to Gareth Evans) the anaphor is arguably not bound by its antecedent 'some sheep'. And in 'Every miner who owns a donkey beats *it*' (a famous type of case discovered by Geach), the anaphor is arguably bound neither by 'a donkey' nor by a uniquely referring expression. **See also** QUANTIFICATION, THEORY OF DESCRIPTIONS. M.M.

anarchism. See KROPOTKIN, POLITICAL PHILOSOPHY.

anattāvāda, the Buddhist doctrine of no-soul, attributed to the Buddha (sixth century B.C.). The Buddha's idea of dependent origination (*pratītyasamutpāda*) leads to a process ontology of change where nothing is absolute, permanent, or substantive. Accordingly, the Buddha taught that a person's self consists of a bundle of fleeting impressions, analyzed into five groups (*skandhas*), rather than a substantive entity called the "soul." The Buddha's method of introspection to find out whether we can be aware of a soul-like substance inside us is remarkably similar to David Hume's. The Hindu philosophical schools objected to *anattāvāda* because they thought it could not satisfactorily explain such issues as personal identity, moral responsibility and karma, and rebirth. D.K.C.

Anaxagoras (c.500–428 B.C.), Greek philosopher who was the first of the pre-Socratics to teach in Athens (c.480–450), where he influenced leading intellectuals such as Pericles and Euripides. He left Athens when he was prosecuted for impiety. Writing in response to Parmenides, he elaborated a theory of matter according to which nothing comes into being or perishes. The ultimate realities are stuffs such as water and earth, flesh and bone, but so are contraries such as hot and cold, likewise treated as stuffs. Every phenomenal substance has a portion of every elemental stuff, and there are no minimal parts of anything, but matter takes on the phenomenal properties of whatever predominates in the mixture. Anaxagoras posits an indefinite number of elemental stuffs, in contrast to his contemporary Empedocles, who requires only four elements; but Anaxagoras follows Parmenides more rigorously, allowing no properties or substances to emerge that were not already present in the cosmos as its constituents. Thus there is no ultimate gap between appearance and reality: everything we perceive is real. In Anaxagoras's cosmogony, an initial chaos of complete mixture gives way to an ordered world when *noûs* (mind) begins a vortex motion that separates cosmic masses of ether (the bright upper air), air, water, and earth. Mind is finer than the stuffs and is found in living things, but it does not mix with stuffs. Anaxagoras's theory of mind provides the first hint of a mind-matter dualism. Plato and Aristotle thought his assigning a cosmic role to mind made him sound like "a sober man" among his contemporaries, but they were disappointed that he did not exploit his idea to provide teleological explanations of natural phenomena. **See also** PRE-SOCRATICS. D.W.G.

Anaximander (c.612–545 B.C.), Greek philosopher and cosmologist, reputedly the student and successor of Thales in the Milesian school. He described the cosmos as originating from *apeiron* (the boundless) by a process of separating off; a disk-shaped earth was formed, surrounded by concentric heavenly rings of fire enclosed in air. At "breathing holes" in the air we see jets of fire, which are the stars, moon, and sun. The earth stays in place because there is no reason for it to tend one way or another. The seasons arise from alternating periods where hot and dry or wet and cold powers predominate, governed by a temporal process (figuratively portrayed as the judgment of Time). Anaximander drew a map of the world and explained winds, rain, and lightning by naturalistic hypotheses. He also described the emergence of life in a way that prefigures the theory of evolution. Anaximander's interest in cosmology and cosmogony and his brilliant conjectures set the major questions for later pre-Socratics. **See also** APEIRON, MILESIANS. D.W.G.

Anaximenes of Miletus (fl. c.545 B.C.), Greek philosopher, a pre-Socratic who, following in the tradition of the Milesians Thales and Anaximander, speculated about cosmology and meteorology. The source (*archē*) of the cosmos is air (*aēr*, originally mist), which by a process of rarefaction becomes fire, and by a process of condensation becomes wind, clouds, water, earth, and stones. Air is divine and causes life. The earth is flat and rides on a cushion of air, while a heavenly firmament revolves about it like a felt cap. Anaximenes also explained meteorological phenomena and earthquakes. Although less innovative than his predecessor Anaximander, he made progress in naturalistic explanations by appealing to a quantitative process of rarefaction and condensation rather than to mythical processes involving quasi-personal agents. D.W.G.

ancestral (of a given relation *R*), the relation (also called the transitive closure of *R*) that relates one given individual to a second if and only if the first can be "reached" from the second by repeated "applications" of the given relation *R*. The ancestor relation is the *ancestral* of the parent relation since one person is an ancestor of a second if the first is a parent of the second or the first is a parent of a parent of the second or the first is a parent of a parent of a parent of the second, and so on. Frege discovered a simple method of giving a materially adequate and formally correct definition of the ancestral of a given relation in terms of the relation itself (plus logical concepts). This method is informally illustrated as follows: in order for one person *A* to be an ancestor of a second person *B* it is necessary and sufficient for *A* to have every property that belongs to every parent of *B* and that belongs to every parent of any person to whom it belongs. This and other similar methods made possible the reduction of all numerical concepts to those of zero and successor, which Frege then attempted to reduce to concepts of pure logic. Frege's definition of the ancestral has become a paradigm in modern analytic philosophy as well as a historical benchmark of the watershed between traditional logic and modern logic. It demonstrates the exactness of modern logical analysis and, in comparison, the narrowness of traditional logic. **See also** FREGE, LOGICISM, RELATION. J.Cor.

ancient atomism, the theory, originated by Leucippus and elaborated by Democritus, that the ultimate realities are atoms and the void. The theory was later used by Epicurus as the foundation for a philosophy stressing ethical concerns, Epicureanism. **See also** DEMOCRITUS, EPICUREANISM. D.W.G.

Andronicus of Rhodes (first century B.C.), Greek philosopher, a leading member of the Lyceum, who was largely responsible for establishing the canon of Aristotle's works still read today. He also edited the works of Theophrastus. At the time, Aristotle was known primarily for his philosophical dialogues, only fragments of which now survive; his more methodical treatises had stopped circulating soon after his death. By producing the first systematic edition of Aristotle's corpus, Andronicus revived study of the treatises, and the resulting critical debates dramatically affected the course of philosophy. Little is recorded about Andronicus's labors; but besides editing the texts and discussing titles, arrangement, and authenticity, he sought to explicate and assess Aristotle's thought. In so doing, he and his colleagues initiated the exegetical tradition of Aristotelian commentaries. Nothing he wrote survives; a summary account of emotions formerly ascribed to him is spurious. **See also** ARISTOTLE, COMMENTARIES ON ARISTOTLE, LYCEUM. V.C. & S.A.W.

Anesidemus. See HELLENISTIC PHILOSOPHY, SKEPTICS.

Angst, German term for a special form of anxiety, an emotion seen by existentialists as both constituting and revealing the human condition. *Angst* plays a key role in the writings of Heidegger, whose concept is closely related to Kierkegaard's *angest* and Sartre's *angoisse*. The concept is first treated in this distinctive way in Kierkegaard's *The Concept of Anxiety* (1844), where anxiety is described as "the dizziness of freedom." Anxiety here represents freedom's self-awareness; it is the psychological precondition for the individual's attempt to become autonomous, a possibility that is seen as both alluring and disturbing. **See also** HEIDEGGER, KIERKEGAARD, SARTRE. Annas, Julia (b.1946), British American philosopher and classical scholar; founding editor of *Oxford Studies in Ancient Philosophy*; and a scholar of ancient philosophy with interests in ethics, psychology, metaphysics, and epistemology. Her *Introduction to Plato's "Republic"* (1981) presents that work as a revolutionary essay on the objective truth of ethical values; in *Platonic Ethics Old and New* (1999) she shows that Plato's successors understood the *Republic* as more ethical than political. Her translations with Jonathan Barnes of skeptical works have made them accessible to a wide audience (*The Modes of Scepticism*, 1990; *Sextus Empiricus: Outlines of Scepticism*, 1994). Annas is best known for her work on virtue ethics – the ethics of character – both ancient and modern. Her best-known book on ancient ethics is *The Morality of Happiness* (1993), in which she situates virtue in an account of happiness as the aim of a human life. In 2011 she published an original book expounding and defending virtue ethics, *Intelligent Virtue*, in which she develops an account of virtue as analogous to a practical skill. After teaching at St. Hugh's College, Oxford, from 1970 to 1986, she moved in 1986 to the University of Arizona, where she has been Regents Professor of Philosophy since 1995. P.Wo.

Anniceraioi. See ANNICERIS.

Anniceris (fl. c.320–280 B.C.), Greek philosopher. A pupil of Antipater, he established a separate branch of the Cyrenaic school known as the *Anniceraioi*. He subscribed to typical Cyrenaichedonism, arguing that the end of each action should be one's own pleasure, since we can know nothing of others' experiences. He tempered the implications of hedonism with the claim that a wise man attaches weight to respect for parents, patriotism, gratitude, and friendship, perhaps influencing Epicurus in this regard. Anniceris also played down the Cyrenaic stress on the intellect's role in hedonistic practical rationality, taking the Aristotelian view that cultivation of the right habits is indispensable. **See also** CYRENAICS. Anscombe, G(ertrude) E(lizabeth) M(argaret) (1919–2001), English philosopher who held positions at Oxford and Cambridge, best known for her work in the philosophy of mind and for her editions and translations of Wittgenstein's later writings. Anscombe studied philosophy with Wittgenstein and became closely associated with him, writing *An Introduction to Wittgenstein's "Tractatus"* (1959). She was married to Peter Geach.

Anscombe's first major work was *Intention* (1957). She argues that the concept of intention is central to our understanding of ourselves as rational agents. The basic case is that of the intentions with which we act. These are identified by the reasons we give in answer to why-questions concerning our actions. Such reasons usually form a hierarchy that constitutes a practical syllogism of which action itself is the conclusion. Hence our intentions are a form of active practical knowledge that normally leads to action. Anscombe compares the direction of fit of this kind of knowledge with a shopping list's relation to one's purchases, and contrasts it with the direction of fit characteristic of a list of these purchases drawn up by an observer of the shopper. She maintains that the deep mistake of modern (i.e., postmedieval) philosophy has been to think that all knowledge is of this latter, observational, type. This conception of active knowledge expressed through an agent's intentions conflicts with the passive conception of rationality characteristic of Hume and his followers, and she develops this challenge in papers critical of the is-ought distinction of Hume and his modern successors. In a famous paper, "Modern Moral Philosophy" (1958), she also argues that ought-statements make sense only in the context of a moral theology that grounds morality in divine commands. Since our culture rejects this theology, it is no surprise that "modern moral philosophers" cannot find much sense in them. We should therefore abandon them and return to the older conceptions of practical rationality and virtue. These conceptions, and the associated conception of natural law, provide the background to an uncompromising defense of traditional Catholic morality concerning sexuality, war, and the importance of the distinction between intention and foresight.

Anscombe was never afraid of unpopular positions – philosophical and ethical. Her three-volume *Collected Papers* (1981) includes a defense of singular causation, an attack on the very idea of a subject of thought, and a critique of pacifism. She was one of the most original and distinctive English philosophers of her generation.

T.R.B.

Anselm, Saint, called Anselm of Canterbury (1033–1109), Italian-born English philosophical theologian. A Benedictine monk and the second Norman archbishop of Canterbury, he is best known for his distinctive method – *fides quaerens intellectum;* his "ontological" argument for the existence of God in his treatise *Proslogion;* and his classic formulation of the satisfaction theory of the Atonement in the *Cur Deus homo*. Like Augustine before him, Anselm is a Christian Platonist in metaphysics. He argues that the most accessible proofs of the existence of God are through value theory: in his treatise *Monologion*, he deploys a cosmological argument, showing the existence of a source of all goods, which is the Good per se and hence supremely good; that same thing exists per se and is the Supreme Being. In the *Proslogion*, Anselm begins with his conception of a being a greater than which cannot be conceived, and mounts his ontological argument that a being a greater than which cannot be conceived exists in the intellect, because even the fool understands the phrase when he hears it; but if it existed in the intellect alone, a greater could be conceived that existed in reality. This supremely valuable object is essentially whatever it is – other things being equal – that is better to be than not to be, and hence living, wise, powerful, true, just, blessed, immaterial, immutable, and eternal per se; even the paradigm of sensory goods – Beauty, Harmony, Sweetness, and Pleasant Texture, in its own ineffable manner. Nevertheless, God is supremely simple, not compounded of a plurality of excellences, but "*omne et unum, totum et solum bonum*," a being a more delectable than which cannot be conceived.

Everything other than God has its being and its well-being through God as efficient cause. Moreover, God is the paradigm of all created natures, the latter ranking as better to the extent that they more perfectly resemble God. Thus, it is better to be human than to be horse, to be horse than to be wood, even though in comparison with God everything else is "almost nothing." For every created nature, there is a that-for-which-it-is-made (*ad quod factum est*). On the one hand, Anselm thinks of such teleology as part of the internal structure of the natures themselves: a creature of type *F* is a *true F* only insofar as it is/does/exemplifies that for which *F*'s were made; a defective *F*, to the extent that it does not. On the other hand, for Anselm, the *telos* of a created nature is that-for-which-*God*-made-it. Because God is personal and acts through reason and will, Anselm infers that prior (in the order of explanation) to creation, there was, in the reason of the maker, an exemplar, form, likeness, or rule of what he was going to make. In *De veritate* Anselm maintains that such teleology gives rise to obligation: since creatures *owe* their being and well-being to God as their cause, so they *owe* their being and well-being to God in the sense of having an obligation to praise him by being the best beings they can. Since every creature is of some nature or other, each can be its best by being that-for-which-God-made-it. Abstracting from impediments, non-rational natures fulfill this obligation and "act rightly" by natural necessity; rational creatures, when they exercise their powers of reason and will to fulfill God's purpose in creating them. Thus, the goodness of a creature (how good a being it is) is a function of twin factors: its natural *telos* (i.e., what sort of imitation of divine nature it aims for) and its rightness (in exercising its natural powers to fulfill its *telos*). By contrast, God as absolutely independent owes no one anything and so has no obligations to creatures.

In *De casu diaboli*, Anselm underlines the optimism of his ontology, reasoning that since the Supreme Good and the Supreme Being are identical, every being is good and every good a being. Two further conclusions follow. First, evil is a privation of being, the absence of good in something that properly ought to have it (e.g., blindness in normally sighted animals, injustice in humans or angels). Second, since all genuine powers are given to enable a being to fulfill its natural *telos* and so to be the best being it can, all genuine (metaphysically basic) powers are optimific and essentially aim at goods, so that evils are merely incidental side effects of their operation, involving some lack of coordination among powers or between their exercise and the surrounding context. Thus, divine omnipotence does not, properly speaking, include corruptibility, passibility, or the ability to lie, because the latter are defects and/or powers in other things whose exercise obstructs the flourishing of the corruptible, passible, or potential liar.

Anselm's distinctive action theory begins teleologically with the observation that humans and angels were made for a happy immortality enjoying God, and to that end were given the powers of reason to make accurate value assessments and will to love accordingly. Anselm regards freedom and imputability of choice as essential and permanent features of all rational beings. But freedom cannot be defined as a power for opposites (the power to sin and the power not to sin), both because neither God nor the good angels have any power to sin, and because sin is an evil at which no metaphysically basic power can aim. Rather, freedom is the power to preserve justice for its own sake. Choices and actions are *imputable* to an agent only if they are spontaneous, from the agent itself. Creatures cannot act spontaneously by the necessity of their natures, because they do not have their natures from themselves but receive them from God. To give them the opportunity to become just of themselves, God furnishes them with two motivational drives toward the good: an affection for the advantageous (*affectio commodi*) or a tendency to will things for the sake of their benefit to the agent itself; and an affection for justice (*affectio justitiae*) or a tendency to will things because of their own intrinsic value. Creatures are able to align these drives (by letting the latter temper the former) or not. The good angels, who preserved justice by not willing some advantage possible for them but forbidden by God for that time, can no longer will more advantage than God wills for them, because he wills their maximum as a reward. By contrast, creatures, who sin by refusing to delay gratification in accordance with God's will, lose both uprightness of will and their affection for justice, and hence the ability to temper their pursuit of advantage or to will the best goods. Justice will never be restored to angels who desert it. But if animality makes human nature weaker, it also opens the possibility of redemption.

Anselm's argument for the necessity of the Incarnation plays out the dialectic of justice and mercy so characteristic of his prayers. He begins with the demands of justice: humans owe it to God to make all of their choices and actions conform to his will; failure to render what was owed insults God's honor and makes the offender liable to make satisfaction; because it is worse to dishonor God than for countless worlds to be destroyed, the satisfaction owed for any small sin is incommensurate with any created good; it would be maximally indecent for God to overlook such a great offense. Such calculations threaten certain ruin for the sinner, because God alone can do/be immeasurably deserving, and depriving the creature of its honor (through the eternal frustration of its *telos*) seems the only way to balance the scales. Yet justice also forbids that God's purposes be thwarted through created resistance, and it was *divine mercy* that made humans for a beatific immortality with him. Likewise, humans come in families by virtue of their biological nature (which angels do not share), and justice allows an offense by one family member to be compensated by another. Assuming that all actual humans are descended from common first parents, Anselm claims that the human race can make satisfaction for sin, if God becomes human and renders to God what Adam's family owes.

When Anselm insists that humans were made for beatific intimacy with God and therefore are obliged to strive into God with all of their powers, he emphatically includes reason or intellect along with emotion and will. God, the controlling subject matter, is in part permanently inaccessible to us (because of the ontological incommensuration between God and creatures) and our progress is further hampered by the consequences of sin. Our powers will function best, and hence we have a duty to follow right order in their use: by submitting first to the holistic discipline of faith, which will focus our souls and point us in the right direction. Yet it is also a duty not to remain passive in our appreciation of authority, but rather for faith to seek to understand what it has believed. Anselm's works display a dialectical structure, full of questions, objections, and contrasting opinions, designed to stir up the mind. His quartet of teaching dialogues – *De grammatico, De veritate, De libertate arbitrii*, and *De casu diaboli* – as well as his last philosophical treatise, *De concordia*, anticipate the genre of the Scholastic question (*quaestio*) so dominant in the thirteenth and fourteenth centuries. His discussions are likewise remarkable for their attention to modalities and proper-versus-improper linguistic usage.

Antiochus of Ascalon (c.130–c.68 B.C.), Greek philosopher and the last prominent member of the New Academy. He played the major role in ending its two centuries of Skepticism and helped revive interest in doctrines from the Old Academy, as he called Plato, Aristotle, and their associates.

The impulse for this decisive shift came in epistemology, where the Skeptical Academy had long agreed with Stoicism that knowledge requires an infallible "criterion of truth" but disputed the Stoic claim to find this criterion in "cognitive perception." Antiochus's teacher, Philo of Larissa, broke with this tradition and proposed that perception need not be cognitive to qualify as knowledge. Rejecting this concession, Antiochus offered new arguments for the Stoic claim that some perception is cognitive, and hence knowledge. He also proposed a similar accommodation in ethics, where he agreed with the Stoics that virtue alone is sufficient for happiness but insisted with Aristotle that virtue is not the only good. These and similar attempts to mediate fundamental disputes have led some to label Antiochus an eclectic or syncretist; but some of his proposals, especially his appeal to the Old Academy, set the stage for Middle Platonism, which also sought to reconcile Plato and Aristotle. No works by Antiochus survive, but his students included many eminent Romans, most notably Cicero, who summarizes Antiochus's epistemology in the *Academica*, his critique of Stoic ethics in *De finibus* IV, and his purportedly Aristotelian ethics in *De finibus* V.

anti-realism, rejection, in one or another form or area of inquiry, of realism, the view that there are knowable mind-independent facts, objects, or properties. Metaphysical realists make the general claim that there is a world of mind-independent objects. Realists in particular areas make more specific or limited claims. Thus moral realists hold that there are mind-independent moral properties, mathematical realists that there are mind-independent mathematical facts, scientific realists that scientific inquiry reveals the existence of previously unknown and unobservable mind-independent entities and properties. Anti-realists deny either that facts of the relevant sort are mind-independent or that knowledge of such facts is possible.

Berkeley's subjective idealism, which claims that the world consists only of minds and their contents, is a metaphysical anti-realism. Constructivist anti-realists, on the other hand, deny that the world consists only of mental phenomena, but claim that it is constituted by, or constructed from, our evidence or beliefs. Many philosophers find constructivism implausible or even incoherent as a metaphysical doctrine, but much more plausible when restricted to a particular domain, such as ethics or mathematics.

Debates between realists and anti-realists have been particularly intense in philosophy of science. Scientific realism has been rejected both by constructivists, such as Kuhn, who hold that scientific facts are constructed by the scientific community, and by empiricists who hold that knowledge is limited to what can be observed. A sophisticated version of the latter doctrine is Bas van Fraassen's constructive empiricism, which allows scientists free rein in constructing scientific models, but claims that evidence for such models confirms only their observable implications.

apeiron, Greek term meaning 'the boundless' or 'the unlimited', which evolved to signify 'the infinite'. Anaximander introduced the term to philosophy by saying that the source of all things was *apeiron*. There is some disagreement about whether he meant by this the spatially unbounded, the temporally unbounded, or the qualitatively indeterminate. It seems likely that he intended the term to convey the first meaning, but the other two senses also happen to apply to the spatially unbounded. After Anaximander, Anaximenes declared as his first principle that air is boundless, and Xenophanes made his flat earth extend downward without bounds, and probably outward horizontally without limit as well. Rejecting the tradition of boundless principles, Parmenides argued that "what-is" must be held within determinate boundaries. But his follower Melissus again argued that what-is must be boundless – in both time and space – for it can have no beginning or end. Another follower of Parmenides, Zeno of Elea, argued that if there are many substances, antinomies arise, including the consequences that substances are both limited and unlimited (*apeira*) in number, and that they are so small as not to have size and so large as to be unlimited in size. Rejecting monism, Anaxagoras argued for an indefinite number of elements that are each unlimited in size, and the Pythagorean Philolaus made limiters (*perainonta*) and unlimiteds (*apeira*) the principles from which all things are composed. The atomists Leucippus and Democritus conceived of a boundless universe, partly full (of an infinite number of atoms) and partly void; and in the universe are countless (*apeiroi*) worlds. Finally Aristotle arrived at an abstract understanding of the *apeiron* as "the infinite," claiming to settle paradoxes about the boundless by allowing for real quantities to be infinitely divisible potentially, but not actually (*Physics* III.4–8). The development of the notion of the *apeiron* shows how Greek philosophers evolved ever more abstract philosophical ideas from relatively concrete conceptions. **See also** ARISTOTLE, PRE-SOCRATICS. D.W.G.

Apel, Karl Otto (b.1922), German philosopher working in the Kantian tradition and known chiefly for attempting to transcendentally found universal morality on the necessary presuppositions underlying communication ("A Priori of the Communication Community and the Foundations of Ethics," 1972; and *The Response of Discourse Ethics*, 1994). This endeavor merged with the development of discourse ethics by his younger colleague at the University of Frankfurt, Jürgen Habermas, who became the leading second-generation exponent of the Frankfurt School tradition of critical social theory. The philosophical trajectories of these thinkers overlap in other important ways. Early in their careers, both wrote dissertations under Erich Rothacker; both introduced the German philosophical community to the semiotic theory of the American pragmatist Peirce; both fused the hermeneutical philosophy of Dilthey to the linguistic philosophy of Wittgenstein; and both undertook a transcendental grounding of the humanities and sciences in terms of a theory of knowledge-constitutive interests. These pioneering achievements were summarized in Apel's two-volume *Towards a Transformation of Philosophy* (1973). Despite such overlaps, Apel has sought to distinguish his transcendental linguistic philosophy (transcendental semiotics) from Habermas's more social-scientific variant (universal pragmatics), and his unified theory of morality and law from Habermas's less reductive theory. **See also** FRANKFURT SCHOOL, HABERMAS. D.I.

apellatio. See PROPRIETATES TERMINORUM.

apocatastasis (from Greek, 'reestablishment'), the restoration of all souls, including Satan's and his minions', in the kingdom of God. God's goodness will triumph over evil, and through a process of spiritual education souls will be brought to repentance and made fit for divine life. The theory originates with Origen but was also held by Gregory of Nyssa. In modern times F. D. Maurice (1805–72) and Karl Barth (1886–1968) held this position. **See also** GREGORY OF NYSSA, ORIGEN. L.P.P.

apodictic. See HUSSERL, KANT.

apodosis. See COUNTERFACTUALS.

apophantic. See HUSSERL.

apophatic (from the Greek words for 'denial' and 'to speak'), a term often used in reference to philosophers who deny (or views which deny) that God or the sacred can be understood or described using positive attributes; rather, only negations are permissible in describing God (God is not corporeal, not ignorant, not temporal). Ostensibly positive attributions are permissible only if they are disguised negations ('God is all-powerful' becomes 'God does not lack any great-making power'). Apophatic philosophers argue that countenancing positive attributes of God entails that God is comparable to us (e.g., more powerful than we) and thus fails to recognize God's incomparable (*sui generis*) being, as established through revelation or natural theology (Maimonides supported apophatic philosophy on the basis of cosmological arguments). There are apophatic strands in Judaism, Christianity, Islam, and some forms of Hinduism. The author of *On the Divine Names*, known as Denys the Areopagite (also referred to as Pseudo-Dionysius, late fifth–early sixth century), is highly influential in the Western apophatic tradition. **See also** PHILOSOPHY OF RELIGION. C.C.T.

aporetic. See *APORIA*.

aporia (plural: *aporiai*), Greek term meaning 'puzzle', 'question for discussion', 'state of perplexity'. The *aporetic method* – the raising of puzzles without offering solutions – is typical of the elenchus in the early Socratic dialogues of Plato. These consist in the testing of definitions and often end with an *aporia*, e.g. that piety is both what is and what is not loved by the gods. Compare the paradoxes of Zeno, e.g. that motion is both possible and impossible.

In Aristotle's dialectic, the resolution of *aporiai* discovered in the views on a subject is an important source of philosophical understanding. The beliefs that one should love oneself most of all and that self-love is shameful, e.g., can be resolved with the right understanding of 'self'. The possibility of argument for two inconsistent positions was an important factor in the development of Skepticism. In modern philosophy, the antinomies that Kant claimed reason would arrive at in attempting to prove the existence of objects corresponding to transcendental ideas may be seen as *aporiai*.

apperception. See KANT.

Appiah, Kwame Anthony (b.1954), British-Ghanaian-American philosopher and cultural theorist whose wide-ranging work encompasses ethics, philosophy of language, political theory, philosophy of mind, literary criticism, and African and African American intellectual history. Appiah earned his Ph.D. from Cambridge University in 1982 and has taught at Yale, Cornell, Duke, and Harvard and, since 2002, at Princeton.

Appiah's early writings (*Assertion and Conditionals*, 1985; *For Truth in Semantics*, 1986) defend a realist theory of meaning by offering a probabilistic semantics for assertions. He is best known, however, for his writings on the race concept, social identities, and cosmopolitanism. Through a critique of W. E. B. Du Bois's Pan-Africanism, Appiah initiated a philosophical debate over the ontological status of "races." Using his skills as a philosopher of language and his knowledge of contemporary biology, he argues that the biological concept of race is neither empirically adequate nor analytically cogent, and that it serves no useful purpose and should therefore be abandoned (*In My Father's House*, 1992; *Color Conscious*, 1996). While he insists that we should not believe in the existence of races, he argues that there are individuals who share "racial identities," modes of identification and common vulnerabilities rooted in the illusion of inherent racial difference. Appiah offers a liberal defense of the value of various social identities, arguing that while they can be irrational and constrain individual freedom and so should sometimes be reformed, they are also indispensable for individuality and sustain vital attachments (*The Ethics of Identity*, 2005). He also defends "partial cosmopolitanism," a moral ideal of global citizenship that eschews nationalism but is compatible with civic patriotism (*Cosmopolitanism: Ethics in a World of Strangers*, 2006). Appiah argues that we should respect legitimate differences in modes of living but that these local allegiances should be joined with an abiding concern for, and a willingness to engage in dialogue with, distant others with whom we have much in common.

application (of a function). See COMBINATORY LOGIC.

applied ethics, the domain of ethics that includes professional ethics, such as business ethics, engineering ethics, and medical ethics, as well as practical ethics, such as environmental ethics, which is applied and thus practical as opposed to theoretical, but not focused on any one discipline. One of the major disputes among those who work in applied ethics is whether or not there is a general and universal account of morality applicable both to the ethical issues in the professions and to various practical problems. Some philosophers believe that each of the professions or each field of activity develops an ethical code for itself and that there need be no close relationship between, e.g., business ethics, medical ethics, and environmental ethics. Others hold that the same moral system applies to all professions and fields. They claim that the appearance of different moral systems is simply due to certain problems being more salient for some professions and fields than for others.

The former position accepts the consequence that the ethical codes of different professions might conflict with one another, so that a physician in business might find that business ethics would require one action but medical ethics another. Engineers who have been promoted to management positions sometimes express concern over the tension between what they perceive to be their responsibility as engineers and their responsibility as managers in a business. Many lawyers seem to hold that there is similar tension between what common morality requires and what they must do as lawyers. Those who accept a universal morality hold that these tensions are all resolvable because there is only one common morality.

Underlying both positions is the pervasive but false view of common morality as providing a unique right answer to every moral problem. Those who hold that each profession or field has its own moral code do not realize that common morality allows for conflicts of duties. Most of those who put forward moral theories, e.g., utilitarians, Kantians, and contractarians, attempt to generate a universal moral system that solves all moral problems. This creates a situation that leads many in applied ethics to dismiss theoretical ethics as irrelevant to their concerns. An alternative view of a moral theory is to think of it on the model of a scientific theory, primarily concerned to describe common morality rather than generate a new improved version. On this model, it is clear that although morality rules out many alternatives as unacceptable, it does not provide unique right answers to every controversial moral question.

On this model, different fields and different professions may interpret the common moral system in somewhat different ways. For example, although deception is always immoral if not justified, what counts as deception is not the same in all professions. Not informing a patient of an alternative treatment counts as deceptive for a physician, but not telling a customer of an alternative to what she is about to buy does not count as deceptive for a salesperson. The professions also have considerable input into what special duties are incurred by becoming a member. Applied ethics is thus not the mechanical application of a common morality to a particular profession or field, but an independent discipline that clarifies and analyzes the practices in a field or profession so that common morality can be applied.

a priori, prior to or independent of experience; contrasted with 'a posteriori' (empirical). These two terms are primarily used to mark a distinction between (1) two modes of epistemic justification, together with derivative distinctions between (2) kinds of propositions, (3) kinds of knowledge, and (4) kinds of argument. They are also used to indicate a distinction between (5) two ways in which a concept or idea may be acquired.

(1) A belief or claim is said to be justified a priori if its epistemic justification, the reason or warrant for thinking it to be true, does not depend at all on sensory or introspective or other sorts of *experience;* whereas if its justification does depend at least in part on such experience, it is said to be justified a posteriori or empirically.

This specific distinction concerns only the justification of the belief, and not at all how the constituent concepts are acquired; thus it is no objection to a claim of a priori justificatory status for a particular belief that experience is required for the acquisition of some of the constituent concepts. The relevant notion of experience includes sensory and introspective experience, as well as such things as kinesthetic experience. Equally clearly, to construe experience in the broadest possible sense of, roughly, a conscious undergoing of any sort would be to destroy the point of the distinction, since even a priori justification presumably involves some sort of conscious process of awareness. The construal that is perhaps most faithful to the traditional usage is that which construes experience as any sort of cognitive input that derives, presumably causally, from features of the actual world that may not hold in other possible worlds. Thus, e.g., such things as clairvoyance or telepathy, if they were to exist, would count as forms of experience and any knowledge resulting therefrom as a posteriori; but the intuitive apprehension of properties or numbers or other sorts of abstract entities that are the same in all possible worlds would not.

Understood in this way, the concept of a priori justification is an essentially negative concept, specifying as it does what the justification of the belief does *not* depend on, but saying nothing about what it does depend on. Historically, the main positive conception was that offered by proponents of rationalism (such as Plato, Descartes, Spinoza, and Leibniz), according to which a priori justification derives from the intuitive apprehension of necessary facts pertaining to universals and other abstract entities. (Although Kant is often regarded as a rationalist, his restriction of substantive a priori knowledge to the world of appearances represents a major departure from the main rationalist tradition.) In contrast, proponents of traditional empiricism, if they do not repudiate the concept of a priori justification altogether (as does Quine), typically attempt to account for such justification by appeal to linguistic or conceptual conventions. The most standard formulation of this empiricist view (a development of the view of Hume that all a priori knowledge pertains to "relations of ideas") is the claim (typical of logical positivism) that all a priori knowable claims or propositions are analytic. (A rationalist would claim in opposition that at least some a priori claims or propositions are synthetic.)

(2) A proposition that is the content of an a priori justified belief is often referred to as an a priori proposition (or an a priori truth). This usage is also often extended to include any proposition that is capable of being the content of such a belief, whether it actually has this status or not.

(3) If, in addition to being justified a priori or a posteriori, a belief is also true and satisfies whatever further conditions may be required for it to constitute knowledge, that knowledge is derivatively characterized as a priori or a posteriori (empirical), respectively. (Though a priori justification is often regarded as by itself guaranteeing truth, this should be regarded as a further substantive thesis, not as part of the very concept of a priori justification.) Examples of knowledge that have been classically regarded as a priori in this sense are mathematical knowledge, knowledge of logical truths, and knowledge of necessary entailments and exclusions of commonsense concepts ('Nothing can be red and green all over at the same time', 'If *A* is later than *B* and *B* is later than *C*, then *A* is later than *C*'); but many claims of metaphysics, ethics, and even theology have also been considered to have this status.

(4) A deductively valid argument that also satisfies the further condition that each of the premises (or sometimes one or more particularly central premises) are justified a priori is referred to as an a priori argument. This label is also sometimes applied to arguments that are claimed to have this status, even if the correctness of this claim is in question.

(5) In addition to the uses just catalogued that derive from the distinction between modes of justification, the terms 'a priori' and 'a posteriori' are also employed to distinguish two ways in which a concept or idea might be acquired by an individual person. An a posteriori or empirical concept or idea is one that is derived from experience, via a process of abstraction or ostensive definition. In contrast, an a priori concept or idea is one that is not derived from experience in this way and thus presumably does not require any particular experience to be realized (though the explicit realization of such a concept might still require experience as a "trigger"). The main historical account of such concepts, again held mainly by rationalists, construes them as innate, either implanted in the mind by God or, in the more contemporary version of the claim held by Chomsky, Fodor, and others, resulting from evolutionary development. Concepts typically regarded as having this sort of status include those of substance, causation, God, necessity, infinity, and many others. Empiricists, in contrast, typically hold that all concepts are derived from experience.

Aquinas, Saint Thomas (1225–74), Italian philosopher-theologian, the most influential thinker of the medieval period. He produced a powerful philosophical synthesis that combined Aristotelian and Neoplatonic elements within a Christian context in an original and ingenious way.

Life and works. Thomas was born at Aquino castle in Roccasecca, Italy, and took early schooling at the Benedictine Abbey of Monte Cassino. He then studied liberal arts and philosophy at the University of Naples (1239–44) and joined the Dominican order. While planning to go to Paris for further studies as a Dominican, he was detained by his family for about a year. Upon release, he studied with the Dominicans at Paris, perhaps privately, until 1248, when he journeyed to Cologne to work under Albertus Magnus. Thomas's own report (*reportatio*) of Albertus's lectures on the *Divine Names* of Dionysius and his notes on Albertus's lectures on Aristotle's *Ethics* date from this period. In 1252 Thomas returned to Paris to lecture as a bachelor in theology. His resulting commentary on the *Sentences* of Peter Lombard dates from this period, as do two philosophical treatises, *On Being and Essence* (*De ente et essentia*) and *On the Principles of Nature* (*De principiis naturae*).

In 1256 he began lecturing as master of theology at Paris. From this period (1256–59) date a series of scriptural commentaries, the disputations *On Truth* (*De veritate*), Quodlibetal Questions VII–XI, and earlier parts of the *Summa against the Gentiles* (*Summa contra gentiles;* hereafter *SCG*). At different locations in Italy from 1259 to 1269, Thomas continued to write prodigiously, including, among other works, the completion of the *SCG;* a commentary on the *Divine Names;* the disputations *On the Power of God* (*De potentia Dei*) and *On Evil* (*De malo*); and *Summa of Theology* (*Summa theologiae;* hereafter *ST*), Part I. In January 1269, he resumed teaching in Paris as regent master and wrote extensively until returning to Italy in 1272. From this second Parisian regency date the disputations *On the Soul* (*De anima*) and *On Virtues* (*De virtutibus*); continuation of *ST;* Quodlibets I–VI and XII; *On the Unity of the Intellect against the Averroists* (*De unitate intellectus contra Averroistas*); most if not all of his commentaries on Aristotle; a commentary on the *Book of Causes* (*Liber de causis*); and *On the Eternity of the World* (*De aeternitate mundi*). In 1272 Thomas returned to Italy, where he lectured on theology at Naples and continued to write until December 6, 1273, when his scholarly work ceased. He died three months later en route to the Second Council of Lyons.

Doctrine. Aquinas was both a philosopher and a theologian. The greater part of his writings are theological, but there are many strictly philosophical works within his corpus, such as *On Being and Essence, On the Principles of Nature, On the Eternity of the World*, and the commentaries on Aristotle and on the *Book of Causes*. Also important are large sections of strictly philosophical writing incorporated into theological works such as the *SCG, ST*, and various disputations.

Aquinas clearly distinguishes between strictly philosophical investigation and theological investigation. If philosophy is based on the light of natural reason, theology (*sacra doctrina*) presupposes faith in divine revelation. While the natural light of reason is insufficient to discover things that can be made known to human beings only through revelation, e.g. belief in the Trinity, Thomas holds that it is impossible for those things revealed to us by God through faith to be opposed to those we can discover by using human reason. For then one or the other would have to be false; and since both come to us from God, God himself would be the author of falsity, something Thomas rejects as abhorrent. Hence it is appropriate for the theologian to use philosophical reasoning in theologizing. Aquinas also distinguishes between the orders to be followed by the theologian and by the philosopher. In theology one reasons from belief in God and his revelation to the implications of this for created reality. In philosophy one begins with an investigation of created reality insofar as this can be understood by human reason and then seeks to arrive at some knowledge of divine reality viewed as the cause of created reality and the end or goal of one's philosophical inquiry (*SCG* II, c. 4). This means that the order Aquinas follows in his theological *Summae* (*SCG* and *ST*) is not the same as that which he prescribes for the philosopher (cf. Prooemium to Commentary on the *Metaphysics*). Also underlying much of Aquinas's thought is his acceptance of the difference between theoretical or speculative philosophy (including natural philosophy, mathematics, and metaphysics) and practical philosophy.

Being and analogy. For Aquinas the highest part of philosophy is metaphysics, the science of being as being. The subject of this science is not God, but *being*, viewed without restriction to any given kind of being, or simply as being (Prooemium to Commentary on *Metaphysics; In de trinitate*, qu. 5, a. 4). The metaphysician does not enjoy a direct vision of God in this life, but can reason to knowledge of him by moving from created effects to awareness of him as their uncreated cause. God is therefore not the subject of metaphysics, nor is he included in its subject. God can be studied by the metaphysician only indirectly, as the cause of the finite beings that fall under being as being, the subject of the science. In order to account for the human intellect's discovery of being as being, in contrast with being as mobile (studied by natural philosophy) or being as quantified (studied by mathematics), Thomas appeals to a special kind of intellectual operation, a negative judgment, technically named by him "separation." Through this operation one discovers that being, in order to be realized as such, need not be material and changing. Only as a result of this judgment is one justified in studying being as being.

Following Aristotle (and Averroes), Thomas is convinced that the term 'being' is used in various ways and with different meanings. Yet these different usages are not unrelated and do enjoy an underlying unity sufficient for being as being to be the subject of a single science. On the level of finite being Thomas adopts and adapts Aristotle's theory of unity by reference to a first order of being. For Thomas as for Aristotle this unity is guaranteed by the primary referent in our predication of being – substance. Other things are named being only because they are in some way ordered to and dependent on substance, the primary instance of being. Hence being is analogous. Since Thomas's application of analogy to the divine names presupposes the existence of God, we shall first examine his discussion of that issue.

The existence of God and the "five ways." Thomas holds that unaided human reason, i.e. philosophical reason, can demonstrate that God exists, that he is one, etc., by reasoning from effect to cause (*De trinitate*, qu. 2, a. 3; *SCG* I, c. 4). Best known among his many presentations of argumentation for God's existence are the "five ways." Perhaps even more interesting for today's student of his metaphysics is a brief argument developed in one of his first writings, *On Being and Essence* (c. 4). There he wishes to determine how essence is realized in what he terms "separate substances," i.e. the soul, intelligences (angels of the Christian tradition), and the first cause (God).

After criticizing the view that created separate substances are composed of matter and form, Aquinas counters that they are not entirely free from composition. They are composed of a form (or essence) and an act of existing (*esse*). He immediately develops a complex argument: (1) We can think of an essence or *quiddity* without knowing whether or not it actually exists. Therefore in such entities essence and act of existing differ unless (2) there is a thing whose quiddity and act of existing are identical. At best there can be only one such being, he continues, by eliminating multiplication of such an entity either through the addition of some difference or through the reception of its form in different instances of matter. Hence, any such being can only be separate and unreceived *esse*, whereas *esse* in all else is received in something else, i.e. essence. (3) Since *esse* in all other entities is therefore distinct from essence or quiddity, existence is communicated to such beings by something else; i.e., they are caused. Since that which exists through something else must be traced back to that which exists of itself, there must be something that causes the existence of everything else and that is identical with its act of existing. Otherwise one would regress to infinity in caused causes of existence, which Thomas here dismisses as unacceptable.

In qu. 2, a. 1 of *ST* I, Thomas rejects the claim that God's existence is self-evident to us in this life, and in a. 2 maintains that God's existence can be demonstrated by reasoning from knowledge of an existing effect to knowledge of God as the cause required for that effect to exist.

The *first way* or argument (art. 3) rests upon the fact that various things in our world of sense experience are moved. But whatever is moved is moved by something else. To justify this, Thomas reasons that to be moved is to be reduced from potentiality to actuality, and that nothing can reduce itself from potency to act; for it would then have to be in potency (if it is to be moved) and in act at the same time and in the same respect. (This does not mean that a mover must formally possess the act it is to communicate to something else if it is to move the latter; it must at least possess it virtually, i.e. have the power to communicate it.) Whatever is moved, therefore, must be moved by something else. One cannot regress to infinity with moved movers, for then there would be no first mover and, consequently, no other mover; for second movers do not move unless they are moved by a first mover. One must, therefore, infer the existence of a first mover which is moved by nothing else, and this "everyone understands to be God."

The *second way* takes as its point of departure an ordering of efficient causes as indicated to us by our investigation of sensible things. By this Thomas means that we perceive in the world of sensible things that certain efficient causes cannot exercise their causal activity unless they are also caused by something else. But nothing can be the efficient cause of itself, since it would then have to be prior to itself. One cannot regress to infinity in ordered efficient causes. In ordered efficient causes, the first is the cause of the intermediary, and the intermediary is the cause of the last whether the intermediary is one or many. Hence if there were no first efficient cause, there would be no intermediary and no last cause. Thomas concludes from this that one must acknowledge the existence of a first efficient cause, "which everyone names God."

The *third way* consists of two major parts. Some textual variants have complicated the proper interpretation of the first part. In brief, Aquinas appeals to the fact that certain things are subject to generation and corruption to show that they are "possible," i.e. capable of existing and not existing. Not all things can be of this kind (*revised text*), for that which has the possibility of not existing at some time does not exist. If, therefore, all things are capable of not existing, at some time there was nothing whatsoever. If that were so, even now there would be nothing, since what does not exist can only begin to exist through something else that exists. Therefore not all beings are capable of existing and not existing. There must be some necessary being. Since such a necessary, i.e. incorruptible, being might still be caused by something else, Thomas adds a second part to the argument. Every necessary being either depends on something else for its necessity or it does not. One cannot regress to infinity in necessary beings that depend on something else for their necessity. Therefore there must be some being that is necessary of itself and that does not depend on another cause for its necessity, i.e. God.

The statement in the first part to the effect that what has the possibility of not existing at some point does not exist has been subject to considerable dispute among commentators. Moreover, even if one grants this and supposes that every individual being is a "possible" and therefore has not existed at some point in the past, it does not easily follow from this that the totality of existing things will also have been nonexistent at some point in the past. Given this, some interpreters prefer to substitute for the third way the more satisfactory versions found in *SCG* I (ch. 15) and *SCG* II (ch. 15).

Thomas's *fourth way* is based on the varying degrees of perfection we discover among the beings we experience. Some are more or less good, more or less true, more or less noble, etc., than others. But the more and less are said of different things insofar as they approach in varying degrees something that is such to a maximum degree. Therefore there is something that is truest and best and noblest and hence that is also being to the maximum degree. To support this Thomas comments that those things that are true to the maximum degree also enjoy being to the maximum degree; in other words he appeals to the convertibility between being and truth (of being). In the second part of this argument Thomas argues that what is supremely such in a given genus is the cause of all other things in that genus. Therefore there is something that is the cause of being, goodness, etc., for all other beings, and this we call God.

Much discussion has centered on Thomas's claim that the more and less are said of different things insofar as they approach something that is such to the maximum degree. Some find this insufficient to justify the conclusion that a maximum must exist, and would here insert an appeal to efficient causality and his theory of participation. If certain entities share or participate in such a perfection only to a limited degree, they must receive that perfection from something else. While more satisfactory from a philosophical perspective, such an insertion seems to change the argument of the fourth way significantly.

The *fifth way* is based on the way things in the universe are governed. Thomas observes that certain things that lack the ability to know, i.e. natural bodies, act for an end. This follows from the fact that they always or at least usually act in the same way to attain that which is best. For Thomas this indicates that they reach their ends by "intention" and not merely from chance. And this in turn implies that they are directed to their ends by some knowing and intelligent being. Hence some intelligent being exists that orders natural things to their ends. This argument rests on final causality and should not be confused with any based on order and design.

Aquinas's frequently repeated denial that in this life we can know what God is should here be recalled. If we can know that God exists and what he is not, we cannot know what he is (see, e.g., *SCG* I, c. 30). Even when we apply the names of pure perfections to God, we first discover such perfections in limited fashion in creatures. What the names of such perfections are intended to signify may indeed be free from all imperfection, but every such name carries with it some deficiency in the way in which it signifies. When a name such as 'goodness', for instance, is signified abstractly (e.g., 'God is goodness'), this abstract way of signifying suggests that goodness does not subsist in itself. When such a name is signified concretely (e.g., 'God is good'), this concrete way of signifying implies some kind of composition between God and his goodness. Hence while such names are to be affirmed of God as regards that which they signify, the way in which they signify is to be denied of him.

This final point sets the stage for Thomas to apply his theory of analogy to the divine names. Names of pure perfections such as 'good', 'true', and 'being' cannot be applied to God with exactly the same meaning they have when affirmed of creatures (univocally), nor with entirely different meanings (equivocally). Hence they are affirmed of God and of creatures by an analogy based on the relationship that obtains between a creature viewed as an effect and God its uncaused cause. Because some minimum degree of similarity must obtain between any effect and its cause, Thomas is convinced that in some way a caused perfection imitates and participates in God, its uncaused and unparticipated source. Because no caused effect can ever be equal to its uncreated cause, every perfection that we affirm of God is realized in him in a way different from the way we discover it in creatures. This dissimilarity is so great that we can never have quidditative knowledge of God in this life (know what God is). But the similarity is sufficient for us to conclude that what we understand by a perfection such as goodness in creatures is present in God in unrestricted fashion. Even though Thomas's identification of the kind of analogy to be used in predicating divine names underwent some development, in mature works such as *On the Power of God* (qu. 7, a. 7), *SCG* I (c. 34), and *ST* I (qu. 13, a. 5), he identifies this as the analogy of "one to another," rather than as the analogy of "many to one." In none of these works does he propose using the analogy of "proportionality" that he had previously defended in *On Truth* (qu. 2, a. 11).

Theological virtues. While Aquinas is convinced that human reason can arrive at knowledge that God exists and at meaningful predication of the divine names, he does not think the majority of human beings will actually succeed in such an effort (*SCG* I, c. 4; *ST* II–IIae, qu. 2, a. 4). Hence he concludes that it was fitting for God to reveal such truths to mankind along with others that purely philosophical inquiry could never discover even in principle. Acceptance of the truth of divine revelation presupposes the gift of the theological virtue of faith in the believer. Faith is an infused virtue by reason of which we accept on God's authority what he has revealed to us. To believe is an act of the intellect that assents to divine truth as a result of a command on the part of the human will, a will that itself is moved by God through grace (*ST* II–IIae, qu. 2, a. 9).

For Thomas the theological virtues, having God (the ultimate end) as their object, are prior to all other virtues whether natural or infused. Because the ultimate end must be present in the intellect before it is present to the will, and because the ultimate end is present in the will by reason of hope and charity (the other two theological virtues), in this respect faith is prior to hope and charity. Hope is the theological virtue through which we trust that with divine assistance we will attain the infinite good – eternal enjoyment of God (*ST* II–IIae, qu. 17, aa. 1–2). In the order of generation, hope is prior to charity; but in the order of perfection, charity is prior both to hope and to faith. While neither faith nor hope will remain in those who reach the eternal vision of God in the life to come, charity will endure in the blessed. It is a virtue or habitual form that is infused into the soul by God and that inclines us to love him for his own sake. If charity is more excellent than faith or hope (*ST* II–IIae, qu. 23, a. 6), through charity the acts of all other virtues are ordered to God, their ultimate end (qu. 23, a. 8).

See also ARISTOTLE, PHILOSOPHY OF RELIGION, THOMISM. J.F.W.

Arabic philosophy, the philosophy produced in Arabic by philosophers of various ethnic and religious backgrounds who lived in societies in which Islamic civilization was dominant and who identified with its cultural values. (The appellation 'Islamic philosophy' is misleading, for it suggests a specific religious content that was not necessarily there – just as medieval Latin philosophy is not "Christian" philosophy.) In the historical evolution of Western philosophy it is the heir to post-Plotinian late Greek philosophy and the immediate precursor of later medieval philosophy, which it heavily influenced and to which it exhibits a parallel but independent development after Avicenna well into the twentieth century.

The philosophical curriculum of higher education that had spread among the Hellenized peoples of Egypt, the Middle East, and Iran in the sixth century followed the classification of the sciences current in Alexandria, a classification that had developed from that of Aristotle's works. Aristotle's *Organon*, including the *Rhetoric* and *Poetics*, and prefaced by Porphyry's *Isagoge*, constituted the canonical nine books on logic, the instrument of philosophy. Philosophy proper was then divided into theoretical and practical: theoretical philosophy was further subdivided into physics, mathematics, and metaphysics; and practical into ethics, economics (household management), and politics. Carriers of this higher education were primarily the Eastern churches and monastic centers in the Fertile Crescent. With the advent of Islam in the seventh century and the eventual spread of Arabic as the language of learning, the entire curriculum was translated upon demand into Arabic by Syriac-speaking Christians in the eighth through the tenth centuries. The demand came from Arab intellectuals, who by the time of the translations had developed a significant scholarly tradition of their own and actively commissioned the translations. The entire corpus of Aristotle's writings, together with the complete range of commentaries from Alexander of Aphrodisias onward, constituted in Arabic the standard textbooks in logic, physics (including meteorology, the theory of the soul, and zoology), metaphysics, and ethics. Metaphysics was also studied as a rule in conjunction with or in the light of the pseudo-Aristotelian *Theologia Aristotelis* (selections from Plotinus's *Enneads*, Books 4–6) and the *Liber de causis*, along with other selections from Proclus's *Elements of Theology*. Mathematics included geometry (Euclid's *Elements*), astronomy (Ptolemy's *Almagest*), arithmetic (Nicomachus's *Introduction*), and music (Ptolemy's *Harmonics*). Economics was based almost exclusively on the neo-Pythagorean Bryson's *Oikonomikos*, while politics drew mainly on Plato's *Republic* and the *Laws* and especially on the pseudepigraphic correspondence between Aristotle and Alexander (Aristotle's *Politics* was known in Arabic in fragmentary form). In medicine, which was considered an applied science and as such remained outside this classification, Galen's entire works were translated. His abridgments of Plato and his Stoicizing logic formed the basic source of knowledge on these subjects in Arabic.

The early history of Arabic philosophy presents two independent lines of development. One is associated with the first philosopher and Arab polymath, al-Kindī (d.873) and his followers, notably as-Sarakhsī (d.889), Abū-Zayd al-Balkhī (d.934), and al-ʹĀmirī (d.992). These philosophers, who appear to stand closer to the Neoplatonism of Athens than to the neo-Aristotelianism of Alexandria, sought in their works to present the various parts of philosophy to an Arab audience, integrate them into Islamic intellectual life, and solve the philosophical problems that arose in the process. The famous physician Rhazes (Abū-Bakr ar-Rāzī, d.925) may be tenuously related to this line, although he appears to be mostly an autodidact and his philosophy was decidedly more eclectic, leaving no following. The second is that of the Aristotelians of Baghdad, founded by the Nestorian scholar and translator Mattā Ibn Yānus (d.940). His Aristotelianism can be traced directly to the Alexandrian commentators and reaches beyond them to Alexander of Aphrodisias and Themistius. His students, al-Fārābī (d.950) and Yahyā Ibn ʻAdī (d.974), and the wide circle of disciples of the latter, prominent among whom are Abū-Sulaymān as-Sijistānī (d.c.985), ʻĪsā Ibn-Zurʹa (d.1008), al-Hasan Ibn-Suwār (d.c.1030), and Abū-l-Faraj Ibn at-Tayyib (d.1043), engaged in rigorous textual analysis and philosophical interpretation of Aristotle's works and composed independent monographs on all branches of philosophy. The Aristotelian line of Baghdad, and especially the work of al-Fārābī, was transmitted to Islamic Spain (al-Andalus) toward the end of the tenth century and formed the basis of the philosophical tradition there, whose major exponents were Ibn Bājja (Avempace, d.1139), Ibn Tufayl (d.1186), Averroes (Ibn Rushd, d.1198), and Maimonides (Ibn Maymun, d.1204). This tradition came to an end with the *reconquista* of all Islamic Spain except Granada about two decades after the death of Ibn Tumlūs (d.1223), the last major Andalusian philosopher.

These two lines eventually merge in the work of Avicenna, who set himself the task of synthesizing, in the light of concerns valid in his time, the divergent tendencies of Aristotelian philosophy as it had developed throughout the ages. The Alexandrian schema of the classification of the sciences, which was adopted by Arabic philosophy, implicitly also presented, by means of the connections it established among the various subjects, a blueprint of a work that would encompass all philosophy. Philosophers prior to Avicenna, both the Greeks after Plotinus and the Arabs, failed to note its potential as an outline for a comprehensive work on all philosophy, and had worked on different parts of it. Avicenna was the first to perceive this and to create in his various writings an internally consistent system having mutually interdependent parts and based on the syllogistic logic of Aristotle. His philosophical summae thus mark the end of ancient and the beginning of Scholastic philosophy. In these works Avicenna paid relatively little attention to certain parts of philosophy, in particular the mathematical part of theoretical, and virtually the entirety of practical, philosophy. As a result, Arabic philosophy after him concentrated on three major fields – logic, physics, and metaphysics – which became the norm. Practical philosophy developed along different lines, to a large extent divorced from mainstream philosophy. The highly influential work by Miskawayh (d.1030) on ethics provided a model that was followed by later treatises, which constituted a separate genre of philosophical writings. As for mathematics, its different parts were pursued largely independently of the rest of philosophy.

After Avicenna, Arabic philosophy was dominated by his thought and developed along the lines of the reconstructed Peripateticism he established. In the first place, his powerful integrative systematization of philosophy elicited a reaction by certain philosophers toward a more pristine Aristotelianism, notably by Averroes, ‘Abd-al-Latīf al-Baghdādī (d.1231), and the eighteenth-century Ottoman scholar Yanyali Esat (As’ad of Yanyā, d.1730), who even executed new Arabic translations from the Greek of some of Aristotle’s physical works. Secondly, it generated among his followers, notable among whom are Nasīr-ad-Dīn at-Tūsī (d.1274) and Qutb-ad-Dīn ar-Rāzī (d.1364), a long series of philosophically fecund commentaries and super-commentaries. Thirdly, it forced most theological writing to adopt logic as its method, and philosophical, rather than theological, analysis as the means of argumentation, a procedure established by al-Ghazālī (d.1111) and consolidated by Fakhr-ad-Dīn ar-Rāzī (d.1209). And fourthly, it formed the basis for the further development of his metaphysics (in particular the concepts of essence and existence and the schema of emanation) through the incorporation of the illuminationist philosophy of Suhrawardī of Aleppo (d.1193) and the mystical theories of Ibn ‘Arabī (d.1240) in the works of Shiite philosophers active since Safavid times (sixteenth century). This movement, initiated by Mīr Dāmād (d.1632) and developed by his pupil Mullā Fadrā (d.1640), has continued after the latter’s death among Iranian philosophers writing partly also in Persian.

The colonization of the Arab world by Western powers since the nineteenth century has resulted in the spread of modern European, and especially French, philosophy among Arab intellectuals. Modern Arab philosophical thought is now developing along these lines while at the same time efforts are being made to relate it to traditional Arabic philosophy.

ārādhya (Sanskrit, ‘object of worship’, ‘reverence’). In traditional Indian society, reverence was almost a way of life. Elders, especially one’s parents and teachers, were held in godlike esteem. The Indians revered life in any form as sacred; hence, *ahimsā* (nonviolence) and vegetarianism were two important features of the ideal Indian life. In the Hindu polytheistic tradition, which continues even today, the countless Vedic deities, along with the later gods and goddesses in the Hindu pantheon, serve as *ārādhya* objects. A popular form of *ārādhya* in today’s Hindu society is often a chosen deity worshipped in a household. **See also** AHIMSĀ. D.K.C.

Arcesilaus of Pitane (c.315–242 B.C.), Greek Skeptic philosopher, founder of the Middle Academy. Influenced by Socratic elenchus, he claimed that, unlike Socrates, he was not even certain that he was certain of nothing. He shows the influence of Pyrrho in attacking the Stoic doctrine that the subjective certainty of the wise is the criterion of truth. At the theoretical level he advocated *epochē*, suspension of rational judgment; at the practical, he argued that *eulogon*, probability, can justify action – an early version of coherentism. His ethical views were not extreme; he held, e.g., that one should attend to one’s own life rather than external objects. Though he wrote nothing except verse, he led the Academy into two hundred years of Skepticism. R.C.

Archytas (fl. 400–350 B.C.), Greek Pythagorean philosopher from Tarentum in southern Italy. He was elected general seven times and sent a ship to rescue Plato from Dionysius II of Syracuse in 361.

He is famous for solutions to specific mathematical problems, such as the doubling of the cube, but little is known about his general philosophical principles. His proof that the numbers in a superparticular ratio have no mean proportional has relevance to music theory, as does his work with the arithmetic, geometric, and harmonic means. He gave mathematical accounts of the diatonic, enharmonic, and chromatic scales and developed a theory of acoustics. Fragments 1 and 2 and perhaps 3 are authentic, but most material preserved in his name is spurious. **See also** PYTHAGORAS. C.A.H.

Arendt, Hannah (1906–75), German-born American social and political theorist. She was educated in her native Germany, studying with Heidegger and Jaspers; fled to France in 1933; and emigrated in 1941 to the United States, where she taught at various universities. Her major works are *The Origins of Totalitarianism* (1951), *The Human Condition* (1958), *Between Past and Future* (1961), *On Revolution* (1963), *Crises of the Republic* (1972), and *The Life of the Mind* (1978).

In Arendt's view, for reasons established by Kant and deepened by Nietzsche, there is a breach between being and thinking, one that cannot be closed by thought. Understood as philosophizing or contemplation, thinking is a form of egoism that isolates us from one another and our world. Despite Kant, modernity remains mired in egoism, a condition compounded by the emergence of a "mass" that consists of bodies with needs temporarily met by producing and consuming and which demands governments that minister to these needs. In place of thinking, laboring, and the administration of things now called democracy, all of which are instrumental but futile as responses to the "thrown" quality of our condition, Arendt proposed to those capable of it a mode of being, *political action*, that she found in pronounced form in pre-Socratic Greece and briefly but gloriously at the founding of the Roman and American republics. Political action is initiation, the making of beginnings that can be explained neither causally nor teleologically. It is done in the space of appearances constituted by the presence of other political actors whose responses – the telling of equally unpredictable stories concerning one another's actions – determine what actions are taken and give character to the acting participants. In addition to the refined discernments already implied, political action requires the courage to initiate one knows not what. Its outcome is power; not over other people or things but mutual empowerment to continue acting in concert and thereby to overcome egoism and achieve (positive) freedom and humanity.

aretaic. See ARETE.

***arete*,** ancient Greek term meaning 'virtue' or 'excellence'. In philosophical contexts, the term was used mainly of virtues of human character; in broader contexts, *arete* was applicable to many different sorts of excellence. The cardinal virtues in the classical period were courage, wisdom, temperance (*sophrosune*), piety, and justice.

Sophists such as Protagoras claimed to teach such virtues, and Socrates challenged their credentials for doing so. Several early Platonic dialogues show Socrates asking after definitions of virtues, and Socrates investigates *arete* in other dialogues as well. Conventional views allowed that a person can have one virtue (such as courage) but lack another (such as wisdom), but Plato's *Protagoras* shows Socrates defending his thesis of the unity of *arete*, which implies that a person who has one *arete* has them all. Platonic accounts of the cardinal virtues (with the exception of piety) are given in Book IV of the *Republic*. Substantial parts of the *Nicomachean Ethics* of Aristotle are given over to discussions of *arete*, which he divides into virtues of character and virtues of intellect. This discussion is the ancestor of most modern theories of virtue ethics.

argument, a sequence of statements some of which (the *premises*) purport to give reason to accept another of them, the *conclusion*. Since we speak of bad arguments and weak arguments, the premises of an argument need not really support the conclusion, but they must give some appearance of doing so or 'argument' is misapplied. Logic is mainly concerned with the question of validity: whether *if* the premises are true we would have reason to accept the conclusion. A valid argument with true premises is called *sound.* A valid deductive argument is one such that if we accept the premises we are *logically* bound to accept the conclusion and if we reject the conclusion we are logically bound to reject one or more of the premises. Alternatively, the premises logically entail the conclusion.

A good inductive argument – some would reserve 'valid' for deductive arguments – is one such that if we accept the premises we are logically bound to regard the conclusion as probable and, in addition, as more probable than it would be if the premises should be false. A few arguments have only one premise and/or more than one conclusion.

Arianism, diverse but related teachings in early Christianity that subordinated the Son to God the Father. In reaction the church developed its doctrine of the Trinity, whereby the Son (and Holy Spirit), though distinct persons (*hypostases*), share with the Father, as his ontological equals, the one being or substance (*ousia*) of God. Arius (c.250–c.336) taught in Alexandria, where, on the hierarchical model of Middle Platonism, he sharply distinguished Scripture's transcendent God from the *Logos* or Son incarnate in Jesus. The latter, subject to suffering and humanly obedient to God, is inferior to the immutable Creator, the object of that obedience. God alone is eternal and ungenerated; the Son, divine not by nature but by God's choosing, is generated, with a beginning: the unique creature, through whom all else is made. The Council of Nicaea, in 325, condemned Arius and favored his enemy Athanasius, affirming the Son's creatorhood and full deity, having the same being or substance (*homoousios*) as the Father. Arianism still flourished, evolving into the extreme view that the Son's being was neither the same as the Father's nor like it (*homoiousios*), but unlike it (*anomoios*). This too was anathematized, by the Council of 381 at Constantinople, which, ratifying what is commonly called the Nicene Creed, sealed orthodox Trinitarianism and the equality of the three persons against Arian subordinationism. **See also** **HOMOOUSIOS.** A.E.L.

Aristippus of Cyrene. See CYRENAICS.

Aristotle (384–322 B.C.), preeminent Greek philosopher born in Stagira, hence sometimes called the Stagirite. Aristotle came to Athens as a teenager and remained for two decades in Plato's Academy. Following Plato's death in 347, Aristotle traveled to Assos and to Lesbos, where he associated with Theophrastus and collected a wealth of biological data, and later to Macedonia, where he tutored Alexander the Great. In 335 he returned to Athens and founded his own philosophical school in the Lyceum. The site's colonnaded walk (*peripatos*) conferred on Aristotle and his group the name 'the Peripatetics'. Alexander's death in 323 unleashed anti-Macedonian forces in Athens. Charged with impiety, and mindful of the fate of Socrates, Aristotle withdrew to Chalcis, where he died.

Chiefly influenced by his association with Plato, Aristotle also makes wide use of the pre-Socratics. A number of works begin by criticizing and, ultimately, building on their views. The direction of Plato's influence is debated. Some scholars see Aristotle's career as a measured retreat from his teacher's doctrines. For others he began as a confirmed anti-Platonist but returned to the fold as he matured. More likely, Aristotle early on developed a keenly independent voice that expressed enduring puzzlement over such Platonic doctrines as the separate existence of Ideas and the construction of physical reality from two-dimensional triangles. Such unease was no doubt heightened by Aristotle's appreciation for the evidential value of observation as well as by his conviction that long-received and well-entrenched opinion is likely to contain at least part of the truth.

Aristotle reportedly wrote a few popular works for publication, some of which are dialogues. Of these we have only fragments and reports. Notably lost are also his lectures on the good and on the Ideas. Ancient cataloguers also list under Aristotle's name some 158 constitutions of Greek states. Of these, only the Constitution of Athens has survived, on a papyrus discovered in 1890. What remains is an enormous body of writing on virtually every topic of philosophical significance. Much of it consists of detailed lecture notes, working drafts, and accounts of his lectures written by others. Although efforts may have been under way in Aristotle's lifetime, Andronicus of Rhodes, in the first century B.C., is credited with having given the Aristotelian corpus its present organization. Virtually no extant manuscripts predate the ninth century A.D., so the corpus has been transmitted by a complex history of manuscript transcription. In 1831 the Berlin Academy published the first critical edition of Aristotle's work. Scholars still cite Aristotle by page, column, and line of this edition.

Logic and language. The writings on logic and language are concentrated in six early works: *Categories, On Interpretation, Prior Analytics, Posterior Analytics, Topics*, and *Sophistical Refutations*. Known since late antiquity as the *Organon*, these works share a concern with what is now called semantics. The *Categories* focuses on the relation between uncombined terms, such as 'white' or 'man', and the items they signify; *On Interpretation* offers an account of how terms combine to yield simple statements; *Prior Analytics* provides a systematic account of how three terms must be distributed in two categorical statements so as to yield logically a third such statement; *Posterior Analytics* specifies the conditions that categorical statements must meet to play a role in scientific explanation. The *Topics*, sometimes said to include *Sophistical Refutations*, is a handbook of "topics" and techniques for dialectical arguments concerning, principally, the four predicables: accident (what may or may not belong to a subject, as sitting belongs to Socrates); definition (what signifies a subject's essence, as rational animal is the essence of man); proprium (what is not in the essence of a subject but is unique to or counterpredicable of it, as all and only persons are risible); and genus (what is in the essence of subjects differing in species, as animal is in the essence of both men and oxen).

Categories treats the basic kinds of things that exist and their interrelations. Every uncombined term, says Aristotle, signifies essentially something in one of ten categories – a substance, a quantity, a quality, a relative, a place, a time, a position, a having, a doing, or a being affected. This doctrine underlies Aristotle's admonition that there are as many proper or per se senses of 'being' as there are categories. In order to isolate the things that exist primarily, namely, primary substances, from all other things and to give an account of their nature, two asymmetric relations of ontological dependence are employed. First, substance (*ousia*) is distinguished from the accidental categories by the fact that every accident is *present in* a substance and, therefore, cannot exist without a substance in which to inhere. Second, the category of substance itself is divided into ordinary individuals or primary substances, such as Socrates, and secondary substances, such as the species man and the genus animal. Secondary substances are *said of* primary substances and indicate what kind of thing the subject is. A mark of this is that both the name and the definition of the secondary substance can be predicated of the primary substance, as both *man* and *rational animal* can be predicated of Socrates. Universals in non-substance categories are also said of subjects, as color is said of white. Therefore, directly or indirectly, everything else is either present in or said of primary substances and without them nothing would exist. And because they are neither present in a subject nor said of a subject, primary substances depend on nothing else for their existence. So, in the *Categories*, the ordinary individual is ontologically basic.

On Interpretation offers an account of those meaningful expressions that are true or false, namely, statements or assertions. Following Plato's *Sophist*, a simple statement is composed of the semantically heterogeneous parts, name (*onoma*) and verb (*rhema*). In 'Socrates runs' the name has the strictly referential function of signifying the subject of attribution. The verb, on the other hand, is essentially predicative, signifying something holding of the subject. Verbs also indicate when something is asserted to hold and so make precise the statement's truth conditions. Simple statements also include general categorical statements. Since medieval times it has become customary to refer to the basic categoricals by letters: (*A*) Every man is white, (*E*) No man is white, (*I*) Some man is white, and (*O*) Not every man is white. *On Interpretation* outlines their logical relations in what is now called the square of opposition: *A & E* are contraries, *A & O* and *E & I* are contradictories, and *A & I* and *E & O* are superimplications. That *A* implies *I* reflects the no longer current view that all affirmative statements carry existential import.

One ambition of *On Interpretation* is a theory of the truth conditions for all statements that affirm or deny one thing or another. However, statements involving future contingencies pose a special problem. Consider Aristotle's notorious sea battle. Either it will or it will not happen tomorrow. If the first, then the statement 'There will be a sea battle tomorrow' is *now* true. Hence, it is now fixed that the sea battle occur tomorrow. If the second, then it is now fixed that the sea battle not occur tomorrow. Either way there can be no future contingencies. Although some hold that Aristotle would embrace the determinism they find implicit in this consequence, most argue either that he suspends the law of excluded middle for future contingencies or that he denies the principle of bivalence for future contingent statements. On the first option Aristotle gives up the claim that either the sea battle will happen tomorrow or not. On the second he keeps the claim but allows that future contingent statements are neither true nor false. Aristotle's evident attachment to the law of excluded middle, perhaps, favors the second option.

Prior Analytics marks the invention of logic as a formal discipline in that the work contains the first virtually complete system of logical inference, sometimes called *syllogistic*. The fact that the first chapter of the *Prior Analytics* reports that there is a syllogism whenever, certain things being stated, something else follows of necessity might suggest that Aristotle intended to capture a general notion of logical consequence. However, the syllogisms that constitute the system of the *Prior Analytics* are restricted to the basic categorical statements introduced in *On Interpretation*. A syllogism consists of three different categorical statements: two premises and a conclusion. The *Prior Analytics* tells us which pairs of categoricals logically yield a third. The fourteen basic valid forms are divided into three figures and, within each figure, into moods. The system is foundational because second- and third-figure syllogisms are reducible to first-figure syllogisms, whose validity is self-evident. Although syllogisms are conveniently written as conditional sentences, the syllogistic proper is, perhaps, best seen as a system of valid deductive inferences rather than as a system of valid conditional sentences or sentence forms.

Posterior Analytics extends syllogistic to science and scientific explanation. A science is a deductively ordered body of knowledge about a definite genus or domain of nature. Scientific knowledge (*episteme*) consists not in knowing *that*, e.g., there is thunder in the clouds, but rather in knowing *why* there is thunder. So the theory of scientific knowledge is a theory of explanation and the vehicle of explanation is the first-figure syllogism *Barbara:* If (1) *P* belongs to all *M* and (2) *M* belongs to all *S*, then (3) *P* belongs to all *S*. To explain, e.g., why there is thunder, i.e. why there is noise in the clouds, we say: (3′) Noise (*P*) belongs to the clouds (*S*) because (2′) Quenching of fire (*M*) belongs to the clouds (*S*) and (1′) Noise (*P*) belongs to quenching of fire (*M*). Because what is explained in science is invariant and holds of necessity, the premises of a scientific or *demonstrative syllogism* must be necessary. In requiring that the premises be prior to and more knowable than the conclusion, Aristotle embraces the view that explanation is asymmetrical: knowledge of the conclusion depends on knowledge of each premise, but each premise can be known independently of the conclusion. The premises must also give the causes of the conclusion. To inquire why *P* belongs to *S* is, in effect, to seek the middle term that gives the cause. Finally, the premises must be immediate and non-demonstrable. A premise is immediate just in case there is no middle term connecting its subject and predicate terms. Were *P* to belong to *M* because of a new middle, *M1*, then there would be a new, more basic premise that is essential to the full explanation.

Ultimately, explanation of a received fact will consist in a chain of syllogisms terminating in primary premises that are immediate. These serve as axioms that define the science in question because they reflect the essential nature of the fact to be explained – as in (1′) The essence of thunder lies in the quenching of fire. Because they are immediate, primary premises are not capable of syllogistic demonstration, yet they must be known if syllogisms containing them are to constitute knowledge of the conclusion. Moreover, were it necessary to know the primary premises syllogistically, demonstration would proceed infinitely or in a circle. The first alternative defeats the very possibility of explanation and the second undermines its asymmetric character. Thus, the primary premises must be known by the direct grasp of the mind (*noûs*). This just signals the appropriate way for the highest principles of a science to be known – even demonstrable propositions can be known directly, but they are explained only when located within the structure of the relevant science, i.e. only when demonstrated syllogistically. Although all sciences exhibit the same formal structure and use certain common principles, different sciences have different primary premises and, hence, different subject matters. This "one genus to one science" rule legislates that each science and its explanations be autonomous.

Aristotle recognizes three kinds of intellectual discipline. *Productive* disciplines, such as house building, concern the making of something external to the agent. *Practical* disciplines, such as ethics, concern the doing of something not separate from the agent, namely, action and choice. *Theoretical* disciplines are concerned with truth for its own sake. As such, they alone are sciences in the special sense of the *Posterior Analytics*. The three main kinds of special science are individuated by their objects – natural science by objects that are separate but not changeless, mathematics by objects that are changeless but not separate, and theology by separate and changeless objects. The mathematician studies the same objects as the natural scientist but in a quite different way. He takes an actual object, e.g. a chalk figure used in demonstration, and abstracts from or "thinks away" those of its properties, such as definiteness of size and imperfection of shape, that are irrelevant to its standing as a perfect exemplar of the purely mathematical properties under investigation. Mathematicians simply treat this abstracted circle, which is not separate from matter, as if it were separate. In this way the theorems they prove about the object can be taken as universal and necessary.

Physics. As the science of nature (*physis*), physics studies those things whose principles and causes of change and rest are internal. Aristotle's central treatise on nature, the *Physics*, analyzes the most general features of natural phenomena: cause, change, time, place, infinity, and continuity. The doctrine of the *four causes* is especially important in Aristotle's work. A cause (*aitia*) is something like an explanatory factor. The *material cause* of a house, for instance, is the matter (*hyle*) from which it is built; the moving or *efficient cause* is the builder, more exactly, the form in the builder's soul; the *formal cause* is its plan or form (*eidos*); and the *final cause* is its purpose or end (*telos*): provision of shelter. The complete explanation of the coming to be of a house will factor in all of these causes. In natural phenomena, efficient, formal, and final causes often coincide. The form transmitted by the father is both the efficient cause and the form of the child, and the latter is glossed in terms of the child's end or complete development. This explains why Aristotle often simply contrasts matter and form. Although its objects are compounds of both, physics gives priority to the study of natural form. This accords with the *Posterior Analytics′* insistence that explanation proceed through causes that give the essence and reflects Aristotle's commitment to teleology. A natural process counts essentially as the development of, say, an oak or a man because its very identity depends on the complete form realized at its end. As with all things natural, the end is an internal governing principle of the process rather than an external goal.

All natural things are subject to change (*kinesis*). Defined as the actualization of the potential *qua* potential, a change is not an ontologically basic item. There is no category for changes. Rather, they are reductively explained in terms of more basic things – substances, properties, and potentialities. A pale man, e.g., has the potentiality to be or become tanned. If this potentiality is utterly unactualized, no change will ensue; if completely actualized, the change will have ended. So the potentiality must be actualized but not, so to speak, exhausted; i.e., it must be actualized *qua potentiality*. Designed for the ongoing operations of the natural world, the *Physics′* definition of change does not cover the generation and corruption of substantial items themselves. This sort of change, which involves matter and elemental change, receives extensive treatment in *On Generation and Corruption*.

Aristotle rejects the atomists' contention that the world consists of an infinite totality of indivisible atoms in various arrangements. Rather, his basic stuff is uniform elemental matter, any part of which is divisible into smaller such parts. Because nothing that is actually infinite can exist, it is only in principle that matter is always further dividable. So while countenancing the potential infinite, Aristotle squarely denies the *actual infinite*. This holds for the motions of the sublunary elemental bodies (earth, air, fire, and water) as well as for the circular motions of the heavenly bodies (composed of a fifth element, aether, whose natural motion is circular). These are discussed in *On the Heavens*. The four sublunary elements are further discussed in *Meteorology*, the fourth book of which might be described as an early treatise on chemical combination.

Psychology. Because the soul (*psyche*) is officially defined as the form of a body with the potentiality for life, psychology is a subfield of natural science. In effect, Aristotle applies the apparatus of form and matter to the traditional Greek view of the soul as the principle and cause of life. Although even the nutritive and reproductive powers of plants are effects of the soul, most of his attention is focused on topics that are psychological in the modern sense. *On the Soul* gives a general account of the nature and number of the soul's principal cognitive faculties. Subsequent works, chiefly those collected as the *Parva naturalia*, apply the general theory to a broad range of psychological phenomena from memory and recollection to dreaming, sleeping, and waking.

The soul is a complex of faculties. Faculties, at least those distinctive of persons, are capacities for cognitively grasping objects. Sight grasps colors, smell odors, hearing sounds, and the mind grasps universals. An organism's form is the particular organization of its material parts that enable it to exercise these characteristic functions. Because an infant, e.g., has the capacity to do geometry, Aristotle distinguishes two varieties of capacity or potentiality (*dynamis*) and actuality (*entelecheia*). The infant is a geometer *only* in potentiality. *This first potentiality* comes to him simply by belonging to the appropriate species – i.e., by coming into the world endowed with the potential to develop into a competent geometer. By actualizing, through experience and training, this first potentiality, he acquires a *first actualization*. This actualization is also a *second potentiality*, since it renders him a competent geometer able to exercise his knowledge at will. The exercise itself is a *second actualization* and amounts to active contemplation of a particular item of knowledge – e.g., the Pythagorean theorem. So the soul is further defined as the first actualization of a complex natural body.

Faculties, like sciences, are individuated by their objects. Objects of perception (*aisthesis*) fall into three general kinds. *Special* (proper) *sensibles*, such as colors and sounds, are directly perceived by one and only one sense and are immune to error. They demarcate the five special senses: sight, hearing, smell, taste, and touch. *Common sensibles*, such as movement and shape, are directly perceived by more than one special sense. Both special and common sensibles are proper objects of perception because they have a direct causal effect on the perceptual system. By contrast, the son of Diares is an *incidental sensible* because he is perceived not directly but as a consequence of directly perceiving something else that happens to be the son of Diares – e.g., a white thing.

Aristotle calls the mind (*noûs*) the place of forms because it is able to grasp objects apart from matter. These objects are nothing like Plato's separately existing Forms. As Aristotelian universals, their existence is entailed by and depends on their having instances. Thus, *On the Soul*'s remark that universals are "somehow in the soul" only reflects their role in ensuring the autonomy of thought. The mind has no organ because it is not the form or first actualization of any physical structure. So, unlike perceptual faculties, it is not strongly dependent on the body. However, the mind thinks its objects by way of images, which are something like internal representations, and these are physically based. Insofar as it thus depends on imagination (*phantasia*), the mind is weakly dependent on the body. This would be sufficient to establish the naturalized nature of Aristotle's mind were it not for what some consider an incurably dualist intrusion. In distinguishing something in the mind that makes all things from something that becomes all things, Aristotle introduces the notorious distinction between the active and passive intellects and may even suggest that the first is separable from the body. Opinion on the nature of the active intellect diverges widely, some even discounting it as an irrelevant insertion. But unlike perception, which depends on external objects, thinking is up to us. Therefore, it cannot simply be a matter of the mind's being affected. So Aristotle needs a mechanism that enables us to produce thoughts autonomously. In light of this functional role, the question of active intellect's ontological status is less pressing.

Biology. Aristotle's biological writings, which constitute about a quarter of the corpus, bring biological phenomena under the general framework of natural science: the four causes, form and matter, actuality and potentiality, and especially the teleological character of natural processes. If the *Physics* proceeds in an a priori style, the *History of Animals, Parts of Animals*, and *Generation of Animals* achieve an extraordinary synthesis of observation, theory, and general scientific principle. *History of Animals* is a comparative study of generic features of animals, including analogous parts, activities, and dispositions. Although its morphological and physiological descriptions show surprisingly little interest in teleology, *Parts of Animals* is squarely teleological. Animal parts, especially organs, are ultimately differentiated by function rather than morphology.

The composition of, e.g., teeth and flesh is determined by their role in the overall functioning of the organism and, hence, requires teleology. *Generation of Animals* applies the form-matter and actuality-potentiality distinctions to animal reproduction, inheritance, and the development of accidental characteristics. The species form governs the development of an organism and determines what the organism is essentially. Although in the *Metaphysics* and elsewhere accidental characteristics, including inherited ones, are excluded from science, in the biological writings form has an expanded role and explains the inheritance of non-essential characteristics, such as eye color. The more fully the father's form is imposed on the minimally formed matter of the mother, the more completely the father's traits are passed on to the offspring. The extent to which matter resists imposition of form determines the extent to which traits of the mother emerge, or even those of more distant ancestors.

Aristotle shared the Platonists' interest in animal classification. Recent scholarship suggests that this is less an interest in elaborating a Linnean-style taxonomy of the animal kingdom than an interest in establishing the complex differentiae and genera central to definitions of living things. The biological works argue, moreover, that no single differentia could give the whole essence of a species and that the differentiae that do give the essence will fall into more than one division. If the second point rejects the method of dichotomous division favored by Plato and the Academy, the first counters Aristotle's own standard view that essence can be reduced to a single final differentia. The biological sciences are not, then, automatically accommodated by the *Posterior Analytics* model of explanation, where the essence or explanatory middle is conceived as a single causal property.

A number of themes discussed in this section are brought together in a relatively late work, *Motion of Animals*. Its psychophysical account of the mechanisms of animal movement stands at the juncture of physics, psychology, and biology.

Metaphysics. In Andronicus's edition, the fourteen books now known as the *Metaphysics* were placed after the *Physics*, whence comes the word 'metaphysics', whose literal meaning is 'what comes after the physics'. Aristotle himself prefers 'first philosophy' or 'wisdom' (*sophia*). The subject is defined as the theoretical science of the causes and principles of what is most knowable. This makes metaphysics a limiting case of Aristotle's broadly used distinction between what is better known to us and what is better known by nature. The genus animal, e.g., is better known by nature than the species man because it is further removed from the senses and because it can be known independently of the species. The first condition suggests that the most knowable objects would be the separately existing and thoroughly non-sensible objects of theology and, hence, that metaphysics is a special science. The second condition suggests that the most knowable objects are simply the most general notions that apply to things in general. This favors identifying metaphysics as the general science of being *qua* being. Special sciences study restricted modes of being. Physics, for instance, studies being *qua* having an internal principle of change and rest. A general science of being studies the principles and causes of things that are, simply insofar as they *are*. A good deal of the *Metaphysics* supports this conception of metaphysics. For example, Book IV, on the principle of non-contradiction, and Book X, on unity, similarity, and difference, treat notions that apply to anything whatever. So, too, for the discussion of form and actuality in the central books, VII, VIII, and IX. Book XII, on the other hand, appears to regard metaphysics as the special science of theology.

Aristotle himself attempts to reconcile these two conceptions of metaphysics. Because it studies immovable substance, theology counts as first philosophy. However, it is also general precisely because it is first, and so it will include the study of being *qua* being. Scholars have found this solution as perplexing as the problem. Although Book XII proves the causal necessity for motion of an eternal substance that is an unmoved mover, this establishes no conceptual connection between the forms of sensible compounds and the pure form that is the unmoved mover. Yet such a connection is required, if a single science is to encompass both.

Problems of reconciliation aside, Aristotle had to face a prior difficulty concerning the very possibility of a general science of being. For the *Posterior Analytics* requires the existence of a genus for each science but the *Metaphysics* twice argues that being is not a genus. The latter claim, which Aristotle never relinquishes, is implicit in the *Categories*, where being falls directly into kinds, namely, the categories. Because these highest genera do not result from differentiation of a single genus, no univocal sense of being covers them. Although being is, therefore, ambiguous in as many ways as there are categories, a thread connects them. The ontological priority accorded primary substance in the *Categories* is made part of the very definition of non-substantial entities in the *Metaphysics:* to be an accident is by definition to be an accident of some substance. Thus, the different senses of being all refer to the primary kind of being, substance, in the way that exercise, diet, medicine, and climate are healthy by standing in some relation to the single thing health. The discovery of *focal meaning*, as this is sometimes called, introduces a new way of providing a subject matter with the internal unity required for science. Accordingly, the *Metaphysics* modifies the strict "one genus to one science" rule of the *Posterior Analytics*. A single science may also include objects whose definitions are different so long as these definitions are related focally to one thing. So focal meaning makes possible the science of being *qua* being.

Focal meaning also makes substance the central object of investigation. The principles and causes of being in general can be illuminated by studying the principles and causes of the primary instance of being. Although the *Categories* distinguishes primary substances from other things that are and indicates their salient characteristics (e.g., their ability to remain one and the same while taking contrary properties), it does not explain why it is that primary substances have such characteristics. The difficult central books of the *Metaphysics* – VII, VIII, and IX – investigate precisely this. In effect, they ask what, primarily, about the *Categories'* primary substances explains their nature. Their target, in short, is the *substance* of the primary substances of the *Categories*. As concrete empirical particulars, the latter are compounds of form and matter (the distinction is not explicit in the *Categories*) and so their substance must be sought among these internal structural features. Thus, *Metaphysics* VII considers form, matter, and the compound of form and matter, and quickly turns to form as the best candidate. In developing a conception of form that can play the required explanatory role, the notion of essence (*to ti en einai*) assumes center stage. The essence of a man, e.g., is the cause of certain matter constituting a man, namely, the soul. So form in the sense of essence is the primary substance of the *Metaphysics*. This is obviously not the primary substance of the *Categories* and, although the same word (*eidos*) is used, neither is this form the species of the *Categories*. The latter is treated in the *Metaphysics* as a kind of universal compound abstracted from particular compounds and appears to be denied substantial status.

While there is broad, though not universal, agreement that in the *Metaphysics* form is primary substance, there is equally broad disagreement over whether this is particular form, the form belonging to a single individual, or species form, the form common to all individuals in the species. There is also lively discussion concerning the relation of the *Metaphysics* doctrine of primary substance to the earlier doctrine of the *Categories*. Although a few scholars see an outright contradiction here, most take the divergence as evidence of the development of Aristotle's views on substance. Finally, the role of the central books in the *Metaphysics* as a whole continues to be debated. Some see them as an entirely self-contained analysis of form, others as preparatory to Book XII's discussion of non-sensible form and the role of the unmoved mover as the final cause of motion.

Practical philosophy. Two of Aristotle's most heralded works, the *Nicomachean Ethics* and the *Politics*, are treatises in practical philosophy. Their aim is effective action in matters of conduct. So they deal with what is up to us and can be otherwise because in this domain lie choice and action. The practical nature of ethics lies mainly in the development of a certain kind of agent. The *Nicomachean Ethics* was written, Aristotle reminds us, "not in order to know what virtue is, but in order to become good." One becomes good by becoming a good chooser and doer. This is not simply a matter of choosing and doing right actions but of choosing or doing them in the right way. Aristotle assumes that, for the most part, agents know what ought to be done (the evil or vicious person is an exception). The *akratic* or morally weak agent desires to do other than what he knows ought to be done and acts on this desire against his better judgment. The *enkratic* or morally strong person shares the akratic agent's desire but acts in accordance with his better judgment. In neither kind of choice are desire and judgment in harmony. In the virtuous, on the other hand, desire and judgment agree. So their choices and actions will be free of the conflict and pain that inevitably accompany those of the akratic and enkratic agent. This is because the part of their soul that governs choice and action is so disposed that desire and right judgment coincide. Acquiring a stable disposition (*hexis*) of this sort amounts to acquiring moral virtue (*ethike arete*). The disposition is concerned with choices as would be determined by the person of practical wisdom (*phronesis*); these will be actions lying between extreme alternatives. They will lie in a mean – popularly called the "golden mean" – relative to the talents and stores of the agent. Choosing in this way is not easily done. It involves, for instance, feeling anger or extending generosity at the right time, toward the right people, in the right way, and for the right reasons. Intellectual virtues, such as excellence at mathematics, can be acquired by teaching, but moral virtue cannot. I may know what ought to be done and even perform virtuous acts without being able to act *virtuously*. Nonetheless, because moral virtue is a disposition concerning choice, deliberate performance of virtuous acts can, ultimately, instill a disposition to choose them in harmony and with pleasure and, hence, to act virtuously.

Aristotle rejected Plato's transcendental Form of the Good as irrelevant to the affairs of persons and, in general, had little sympathy with the notion of an absolute good. The goal of choice and action is the human good, namely, living well. This, however, is not simply a matter of possessing the requisite practical disposition. Practical wisdom, which is necessary for living well, involves skill at calculating the best means to achieve one's ends and this is an intellectual virtue. But the ends that are presupposed by deliberation are established by moral virtue. The end of all action, the good for man, is happiness (*eudaimonia*). Most things, such as wealth, are valued only as a means to a worthy end. Honor, pleasure, reason, and individual virtues, such as courage and generosity, are deemed worthy in their own right but they can also be sought for the sake of eudaimonia. Eudaimonia alone can be sought only for its own sake. Eudaimonia is not a static state of the soul but a kind of activity (*energeia*) of the soul – something like human flourishing. The happy person's life will be self-sufficient and complete in the highest measure. The good for man, then, is activity in accordance with virtue or the highest virtue, should there be one. Here 'virtue' means something like excellence and applies to much besides man. The excellence of an ax lies in its cutting, that of a horse in its equestrian qualities. In short, a thing's excellence is a matter of how well it performs its characteristic functions or, we might say, how well it realizes its nature.

The natural functions of persons reside in the exercise of their natural cognitive faculties, most importantly the faculty of reason. So human happiness consists in activity in accordance with reason. However, persons can exercise reason in practical or in purely theoretical matters. The first suggests that happiness consists in the practical life of moral virtue, the second that it consists in the life of theoretical activity. Most of the *Nicomachean Ethics* is devoted to the moral virtues, but the final book appears to favor theoretical activity (*theoria*) as the highest and most choiceworthy end. It is man's closest approach to divine activity. Much recent scholarship is devoted to the relation between these two conceptions of the good, particularly to whether they are of equal value and whether they exclude or include one another.

Ethics and politics are closely connected. Aristotle conceives of the state as a natural entity arising among persons to serve a natural function. This is not merely, e.g., provision for the common defense or promotion of trade. Rather, the state of the *Politics* also has eudaimonia as its goal, namely, fostering the complete and self-sufficient lives of its citizens. Aristotle produced a complex taxonomy of constitutions but reduced them, in effect, to three kinds: monarchy, aristocracy, and democracy. Which best serves the natural end of a state was, to some extent, a relative matter for Aristotle. Although he appears to have favored democracy, in some circumstances monarchy might be appropriate.

The standard ordering of Aristotle's works ends with the *Rhetoric* and the *Poetics*. The *Rhetoric*'s extensive discussion of oratory or the art of persuasion locates it between politics and literary theory. The relatively short *Poetics* is devoted chiefly to the analysis of tragedy. It has had an enormous historical influence on aesthetic theory in general as well as on the writing of drama.

Arminianism. See ARMINIUS.

Arminius, Jacobus (1560–1609), Dutch theologian who, as a Dutch Reformed pastor and later professor at the University of Leiden, challenged Calvinist orthodoxy on predestination and free will. After his death, followers codified Arminius's views in a document asserting that God's grace is necessary for salvation, but not irresistible: the divine decree depends on human free choice. This became the basis for Arminianism, which was condemned by the Dutch Reformed synod but vigorously debated for centuries among Protestant theologians of different denominations. The term 'Arminian' is still occasionally applied to theologians who defend a free human response to divine grace against predestinationism. R.H.K.

Armstrong, David M. (1926–2014), Australian philosopher of mind and metaphysician, and until his retirement Challis Professor of Philosophy at Sydney, noted for his allegiance to a physicalist account of consciousness and to a realist view of properties conceived as universals. In *A Materialist Theory of the Mind* (1968), Armstrong develops a scientifically motivated version of the view that mental states are identical with physical states of the central nervous system. *Universals and Scientific Realism* (1978) and *What Is a Law of Nature?* (1983) argue that a scientifically adequate ontology must include universals in order to explain the status of natural laws. Armstrong contends that laws must be construed as involving relations of necessitation between universals rather than mere regularities among particulars. However, he is prepared to acknowledge the existence of only such universals as are required for the purposes of scientific explanation. Moreover, he adopts an 'immanent' or 'Aristotelian' (as opposed to a 'transcendent' or 'Platonic') realism, refusing to accept the existence of uninstantiated universals and denying that universals somehow exist 'outside' space and time.

More recently, Armstrong has integrated his scientifically inspired physicalism and property realism within the overall framework of an ontology of states of affairs, notably in *A World of States of Affairs* (1997). Here, and more fully in *Truth and Truthmakers* (2004), he advocates the truthmaker principle that every truth must be made true by some existing state of affairs and contends that states of affairs, rather than the universals and particulars that he regards as their constituents, are the basic building blocks of reality. Within this ontology, which in some ways resembles that of Wittgenstein's *Tractatus*, necessity and possibility are accommodated by appeal to combinatorial principles. As Armstrong explains in *A Combinatorial Theory of Possibility* (1989), this approach offers an ontologically economical alternative to the realist conception of possible worlds defended by David Lewis.

Arnauld, Antoine (1612–94), French theologian and philosopher, perhaps the most important and best-known intellectual associated with the Jansenist community at Port-Royal, as well as a staunch and orthodox champion of Cartesian philosophy. His theological writings defend the Augustinian doctrine of efficacious grace, according to which salvation is not earned by one's own acts, but granted by the irresistible grace of God. He also argues in favor of a strict contritionism, whereby one's absolution must be based on a true, heartfelt repentance, a love of God, rather than a selfish fear of God's punishment. These views brought him and Port-Royal to the center of religious controversy in seventeenth-century France, as Jansenism came to be perceived as a subversive extension of Protestant reform.

Arnauld was also constantly engaged in philosophical disputation, and was regarded as one of the sharpest and most philosophically acute thinkers of his time. His influence on several major philosophers of the period resulted mainly from his penetrating criticism of their systems. In 1641, Arnauld was asked to comment on Descartes's *Meditations*. The objections he sent – regarding, among other topics, the representational nature of ideas, the circularity of Descartes's proofs for the existence of God, and the apparent irreconcilability of Descartes's conception of material substance with the Catholic doctrine of Eucharistic transubstantiation – were considered by Descartes to be the most intelligent and serious of all. Arnauld offered his objections in a constructive spirit, and soon became an enthusiastic defender of Descartes's philosophy, regarding it as beneficial both to the advancement of human learning and to Christian piety. He insists, e.g., that the immortality of the soul is well grounded in Cartesian mind-body dualism.

In 1662, Arnauld composed (with Pierre Nicole) the *Port-Royal Logic*, an influential treatise on language and reasoning. After several decades of theological polemic, during which he fled France to the Netherlands, Arnauld resumed his public philosophical activities with the publication in 1683 of *On True and False Ideas* and in 1685 of *Philosophical and Theological Reflections on the New System of Nature and Grace*. These two works, opening salvos in what would become a long debate, constitute a detailed attack on Malebranche's theology and its philosophical foundations. In the first, mainly philosophical treatise, Arnauld insists that ideas, or the mental representations that mediate human knowledge, are nothing but acts of the mind that put us in direct cognitive and perceptual contact with things in the world. (Malebranche, as Arnauld reads him, argues that ideas are immaterial but non-mental objects in God's understanding that we know and perceive instead of physical things. Thus, the debate is often characterized as between Arnauld's direct realism and Malebranche's representative theory.) Such mental acts also have representational content, or what Arnauld (following Descartes) calls "objective reality." This content explains the act's intentionality, or directedness toward an object. Arnauld would later argue with Pierre Bayle, who came to Malebranche's defense, over whether *all* mental phenomena have intentionality, as Arnauld believes, or, as Bayle asserts, certain events in the soul (e.g., pleasures and pains) are non-intentional.

This initial critique of Malebranche's epistemology and philosophy of mind, however, was intended by Arnauld only as a prolegomenon to the more important attack on his theology; in particular, on Malebranche's claim that God always acts by general volitions and never by particular volitions. This view, Arnauld argues, undermines the true Catholic system of divine providence and threatens the efficacy of God's will by removing God from direct governance of the world.

In 1686, Arnauld also entered into discussions with Leibniz regarding the latter's *Discourse on Metaphysics*. In the ensuing correspondence, Arnauld focuses his critique on Leibniz's concept of substance and on his causal theory, the preestablished harmony. In this exchange, like the one with Malebranche, Arnauld is concerned to preserve what he takes to be the proper way to conceive of God's freedom and providence, although his remarks on substance (in which he objects to Leibniz's reintroduction of "substantial forms") are also clearly motivated by his commitment to a strict Cartesian ontology – bodies are nothing more than extension, devoid of any spiritual element. Most of his philosophical activity in the latter half of the century, in fact, is a vigorous defense of Cartesianism, particularly on theological grounds (e.g., demonstrating the consistency between Cartesian metaphysics and the Catholic dogma of real presence in the Eucharist), as it became the object of condemnation in both Catholic and Protestant circles.

arrow paradox. See ZENO'S PARADOXES.

Arrow's paradox, also called Arrow's (impossibility) theorem, a major result in social choice theory, named for its discoverer, economist Kenneth Arrow. It is intuitive to suppose that the preferences of individuals in a society can be expressed formally, and then aggregated into an expression of social preferences, a social choice function. Arrow's paradox is that individual preferences having certain well-behaved formalizations demonstrably cannot be aggregated into a similarly well-behaved social choice function satisfying four plausible formal conditions: (1) collective rationality – any set of individual orderings and alternatives must yield a social ordering; (2) Pareto optimality – if all individuals prefer one ordering to another, the social ordering must also agree; (3) non-dictatorship – the social ordering must not be identical to a particular individual's ordering; and (4) independence of irrelevant alternatives – the social ordering depends on no properties of the individual orderings other than the orders themselves, and for a given set of alternatives it depends only on the orderings of those particular alternatives.

Most attempts to resolve the paradox have focused on aspects of (1) and (4). Some argue that preferences can be rational even if they are intransitive. Others argue that cardinal orderings, and hence interpersonal comparisons of preference intensity, are relevant.

artifact, an object intentionally made or produced for a certain purpose. In a more restricted sense, the term designates simple objects, such as tools, which represent a particular culture. In anthropological literature the word is sometimes used for *any* objects produced by human activities, including various by-products (residue or "debitage"). Objects taken from their natural environment and used for some purpose without modification – sometimes called *naturefacts* – form a bridge between natural objects and artifacts. Naturefacts are a subclass of *ecofacts* – i.e., unmodified non-artifactual objects and materials relevant to interpreting an archaeological site.

On the definition given here, the concept of *artifact* is equivalent to that of *work* (as product), and *artifact* and *author* are correlative concepts: objects are artifacts if and only if they have authors (makers). Artifacts include artworks and literary compositions. Ontologically, an artifact can be a concrete object such as a ship; a type (e.g., the dollar bill); an instance of a type (an individual dollar bill); or an abstract object, say, an artificial language. A singular artifact can ontologically depend on its foundation. The St. Gotthard rail tunnel, e.g. (made to facilitate traffic between Switzerland and Italy), depends on the St. Gotthard Massif mountain range.

Artifacts are classified variously: e.g., by their form, appearance, method of manufacture, material properties, style, or intended use. Complex artifacts are usually made by joining objects; this is *assembly* or *conjunction* (e.g., making a knife by attaching a handle to a blade). Given a number of productive action-types $A_1, \ldots, A_n$, an artifact can be defined quasi-inductively as an object intentionally produced from some natural or artificial "parent" object or objects by means the actions A_i ($i = 1, \ldots, n$).

artificial intelligence, also called AI, the scientific effort to design and build intelligent artifacts. Since the effort inevitably presupposes and tests theories about the nature of intelligence, it has implications for the philosophy of mind – perhaps even more than does empirical psychology. For one thing, actual construction amounts to a direct assault on the mind-body problem; should it succeed, some form of materialism would seem to be vindicated. For another, a working model, even a limited one, requires a more global conception of what intelligence is than do experiments to test specific hypotheses. In fact, psychology's own overview of its domain has been much influenced by fundamental concepts drawn from AI.

Although the idea of an intelligent artifact is old, serious scientific research dates only from the 1950s, and is associated with the development of programmable computers. Intelligence is understood as a *structural property* or capacity of an active system; i.e., it does not matter what the system is made of, as long as its parts and their interactions yield intelligent behavior overall. For instance, if solving logical problems, playing chess, or conversing in English manifests intelligence, then it is not important whether the "implementation" is electronic, biological, or mechanical, just as long as it solves, plays, or talks. Computers are relevant mainly because of their flexibility and economy: software systems are unmatched in achievable active complexity per invested effort.

Despite the generality of programmable structures and the variety of historical approaches to the mind, the bulk of AI research divides into two broad camps – which we can think of as *language-oriented* and *pattern-oriented*, respectively. Conspicuous by their absence are significant influences from the conditioned-response paradigm, the psychoanalytic tradition, the mental picture idea, empiricist (atomistic) associationism, and so on. Moreover, both AI camps tend to focus on cognitive issues, sometimes including perception and motor control. Notably omitted are such psychologically important topics as affect, personality, aesthetic and moral judgment, conceptual change, mental illness, etc. Perhaps such matters are beyond the purview of artificial *intelligence;* yet it is an unobvious substantive thesis that intellect can be cordoned off and realized independently of the rest of human life.

The two main AI paradigms emerged together in the 1950s (along with cybernetic and information-theoretic approaches, which turned out to be dead ends); and both are vigorous today. But for most of the sixties and seventies, the language-based orientation dominated attention and funding, for three signal reasons. First, computer data structures and processes themselves seemed language-like: data were syntactically and semantically articulated, and processing was localized (serial). Second, twentieth-century linguistics and logic made it intelligible that and how such systems might work: automatic symbol manipulation made clear, powerful sense. Finally, the sorts of performance most amenable to the approach – explicit reasoning and "figuring out" – strike both popular and educated opinion as particularly "intellectual"; hence, early successes were all the more impressive, while "trivial" stumbling blocks were easier to ignore.

The basic idea of the linguistic or *symbol manipulation* camp is that thinking is like talking – inner discourse – and, hence, that thoughts are like sentences. The suggestion is venerable; and Hobbes even linked it explicitly to computation. Yet it was a major scientific achievement to turn the general idea into a serious theory. The account does not apply only, or even especially, to the sort of thinking that is accessible to conscious reflection. Nor is the "language of thought" supposed to be much like English, predicate logic, LISP, or any other familiar notation; rather, its detailed character is an empirical research problem. And, despite fictional stereotypes, the aim is not to build superlogical or inhumanly rational automata. Our human tendencies to take things for granted, make intuitive leaps, and resist implausible conclusions are not weaknesses that AI strives to overcome but abilities integral to real intelligence that AI aspires to share.

In what sense, then, is thought supposed to be language-like? Three items are essential. First, thought tokens have a combinatorial syntactic structure; i.e., they are compounds of well-defined atomic constituents in well-defined (recursively specifiable) arrangements. So the constituents are analogous to words, and the arrangements are analogous to phrases and sentences; but there is no supposition that they should resemble any known words or grammar. Second, the contents of thought tokens, what they "mean," are a systematic function of their composition: the constituents and forms of combination have determinate significances that together determine the content of any well-formed compound. So this is like the meaning of a sentence being determined by its grammar and the meanings of its words. Third, the intelligent progress or sequence of thought is specifiable by rules expressed syntactically – they can be carried out by processes sensitive only to syntactic properties. Here the analogy is to proof theory: the formal validity of an argument is a matter of its according with rules expressed formally. But this analogy is particularly treacherous, because it immediately suggests the rigor of logical inference; but, if intelligence is specifiable by formal rules, these must be far more permissive, context-sensitive, and so on, than those of formal logic.

Syntax as such is perfectly neutral as to how the constituents are identified (by sound, by shape, by magnetic profile) and arranged (in time, in space, via address pointers). It is, in effect, a free parameter: whatever can serve as a bridge between the semantics and the processing. The account shares with many others the assumptions that thoughts are contentful (meaningful) and that the processes in which they occur can somehow be realized physically. It is distinguished by the two further theses that there must be some independent way of describing these thoughts that mediates between (simultaneously determines) their contents and how they are processed, and that, so described, they are combinatorially structured. Such a description is *syntactical*.

We can distinguish two principal phases in language-oriented AI, each lasting about twenty years. Very roughly, the first phase emphasized processing (search and reasoning), whereas the second has emphasized representation (knowledge). To see how this went, it is important to appreciate the intellectual breakthrough required to conceive AI at all. A machine, such as a computer, is a deterministic system, except for random elements. That is fine for perfectly constrained domains, like numerical calculation, sorting, and parsing, or for domains that are constrained except for prescribed randomness, such as statistical modeling. But, in the general case, intelligent behavior is neither perfectly constrained nor perfectly constrained with a little random variation thrown in. Rather, it is generally focused and sensible, yet also fallible and somewhat variable. Consider, e.g., chess playing (an early test bed for AI): listing all the legal moves for any given position is a perfectly constrained problem, and easy to program; but choosing the best move is not. Yet an intelligent player does not simply determine which moves would be legal and then choose one randomly; intelligence in chess play is to choose, if not always the best, at least usually a good move. This is something between perfect determinacy and randomness, a "between" that is not simply a mixture of the two. How is it achievable in a machine?

The crucial innovation that first made AI concretely and realistically conceivable is that of a *heuristic procedure*. (The term 'heuristic' derives from the Greek word for discovery, as in Archimedes' exclamation "Eureka!") The relevant point for AI is that discovery is a matter neither of following exact directions to a goal nor of dumb luck, but of looking around sensibly, being guided as much as possible by what you know in advance and what you find along the way. So a heuristic procedure is one for sensible discovery, a procedure for sensibly guided search. In chess, e.g., a player does well to bear in mind a number of rules of thumb: other things being equal, rooks are more valuable than knights, it is an asset to control the center of the board, and so on. Such guidelines, of course, are not valid in every situation; nor will they all be best satisfied by the same move. But, by following them while searching as far ahead through various scenarios as possible, a player can make generally sensible moves – much better than random – within the constraints of the game. This picture even accords fairly well with the introspective feel of choosing a move, particularly for less experienced players.

The essential insight for AI is that such rough-and-ready (*ceteris paribus*) rules can be deterministically programmed. It all depends on how you look at it. One and the same bit of computer program can be, from one point of view, a deterministic, infallible procedure for computing how a given move would change the relative balance of pieces, and from another, a generally sensible but fallible procedure for estimating how "good" that move would be. The substantive thesis about intelligence – human and artificial alike – then is that our powerful but fallible ability to form "intuitive" hunches, educated guesses, etc., is the result of (largely unconscious) search, guided by such heuristic rules.

The second phase of language-inspired AI, dating roughly from the mid-1970s, builds on the idea of heuristic procedure, but dramatically changes the emphasis. The earlier work was framed by a conception of intelligence as *finding* solutions to problems (e.g., good moves). From such a perspective, the specification of the problem (the rules of the game plus the current position) and the provision of some heuristic guides (domain-specific rules of thumb) are merely a setting of the parameters; the real work, the real exercise of intelligence, lies in the intensive guided search undertaken in the specified terms. The later phase, impressed not so much by our problem-solving prowess as by how well we get along with "simple" common sense, has shifted the emphasis from search and reasoning to knowledge.

The motivation for this shift can be seen in the following two sentences:

> We gave the monkey the banana because it was ripe.
> We gave the monkey the banana because it was hungry.

The word 'it' is ambiguous, as the terminal adjectives make clear. Yet listeners effortlessly understand what is meant, to the point, usually, of not even noticing the ambiguity. The question is, how? Of course, it is "just common sense" that monkeys don't get ripe and bananas don't get hungry, so . . . But three further observations show that this is not so much an answer as a restatement of the issue. First, sentences that rely on common sense to avoid misunderstanding are anything but rare: conversation is rife with them. Second, just about any odd fact that "everybody knows" can be the bit of common sense that understanding the next sentence depends on; and the range of such knowledge is vast. Yet, third, dialogue proceeds in real time without a hitch, almost always. So the whole range of commonsense knowledge must be somehow at our mental fingertips all the time.

The underlying difficulty is not with speed or quantity alone, but with *relevance*. How does a system, given all that it knows about aardvarks, Alabama, and ax handles, "home in on" the pertinent fact that bananas don't get hungry, in the fraction of a second it can afford to spend on the pronoun 'it'? The answer proposed is both simple and powerful: common sense is not just randomly stored information, but is instead highly organized by topics, with lots of indexes, cross-references, tables, hierarchies, etc. The words in the sentence itself trigger the "articles" on monkeys, bananas, hunger, etc., and these quickly reveal that monkeys are mammals, hence animals, that bananas are fruit, hence from plants, that hunger is what animals feel when they need to eat – and that settles it. The amount of search and reasoning is minimal; the issue of relevance is solved instead by the antecedent *structure* in the stored knowledge itself. While this requires larger and more elaborate systems, the hope is that it will make them faster and more flexible.

The other main orientation toward artificial intelligence, the pattern-based approach – often called "connectionism" or "parallel distributed processing" – reemerged from the shadow of symbol processing only in the 1980s, and remains in many ways less developed. The basic inspiration comes not from language or any other psychological phenomenon (such as imagery or affect), but from the microstructure of the brain. The components of a connectionist system are relatively simple active nodes – *lots* of them – and relatively simple connections between those nodes – again, *lots* of them. One important type (and the easiest to visualize) has the nodes divided into layers, such that each node in layer *A* is connected to each node in layer *B*, each node in layer *B* is connected to each node in layer *C*, and so on. Each node has an activation level, which varies in response to the activations of other, connected nodes; and each connection has a weight, which determines how strongly (and in what direction) the activation of one node affects that of the other. The analogy with neurons and synapses, though imprecise, is intended.

So imagine a layered network with finely tuned connection weights and random (or zero) activation levels. Now suppose the activations of all the nodes in layer *A* are set in some particular way – some pattern is imposed on the activation state of this layer. These activations will propagate out along all the connections from layer *A* to layer *B*, and activate some pattern there. The activation of *each* node in layer *B* is a function of the activations of *all* the nodes in layer *A*, and of the weights of all the connections to it from those nodes. But since each node in layer *B* has its own connections from the nodes in layer *A*, it will respond in its own unique way to this pattern of activations in layer *A*. Thus, the *pattern* that results in layer *B* is a joint function of the pattern that was imposed on layer *A* and of the pattern of connection weights between the two layers. And a similar story can be told about layer *B*'s influence on layer *C*, and so on, until some final pattern is induced in the last layer.

What are these patterns? They might be any number of things; but two general possibilities can be distinguished. They might be tantamount to (or substrata beneath) representations of some familiar sort, such as sentence-like structures or images; or they might be a kind (or kinds) of representation previously unknown. Now, people certainly do sometimes think in sentences (and probably images); so, to the extent that networks are taken as complete brain models, the first alternative must be at least partly right. But, to that extent, the models are also more physiological than psychological: it is rather the implemented sentences or images that directly model the mind. Thus, it is the possibility of a new genus of representation – sometimes called *distributed* representation – that is particularly exciting. On this alternative, the patterns in the mind represent in some way other than by mimetic imagery or articulate description. How?

An important feature of all network models is that there are two quite different categories of pattern. On the one hand, there are the relatively ephemeral patterns of activation in various groups of nodes; on the other, there are the relatively stable patterns of connection strength among the nodes. Since there are in general many more connections than nodes, the latter patterns are richer; and it is they that determine the capabilities of the network with regard to the former patterns. Many of the abilities most easily and "naturally" realized in networks can be subsumed under the heading *pattern completion:* the connection weights are adjusted – perhaps via a training regime – such that the network will *complete* any of the activation patterns from a predetermined group. So suppose some fraction (say half) of the nodes in the net are clamped to the values they would have for one of those patterns (say *P*) while the remainder are given random (or default) activations. Then the network, when run, will reset the latter activations to the values belonging to *P* – thus "completing" it. If the unclamped activations are regarded as variations or deviations, pattern completion amounts to *normalization*, or grouping by *similarity*. If the initial or input nodes are always the same (as in layered networks), then we have pattern *association* (or transformation) from input to output. If the input pattern is a memory probe, pattern completion becomes access by *content*. If the output pattern is an identifier, then it is pattern *recognition*. And so on. Note that, although the operands are activation patterns, the "knowledge" about them, the ability to complete them, is contained in the connection patterns; hence, that ability or know-how is what the network represents.

There is no obvious upper bound on the possible refinement or intricacy of these pattern groupings and associations. If the input patterns are sensory stimuli and the output patterns are motor control, then we have a potential model of coordinated and even skillful behavior. In a system *also* capable of language, a network model (or component) might account for verbal recognition and content association, and even such "nonliteral" effects as trope and tone. Yet at least some sort of "symbol manipulation" seems essential for language use, regardless of how network-like the implementation is. One current speculation is that it might suffice to approximate a battery of symbolic processes as a special subsystem within a cognitive system that fundamentally works on quite different principles.

The attraction of the pattern-based approach is, at this point, not so much actual achievement as it is promise – on two grounds. In the first place, the space of possible models, not only network topologies but also ways of construing the patterns, is vast. Those built and tested so far have been, for practical reasons, rather small; so it is possible to hope beyond their present limitations to systems of significantly greater capability. But second, and perhaps even more attractive, those directions in which pattern-based systems show the most promise – skills, recognition, similarity, and the like – are among the areas of greatest frustration for language-based AI. Hence it remains possible, for a while at least, to overlook the fact that, to date, no connectionist network can perform long division, let alone play chess or solve symbolic logic problems.

artificial language. See FORMAL LANGUAGE, PHILOSOPHY OF LANGUAGE.

artificial life, an interdisciplinary science studying the most general character of the fundamental processes of life. These processes include self-organization, self-reproduction, learning, adaptation, and evolution. Artificial life (or ALife) is to theoretical biology roughly what artificial intelligence (AI) is to theoretical psychology – computer simulation is the methodology of choice. In fact, since the mind exhibits many of life's fundamental properties, AI could be considered a subfield of ALife. However, whereas most traditional AI models are serial systems with complicated, centralized controllers making decisions based on global state information, most natural systems exhibiting complex autonomous behavior are parallel, distributed networks of simple entities making decisions based solely on their local state information, so typical ALife models have a corresponding distributed architecture.

A computer simulation of evolving "bugs" can illustrate what ALife models are like. Moving around in a two-dimensional world periodically laden with heaps of "food," these bugs eat, reproduce, and sometimes perish from starvation. Each bug's movement is genetically determined by the quantities of food in its immediate neighborhood, and random mutations and crossovers modify these genomes during reproduction. Simulations started with random genes show spontaneous waves of highly adaptive genetic novelties continuously sweeping through the population at precisely quantifiable rates (see C. Langston et al., eds., *Artificial Life II*, 1991).

ALife science raises and promises to inform many philosophical issues, such as: Is functionalism the right approach toward life? When, if ever, is a *simulation* of life *really alive?* When do systems exhibit the spontaneous emergence of properties?

ascriptivism, the theory that to call an action voluntary is not to describe it as caused in a certain way by the agent who did it, but to express a commitment to hold the agent responsible for the action. Ascriptivism is thus a kind of noncognitivism as applied to judgments about the voluntariness of acts. Introduced by Hart in "Ascription of Rights and Responsibilities," *Proceedings of the Aristotelian Society* (1949), ascriptivism was given its name and attacked in Geach's "Ascriptivism," *Philosophical Review* (1960). Hart recanted in the Preface to his *Punishment and Responsibility* (1968).

assertion, a speech act whereby the speaker puts forward a proposition as true or, secondarily, the proposition affirmed in such an act. The main vehicle for making assertions is the declarative sentence, spoken or written. Assertion is the default value of a declarative utterance or inscription. Assertion's conjugate is *questioning*. A question is a prompt to assertion, and a correct assertion answers the question. The point of assertion is *persuasion*, and if all goes well, by asserting that *P*, you persuade your audience that *P*.

Assertion is fundamental to human social life. It is our primary means of sharing our knowledge with others. It is critical to planning and coordinating behavior. There are clear antecedents of assertion in non-human animals, namely signaling behavior, but it is controversial whether such forms of communication count as genuine assertions. Some argue that assertion occurs only when appropriate conventions are antecedently in place. For example, perhaps the declarative mood is a convention in virtue of which we are able to assert.

Assertions have a word-to-world direction of fit: if the world isn't the way the assertion says it is, then the assertion is false and therefore bad *qua* assertion. This is true of other common speech acts as well. Guesses, conjectures, hypotheses, predictions, and guarantees all have a word-to-world direction of fit too. What individuates assertion within this group? The best answer is that assertion is individuated normatively and the "norm of assertion" is knowledge. On this view, known as *the knowledge account of assertion*, the speech act of assertion is constituted by a rule which enjoins us to assert *P* only if we know that *P* is true. The best evidence for the knowledge account of assertion is an explanatory argument from linguistic patterns. Everywhere we look, assertion and knowledge are linked. A natural way to get someone to tell you whether *P* is to ask, 'Do you know whether *P*?' Ordinarily an appropriate response to an assertion is to ask, 'How do you know?' And a natural way to avoid answering a direct question is to say, 'Sorry, I don't know the answer'. J.T.

associationism, the psychological doctrine that association is the sole or primary basis of learning as well as of intelligent thought and behavior. Association occurs when one type of thought, idea, or behavior follows, or is contingent upon, another thought, idea, or behavior or external event, and the second somehow bonds with the first. If the idea of eggs is paired with the idea of ham, then the two ideas may become associated. Associationists argue that complex states of mind and mental processes can be analyzed into associated elements. The complex may be novel, but the elements are products of past associations. Associationism often is combined with hedonism. Hedonism explains why events associate or bond: bonds are forged by pleasant experiences. If the pleasantness of eating eggs is combined with the pleasantness of eating ham, then ideas of ham and eggs associate. Bonding may also be explained by various non-hedonistic principles of association, as in Hume's theory of the association of ideas. One of these principles is contiguity in place or time.

Associationism contributes to the componential analysis of intelligent, rational activity into non-intelligent, non-rational, mechanical processes. People believe as they do, not because of rational connections among beliefs, but because beliefs associatively bond. Thus one may think of London when thinking of England, not because one possesses an inner logic of geographic beliefs from which one infers that London is in England. The two thoughts may co-occur because of contiguity or other principles.

Kinds of associationism occur in behaviorist models of classical and operant conditioning. Certain associationist ideas, if not associationism itself, appear in connectionist models of cognition, especially the principle that contiguities breed bonding. Several philosophers and psychologists, including Hume, Hartley, and J. S. Mill among philosophers and E. L. Thorndike (1874–1949) and B. F. Skinner (1904–90) among psychologists, are associationists.

Astell, Mary (1666–1731), an early English feminist and author of *A Serious Proposal to the Ladies* (1694 and 1697) and *Some Reflections on Marriage* (1700). These works argue that women's shortcomings are not due to a lack of intellectual ability, since women have rational souls, and present an educational program to fit them rationally for their religious duties. Astell entered as well into the philosophical, theological, and political controversies of her day. Her *Letters Concerning the Love of God* (1695) is a correspondence with the English Malebranchian John Norris over such issues as Norris's contention that our duty is to God only. Her most substantial work, *The Christian Religion, as Professed by a Daughter of the Church of England* (1705), lays out her views on the grounds and implications of natural and revealed religion. This work includes considerable critical attention to Locke's ideas, and both this and the *Letters* called forth refutations from Locke's friend, Damaris Cudworth.

Athanasius (c.297–373), early Christian father, bishop in Alexandria (though frequently exiled), and a leading protagonist in the fourth-century disputes concerning Christ's relationship to God. Through major works like *On the Incarnation, Against the Arians*, and *Letters on the Holy Spirit*, Athanasius contributed greatly to the classical doctrines of the Incarnation and the Trinity. Opposing all forms of Arianism, which denied Christ's divinity and reduced him to a creature, Athanasius taught, in the language of the Nicene Creed, that Christ the Son, and likewise the Holy

Spirit, were of the same being as God the Father (*homoousios*). Thus with terminology and concepts drawn from Greek philosophy, he helped to forge the distinctly Christian and un-Hellenistic doctrine of the eternal triune God, who became enfleshed in time and matter and restored humanity to immortality, forfeited through sin, by involvement in its condition of corruption and decay. **See also** **ARIANISM.** A.E.L.

atheism (from Greek *a*-, 'not', and *theos*, 'god'), the view that there are no gods. A widely used sense denotes merely not believing in god and is consistent with agnosticism. A stricter sense denotes a belief that there is no god; this use has become standard. In the *Apology* Socrates is accused of atheism for not believing in the official Athenian gods. Some distinguish between *theoretical atheism* and *practical atheism*. A theoretical atheist self-consciously denies the existence of a supreme being, whereas a practical atheist may believe that a supreme being exists but lives as though there were no god. L.P.P.

atonement, the state of being at one or reconciled; in its main sense, the means by which such reconciliation is achieved and, more specifically, the sacrificial act by which such reconciliation is achieved. All this implies that the parties to be reconciled are initially estranged from each other.

Some Christian theologians think Christ's sacrifice includes his life, but most think it especially involves his suffering and death. In Christian theology, our sin estranges us from God, and Christ's sacrifice is a necessary part of a sufficient condition that cancels such sin. There are, however, different theories as to how Christ's sacrifice does this. Historically, there are at least three main theories. The *ransom theory* says that our sin enslaves us to the Devil, and Christ's sacrifice ransoms us from slavery. The *satisfaction theory*, associated with Anselm, says that our sin incurs a debt to God, and Christ, by his sacrifice, compensates God, in our place, for the debt. The *penal substitution theory* says that, on account of our sin, we deserve to be punished, and Christ, by his sacrifice, is punished in our place. These theories are not exclusive, and one may combine some or all of them.

attribution theory, a theory in social psychology concerned with how and why ordinary people explain events. People explain by attributing causal powers to certain events rather than others. The theory attempts to describe and clarify everyday commonsense explanation, to identify criteria of explanatory success presupposed by common sense, and to compare and contrast commonsense explanation with scientific explanation. The heart of attribution theory is the thesis that people tend to attribute causal power to factors personally important to them, which they believe covary with alleged effects. For example, a woman may designate sexual discrimination as the cause of her not being promoted in a corporation. Being female is important to her and she believes that promotion and failure covary with gender. Males get promoted; females don't. Causal attributions tend to preserve self-esteem, reduce cognitive dissonance, and diminish the attributor's personal responsibility for misdeeds. When attributional styles or habits contribute to emotional ill-being, e.g. to chronic, inappropriate feelings of depression or guilt, attribution theory offers the following therapeutic recommendation: change attributions so as to reduce emotional ill-being and increase well-being. Hence if the woman blames herself for the failure, and if self-blame is part of her depressive attributional style, she would be encouraged to look outside herself, perhaps to sexual discrimination, for the explanation. **See also** EXPLANATION, MOTIVATIONAL EXPLANATION. Audi, Robert (b.1941), American philosopher known for a comprehensive theory of reasons and rationality, an epistemologically sophisticated intuitionist theory in ethics, a liberal theory of the relation between religion and politics, and distinctive accounts of belief, desire, intention, and practical reasoning. An overarching aim of much of his work is to defend a non-skeptical theory of rationality and to account for how theoretical and practical rationality combine in determining the overall rationality of a person – "global rationality" (*The Architecture of Reason*, 2001). In epistemology, Audi combines internalism about justification with externalism about knowledge, both justification and knowledge being structurally foundational. He considers the basic sources of justification broadly experiential, but in a way that accommodates a priori knowledge, for which he takes self-evidence as basic (*The Structure of Justification*, 1993; *Epistemology*, 3d ed. 2010). Audi extends his epistemological theory to philosophy of religion, particularly the relation between reason and faith (*Rationality and Religious Commitment*, 2011); social epistemology, centering on a theory of testimony; and ethics, with moral epistemology as a major element.

Audi is highly prominent in the revival of ethical intuitionism understood as including an account of moral knowledge and a pluralist moral theory of the sort defended by Ross. But Audi has developed the view far beyond Ross and the classical intuitionists. Audi's moral epistemology combines an account of a priori knowledge of moral principles with a theory of moral perception that addresses the possibility of knowledge of particular moral facts such as the injustice of specific acts (*Moral Knowledge and Ethical Character*, 1997; *Moral Perception*, 2013). His normative moral theory, like Ross's, features a plurality of principles of prima facie duty, although, unlike Ross, Audi argues that such principles, though self-evident and knowable a priori, can be rationalized by a liberal interpretation he offers of the humanity formula of Kant's categorical imperative. The result is a unified Kantian intuitionism that avoids charges of dogmatism and arbitrariness often leveled against older versions of intuitionism (*The Good in the Right*, 2004).

In philosophy of mind and action, Audi has developed accounts of acting for reasons, freedom and compulsion, self-deception, weakness of will, and related notions. Each account is guided by the conviction that plausible views of these should be psychologically realistic in positing mental states and processes, in order to avoid, for instance, over-ascription of inferences and propositional attitudes in explicating justification, knowledge, and rational action (*Action, Intention, and Reason*, 1993).

Augustine, Saint, known as Augustine of Hippo (354–430), Christian philosopher, church father, and one of the chief sources of Christian thought in the West. His importance for medieval and modern European philosophy is impossible to describe briefly. Matters are made more difficult because Augustine wrote voluminously and dialectically as a Christian theologian, treating philosophical topics for the most part only as they were helpful to theology – or as corrected by it. He fashioned the narrative of the *Confessions* (397–400) out of the events of the first half of his life. He thus supplied later biographers with both a seductive selection of biographical detail and a compelling story of his successive conversions from adolescent sensuality, to the image-laden religion of the Manichaeans, to a version of Neoplatonism, and then to Christianity. The story is an unexcelled introduction to Augustine's views of philosophy. It shows, for instance, that Augustine received very little formal education in philosophy. He was trained as a rhetorician, and the only philosophical work that he mentions among his early reading is Cicero's (lost) *Hortensius*, an exercise in persuasion to the study of philosophy. Again, the narrative makes plain that Augustine finally rejected Manichaeanism because he came to see it as bad philosophy: a set of sophistical fantasies without rational coherence or explanatory force. More importantly, Augustine's final conversion to Christianity was prepared by his reading in "certain books of the Platonists" (*Confessions* 7.9.13). These Latin translations, which seem to have been anthologies or manuals of philosophic teaching, taught Augustine a form of Neoplatonism that enabled him to conceive of a cosmic hierarchy descending from an immaterial, eternal, and intelligible God. On Augustine's judgment, philosophy could do no more than that; it could not give him the power to order his own life so as to live happily and in a stable relation with the now-discovered God. Yet in his first years as a Christian, Augustine took time to write a number of works in philosophical genres. Best known among them are a refutation of Academic Skepticism (*Contra academicos*, 386), a theodicy (*De ordine*, 386), and a dialogue on the place of human choice within the providentially ordered hierarchy created by God (*De libero arbitrio*, 388/391–95).

Within the decade of his conversion, Augustine was drafted into the priesthood (391) and then consecrated bishop (395). The thirty-five years of his life after that consecration were consumed by labors on behalf of the church in northern Africa and through the Latin-speaking portions of the increasingly fragmented empire. Most of Augustine's episcopal writing was polemical both in origin and in form; he composed against authors or movements he judged heretical, especially the Donatists and Pelagians. But Augustine's sense of his authorship also led him to write works of fundamental theology conceived on a grand scale. The most famous of these works, beyond the *Confessions*, are *On the Trinity* (399–412, 420), *On Genesis According to the Letter* (401–15), and *On the City of God* (413–26). *On the Trinity* elaborates in subtle detail the distinguishable "traces" of Father, Son, and Spirit in the created world and particularly in the human soul's triad of memory, intellect, and will. The commentary on Genesis 1–3, which is meant to be much more than a "literal" commentary in the modern sense, treats many topics in philosophical psychology and anthropology. It also teaches such cosmological doctrines as the "seed-reasons" (*rationes seminales*) by which creatures are given intelligible form. The *City of God* begins with a critique of the bankruptcy of pagan civic religion and its attendant philosophies, but it ends with the depiction of human history as a combat between forces of self-love, conceived as a diabolic city of earth, and the graced love of God, which founds that heavenly city within which alone peace is possible.

A number of other, discrete doctrines have been attached to Augustine, usually without the dialectical nuances he would have considered indispensable. One such doctrine concerns divine "illumination" of the human intellect – i.e., some active intervention by God in ordinary processes of human understanding. Another doctrine typically attributed to Augustine is the inability of the human will to do morally good actions without grace. A more authentically Augustinian teaching is that introspection or inwardness is the way of discovering the created hierarchies by which to ascend to God. Another authentic teaching would be that time, which is a distension of the divine "now," serves as the medium or narrative structure for the creation's return to God. But no list of doctrines or positions, however authentic or inauthentic, can serve as a faithful representation of Augustine's thought, which gives itself only through the carefully wrought rhetorical forms of his texts.

Aurelius, Marcus. See MARCUS AURELIUS, STOICISM.

Austin, John (1790–1859), English legal philosopher known especially for his command theory of law. His career as a lawyer was unsuccessful but his reputation as a scholar was such that on the founding of University College, London, he was offered the chair of jurisprudence. In 1832 he published the first ten of his lectures, compressed into six as *The Province of Jurisprudence Determined*. Although he published a few papers, and his somewhat fragmentary *Lectures on Jurisprudence* (1863) was published posthumously, it is on the *Province* that his reputation rests. He and Bentham (his friend, London neighbor, and fellow utilitarian) were the foremost English legal philosophers of their time, and their influence on the course of legal philosophy endures.

Austin held that the first task of legal philosophy, one to which he bent most of his energy, is to make clear what laws are, and if possible to explain why they are what they are: their rationale. Until those matters are clear, legislative proposals and legal arguments can never be clear, since irrelevant considerations will inevitably creep in. The proper place for moral or theological considerations is in discussion of what the positive law ought to be, not of what it is. Theological considerations reduce to moral ones, since God can be assumed to be a good utilitarian. It is positive laws, "that is to say the laws which are simply and strictly so called, . . . which form the appropriate matter of general and particular jurisprudence." They must also be distinguished from "laws metaphorical or figurative."

A *law in its most general sense* is "a rule laid down for the guidance of an intelligent being by an intelligent being having power over him." It is a command, however phrased. It is the commands of men to men, of political superiors, that form the body of positive law. General or comparative jurisprudence, the source of the rationale, if any, of particular laws, is possible because there are commands nearly universal that may be attributed to God or Nature, but they become positive law only when laid down by a ruler. The general model of an Austinian analytic jurisprudence built upon a framework of definitions has been widely followed, but cogent objections, especially by Hart, have undermined the command theory of law.

See also JURISPRUDENCE, PHILOSOPHY OF LAW. E.L.P.

Austin, J(ohn) L(angshaw) (1911–60), English philosopher, a leading exponent of postwar "linguistic" philosophy. Educated primarily as a classicist at Shrewsbury and Balliol College, Oxford, he taught philosophy at Magdalen College. During World War II he served at a high level in military intelligence, which earned him the O.B.E., Croix de Guerre, and Legion of Merit. In 1952 he became White's Professor of Moral Philosophy at Oxford, and in 1955 and 1958 he held visiting appointments at Harvard and Berkeley, respectively. In his relatively brief career, Austin published only a few invited papers; his influence was exerted mainly through discussion with his colleagues, whom he dominated more by critical intelligence than by any preconceived view of what philosophy should be.

Unlike some others, Austin did not believe that philosophical problems all arise out of aberrations from "ordinary language," nor did he necessarily find solutions there; he dwelled, rather, on the authority of the vernacular as a source of nice and pregnant distinctions, and held that it deserves much closer attention than it commonly receives from philosophers. It is useless, he thought, to pontificate at large about knowledge, reality, or existence, e.g., without first examining in detail how, and when, the words 'know', 'real', and 'exist' are employed in daily life. In *Sense and Sensibilia* (1962; compiled from lecture notes), the sense-datum theory comes under withering fire for its failings in this respect. Austin also provoked controversy with his well-known distinction between "performative" and "constative" utterances ('I promise' *makes* a promise, whereas 'he promised' merely reports one); he later recast this as a threefold differentiation of locutionary, illocutionary, and perlocutionary "forces" in utterance, corresponding (roughly) to the meaning, intention, and consequences of saying a thing, in one context or another. Though never very stable or fully worked out, these ideas have since found a place in the still-evolving study of speech acts.

See also ORDINARY LANGUAGE PHILOSOPHY, SPEECH ACT THEORY. P.He.

Australasian philosophy, the philosophical work produced mainly by Australian and New Zealand philosophers largely since World War II. Australasian philosophy has been known especially for its blend of analytical empiricism, logic, and realism – applied uncompromisingly to central questions in metaphysics, ethics, epistemology, philosophy of science, philosophy of mind, and more.

For example, in the 1950s, U. T. Place ("Is Consciousness a Brain Process?" 1956) and J. J. C. Smart ("Sensations and Brain Processes," 1959) identified the mental with the physical. The result is still called "Australian materialism." D. M. Armstrong (*A Materialist Theory of the Mind*, 1968) built upon that base. Australian philosophy has challenged that materialism, too. Frank Jackson ("Epiphenomenal Qualia," 1982) asked whether one could know everything physical about color without having whatever knowledge arises from experiencing color. David Chalmers (*The Conscious Mind*, 1996) confronted materialism with the conceivability of zombies – physical beings functionally equivalent to human beings but lacking consciousness. Functionalism – a target of Chalmers's criticism – has been represented by David Braddon-Mitchell and Jackson (*Philosophy of Mind and Cognition*, 1996/2007); and consciousness is receiving much attention from Australian philosophers, for instance Chalmers (*The Character of Consciousness*, 2010) and Daniel Stoljar (*Ignorance and Imagination*, 2006).

In addition to that concern with mental properties, Australian philosophers have discussed properties in general. This has been Armstrong's main focus since the late 1970s (e.g., *Universals* *and Scientific Realism*, 1978). There has been associated discussion of the idea of a *truthmaker* – an idea highlighted by C. B. Martin (e.g., "How It Is: Entities, Absences, and Voids," 1996), along with John Fox ("Truthmaker," 1987), John Bigelow (*The Reality of Numbers*, 1988), and Armstrong (*Truth and Truthmakers*, 2004). There has also been prominent discussion, more generally, of truth-at-all – realism or anti-realism about the world and our semantic relationship to it; see, e.g., Michael Devitt (*Realism and Truth*, 1984/1991), Huw Price (*Facts and the Function of Truth*, 1988), Brian Ellis (*Truth and Objectivity*, 1990), Bigelow and Robert Pargetter (*Science and Necessity*, 1990), and Barry Taylor (*Models, Truth, and Realism*, 2006).

Such work has arisen with encouragement from the distinctive tradition established by Australasian logicians. From New Zealand, A. N. Prior helped to initiate modern tense logic (e.g., *Time and Modality*, 1957). C. L. Hamblin (*Fallacies*, 1970) heightened contemporary interest in informal logic. New Zealanders M. J. Cresswell and G. E. Hughes wrote what was for many years the best-known textbook on modal logic (*An Introduction to Modal Logic*, 1972). Cresswell enriched our formal understanding of language (e.g., *Logics and Languages*, 1973), as did Richard Routley and Leonard Goddard (*The Logic of Significance and Context*, 1973). Several philosophers in the 1970s and onward – particularly Richard and Valerie Routley, Robert Meyer, Chris Mortensen (*Inconsistent Mathematics*, 1995), and Ross Brady (*Universal Logic*, 2006) – enlarged our conception of what *relevance* (or relevant) logics could encompass. Graham Priest has argued for dialetheism – there being true contradictions (*In Contradiction*, 1987). Other significant contributors are Greg Restall and Lloyd Humberstone.

Those various thoughts about mind, reality, and logic have complemented well the strength within Australasian philosophy of science: Brian Ellis (e.g., *Rational Belief Systems*, 1979), Peter Forrest (*Quantum Metaphysics*, 1988), Howard Sankey (e.g., *The Incommensurability Thesis*, 1994), Huw Price (*Time's Arrow and Archimedes' Point*, 1996), Paul Griffiths (e.g., *What Emotions Really Are*, 1997), Mark Colyvan (*The Indispensability of Mathematics*, 2001), Kim Sterelny (e.g., *Thought in a Hostile World*, 2003), and Peter Godfrey-Smith (*Darwinian Populations and Natural Selection*, 2009), among others. There has been related engagement with venerable questions about perception, memory, testimony, knowledge, and justification. There was much debate in the 1960s about perception, between Ellis, Armstrong (e.g., *Perception and the Physical World*, 1961), Max Deutscher, and J. L. Mackie. Later came Jackson's representationalism (*Perception*, 1977). On memory, Martin and Deutscher's causal account was influential ("Remembering," 1966), as was C. A. J. Coady's non-reductionism about testimony (*Testimony*, 1992). Armstrong developed one of the first reliabilist theories of knowledge (*Belief, Truth and Knowledge*, 1973). Fallibilism has been defended in different ways, such as by D. C. Stove (*The Rationality of Induction*, 1986) and the New Zealander Alan Musgrave (*Common Sense, Science and Scepticism*, 1993). Alan Hájek has advanced discussion of probability.

Australasian philosophy is not limited to metaphysics, logic, philosophy of mind, philosophy of science, and epistemology. Philosophy of religion is well represented, for instance by Martin (*Religious Belief*, 1959), John Passmore (*The Perfectibility of Man*, 1970), H. J. McCloskey (*God and Evil*, 1974), Robert Young (*Freedom, Responsibility, and God*, 1975), Mackie (*The Miracle of Theism*, 1982), Graham Oppy (e.g., *Ontological Arguments and Belief in God*, 1995), and Forrest (*God Without the Supernatural*, 1996). Feminist philosophy has been exemplified by Genevieve Lloyd (*The Man of Reason*, 1984/1993) and Moira Gatens (e.g., *Feminism and Philosophy*, 1991). There have also been substantial contributions to ethics, pure and applied. Smart defended utilitarianism (*Utilitarianism: For and Against*, 1973, with Bernard Williams). Peter Singer applied utilitarianism to non-human beings. His *Animal Liberation* (1975) has had worldly influence far beyond academia. Helga Kuhse joined Singer in applying more widely some of his utilitarian thinking (e.g., *Should the Baby Live?* 1985). More recently, the New Zealander Tim Mulgan (e.g., *The Demands of Consequentialism*, 2001) has extended the theoretical bases of such discussions. Applied ethics has had many Australian practitioners, such as Coady, John Kleinig, McCloskey, and Garrett Cullity (*The Moral Demands of Affluence*, 2004). Contemporary environmental philosophy, indeed, was seeded partly by Richard Routley (later, Richard Sylvan), Valerie Routley (later, Valerie Plumwood), and Passmore (*Man's Responsibility for Nature*, 1974).

The New Zealanders Rosalind Hursthouse (*On Virtue Ethics*, 1999) and Christine Swanton (*Virtue Ethics*, 2003) have expanded our historical and conceptual senses of what form a philosophical ethics can take. Australian contributors to moral and political philosophy have included McCloskey, Young (*Personal Autonomy*, 1986),

S. I. Benn (*A Theory of Freedom*, 1988), Michael Smith (*The Moral Problem*, 1994), Philip Pettit (e.g., *Republicanism*, 1997), and Jackson (*From Metaphysics to Ethics*, 1998). Skeptical questions about the reality of moral properties and the possibility of moral knowledge were posed provocatively in Mackie's *Ethics* (1977).

Running throughout some of these discussions has been a methodology that is often called the Canberra Plan. It is associated with ANU (Australian National University) and some influential philosophers, such as Jackson, Pettit, and Smith. Its inspiration was David Lewis's 1970s work on theoretical terms, which applied particularly the idea of a Ramsey sentence. Canberra planners seek to identify our most important *platitudes* about a given phenomenon; then to Ramsify those sentences, gaining in effect a theoretical description of the *role* that people in general believe is played by the phenomenon. The resulting conclusion is that the phenomenon is whatever best plays that role. For example, knowledge might be deemed to be whatever best fits the Ramsified role emerging from the seemingly platitudinous intuitions sparked so widely by Gettier cases.

Australasian philosophers have also contributed to the history of philosophy, especially of empiricism. Armstrong wrote on Berkeley and Locke; Martin joined him (e.g., "Substance Substantiated," 1980), as did Mackie (*Problems from Locke*, 1976). On Hume, there have been Passmore (*Hume's Intentions*, 1952), Stove (*Probability and Hume's Inductive Scepticism*, 1973), Annette Baier (*A Progress of Sentiments*, 1991), and Stephen Buckle (*Hume's Enlightenment Tract*, 2001). Stephen Gaukroger has written on Descartes (e.g., *Cartesian Logic*, 1989), Rae Langton on Kant (*Kantian Humility*, 1998), Paul Redding on Hegel (*Hegel's Hermeneutics*, 1996), Pettit on Hobbes (*Made With Words*, 2009), Peter Anstey on Boyle (*The Philosophy of Robert Boyle*, 2000) and on Locke (e.g., *John Locke and Natural Philosophy*, 2011), and Stewart Candlish on Bradley and Russell (*The Russell/Bradley Dispute and Its Significance for Twentieth-Century Philosophy*, 2007).

John Anderson's teaching at the University of Sydney (1927–58) sparked the work of several of the leading figures mentioned above. At the University of Melbourne, Douglas Gasking (during 1946–76) and A. C. Jackson (during 1948–66) were similarly influential. Enriching Australasian philosophy has been the *Australasian Journal of Philosophy*, founded in 1923 and still prominent. S.He.

Australian philosophy. See AUSTRALASIAN PHILOSOPHY.

Austrian philosophy, a philosophical term of art which, broadly construed, designates a philosophical tradition that includes philosophers who are either from Austria or influenced by Austrian culture. (An overview is provided by B. Smith, *Austrian Philosophy: The Legacy of Franz Brentano*, 1994.) So understood, it comprises philosophers ranging from Bolzano, Carnap, and Musil to Popper and Wittgenstein. Whether there is a distinctive Austrian tradition of philosophy is controversial. Less controversial is the view that there is a philosophical tradition that originated in Vienna and centered on Brentano, who taught in Vienna between 1874 and 1895. He taught Husserl, Meinong, Twardowski, Chr. von Ehrenfels, Carl Stumpf, and Anton Marty. These philosophers either defend and develop or reject and modify parts of Brentano's philosophy.

Brentano relied on four guiding assumptions: (1) The proper method of philosophy is the method of natural science. Like any natural science, philosophy attempts to systematize data. The difference is that, in general, philosophical data are not gathered in experiments. Brentano counts *attentive* introspection as an empirical method that yields data for the (descriptive) psychologist. (2) Psychology is the first science (*Psychology from an Empirical Standpoint*, 1874, Book I, 1 § 3). It is more valuable for human progress than any other science. (3) Genetic and descriptive psychology must be distinguished. Descriptive psychology is related to genetic psychology as anatomy is to physiology. *Descriptive psychology* (anatomy) decomposes the mind (body) into its basic elements (basic organs); *genetic psychology* (physiology) develops a theory of the functions of these elements (organs). (4) Descriptive psychology is concerned with the description and analysis of wholes. For example, a mental life is a unity which the descriptive psychologist decomposes into parts. These parts, mental phenomena, are, again, unities with parts. Brentano develops a theory of parts of wholes to describe the mind. Husserl, Stumpf, and others enrich and refine this theory. While Brentano's students differ in their views on core philosophical issues, they are unified in subscribing to Brentano's (1) to (4).

What are the core topics of the Brentano school? Brentano's main work, *Psychology from an Empirical Standpoint*, proposed that intentionality is the most distinctive mark of the mental: every mental phenomenon has an intentional (in-existing) object: a presentation is a presentation of something, a judgment an affirmation of something, and so on. A further mark of the mental is consciousness; i.e., one knows immediately that one thinks, feels, etc., if one does so. Mental phenomena come in pairs; the most fundamental are love–hate and acknowledgment (positive judgment)–rejection (negative judgment). The first opposition is the basis of Brentano's theory of value. Something is valuable (good) if it is correct to love it (see *The Foundation and Construction of Ethics*, 1889). These basic dichotomies are bones of contention in Austrian philosophy. For example, Reinach ("On the Theory of Negative Judgment," 1911) aimed to refute the view that judgment has a polar opposite, 'negative judgment'.

How do we know all this? We are immediately aware of our present mental activity. But while inner consciousness yields knowledge of mental acts, we cannot observe these mental acts *when we have them* (Brentano 1874, II, 2 § 9). Descriptive psychologists must therefore rely on memory and attention to acquire detailed knowledge of the mental.

Brentano's general epistemology is a variety of foundationalism: knowledge derived from evident judgments in evident steps. For Brentano, evidence guarantees truth. In "Toward an Epistemological Assessment of Memory" (1866) Meinong argued that memory beliefs have a different form of evidence that is not truth-guaranteeing: the *evidence of surmise* (*Vermutungsevidenz*).

Brentano made intentionality a core topic in philosophy. An important contribution to the understanding of intentionality in the Brentano school is Twardowski's *On the Content and Object of Presentations* (1894). Twardowski appealed to Bolzano, who argued in his *Wissenschaftslehre* (1837, 2d ed. Leipzig 1929) that there are ideas with no object (the idea of a golden mountain). For Brentanians this is false: an idea is just something that presents something. Twardowski argues (pro Brentano) that everything that is the topic of a mental act is an object, but (pro Bolzano) that not every object is real. Bolzano's logical realism that acknowledges propositions and other logical objects has had an important influence on several philosophers in the Brentano school, most importantly Husserl. Meinong further developed the thesis that every intentional act has an object by arguing that there are non-existent objects (see his "On the Theory of Objects," 1904). Russell's theory of definite descriptions is in part motivated by his criticism of Meinong's view in "On Denoting" (1905).

The fifth of Husserl's *Logical Investigations* (1900/1901, 2d ed. 1913) is a book-length discussion of Brentano's view of intentionality. In it Husserl changed tack and distinguished between the matter, quality, and object of a mental act. A mental phenomenon is intentional if, and only if, it has a matter. The matter of an act can be compared to a mode of presentation of an object. The matter-object distinction allows Husserl to say that mental phenomena such as imagining a golden mountain are intentional, although there is no such object as a golden mountain. Husserl's view is the starting point of what is now known as *phenomenology*.

The primacy of psychology informs the work of Brentanists in other areas of philosophy. For example, Marty (in *Untersuchungen zur Grundlegung der allgemeinen Grammatik und Sprachphilosophie*, 1908) developed a view of language on which its function is to express one's mental acts in order to change the mental life of others. Reinach investigated social acts like commanding, promising, etc. ("The A Priori Foundations of Civil Law," 1913). What is distinctive about these acts is their directedness on other thinkers and their mental acts.

The Brentano school forms a coherent and philosophically influential tradition. Husserl founded the phenomenological movement; Stumpf (see the two volumes of his *Tonpsychologie*, 1883 and 1890) made important contributions to the psychology of sound; Meinong and von Ehrenfels made the birth of Gestalt psychology possible; Twardowski was a major influence on Polish philosophy as the founder of the Lvov school of philosophy.

Vienna was the origin not only of the Brentano school, but also of the Vienna Circle. The Vienna Circle – well-known members are Rudolf Carnap, Hans Hahn, and Otto Neurath – revolved around Moritz Schlick in the 1920s and 1930s. In his *General Theory of Knowledge* (1918) Schlick criticized the epistemology of the Brentano school. This criticism is an integral part of the Vienna Circle's logical empiricism.

Ludwig Wittgenstein was in contact with the Vienna Circle and influenced its philosophical development (see *Wittgenstein and the Vienna Circle, Conversations Recorded by F. Waismann*, 1978). However, neither Wittgenstein's early nor his late philosophy seems to have distinctive Austrian roots.

autarkia, ancient Greek term meaning 'self-sufficiency'. *Autarkia* was widely regarded as a mark of the human good, happiness (*eudaimonia*). A life is self-sufficient when it is worthy of choice and lacks nothing. What makes a life self-sufficient – and thereby happy – was a matter of controversy. Stoics maintained that the mere possession of virtue would suffice; Aristotle and the Peripatetics insisted that virtue must be exercised and even, perhaps, accompanied by material goods. There was also a debate among later Greek thinkers over whether a self-sufficient life is solitary or whether only life in a community can be self-sufficient. **See also** ARISTOTLE, STOICISM. E.C.H.

authenticity. See EXISTENTIALISM, HEIDEGGER.

authority, the right or power to impose and enforce duties on others. Philosophical theories of authority are normally concerned with this kind of *practical* or *normative* authority. By contrast, *epistemic* or *theoretical* authority is the power over opinion possessed by those with superior knowledge or expertise in an area. In both cases, a pronouncement by an accepted authority provides us with reasons that are peremptory and content-independent. When a practical authority tells us how to act or an epistemic authority tells us what to believe, its status as an accepted authority gives us reason to simply comply, even when we cannot ourselves appreciate the reasons for its actions.

De facto practical authorities are those having the power (and claiming to have the right) to impose duties and enforce obedience on others. Many such authorities are also believed by (some or all of) those subject to this power to exercise it *legitimately*: to have the right to exercise it. In these cases, the practical authority has a kind of *psychological* authority over its subjects. Finally, some authorities – that may or may not also possess *de facto* authority – may in fact actually have the right to impose and enforce duties, giving them *de jure* practical authority over others.

Modern philosophical theories of practical authority developed against the background of the Pauline doctrine (from Romans 13) that all authority is instituted by God. That doctrine motivated a conception of specifically political authority – the divine right of kings – about which many moderns were deeply skeptical. As a result, attempts were made to distinguish the basis of God's authority from those of (what were taken to be) the other paradigms of authority: the authority of parents over their children, of conquerors over the conquered, and of kings (or governments) over their subjects. Modern theories of political authority were then defended that grounded it, e.g., in the consent of the governed (as in Locke) or in its necessity for doing justice (as in Kant).

Contemporary theories of practical authority have continued to focus primarily on the nature and justification of legal and political authority, defending additional grounds for such authority in, e.g., considerations of fairness or associative responsibilities. But the perceived failure of these (and other) accounts has also given rise to a significant skeptical tradition that either denies the very possibility of *de jure* political authority or denies that most (or any) *de facto* political authorities possess their authority legitimately. avatar (from Sanskrit *avatāra*), in Hindu thought, any of the repeated "descents" of the

Supreme Being into the physical world as an animal, human being, or combination thereof, to destroy evil and restore order. Predominantly identified as the actions of the god Vishnu, these entrances into the world indicate that Vishnu as lord will adjust the cycle of karma. Its earliest reference is in the Bhagavad Gita (150 B.C.), where Krishna says that whenever dharma languishes he incarnates in age after age to destroy evildoers and promote the good. Later lists of avatars of Vishnu cite ten, twenty, or more, with Krishna and the Buddha as famous examples. The inclusion of prominent local deities in the list brought them under the influence of Vishnu devotees, and today even Jesus and Muhammad may be included. Modern philosophers such as Radhakrishnan (1888–1975) redefine the concept non-theistically, identifying an avatar as a human being who has attained enlightenment. R.N.Mi.

Avempace. See IBN BĀJJA.

Avenarius, Richard (1843–96), German philosopher. He was born in Paris and educated at the University of Leipzig. He became a professor at Leipzig and succeeded Windelband at the University of Zürich in 1877. For a time he was editor of the *Zeitschrift für wissenschaftliche Philo-sophie*. His earliest work was *Über die beiden ersten Phasen des Spinozischen Pantheismus* (1868). His major work, *Kritik der reinen Erfahrung* ("Critique of Pure Experience," 2 vols., 1888–90), was followed by his last study, *Der menschliche Weltbe-griffe* (1891).

In his post-Kantian *Kritik* Avenarius presented a radical positivism that sought to base philosophy on scientific principles. This "empiriocriticism" emphasized "pure experience" and descriptive and general definitions of experience. Metaphysical claims to transcend experience were rejected as mere creations of the mind. Like Hume, Avenarius denied the ontological validity of substance and causality. Seeking a scientific empiricism, he endeavored to delineate a descriptive determination of the form and content of pure experience. He thought that the subject-object dichotomy, the separation of inner and outer experiences, falsified reality. If we could avoid "introjecting" feeling, thought, and will into experience (and thereby splitting it into subject and object), we could attain the original "natural" view of the world.

Although Avenarius, in his *Critique of Pure Experience*, thought that changes in brain states parallel states of consciousness, he did not reduce sensations or states of consciousness to physiological changes in the brain. Because his theory of pure experience undermined dogmatic materialism, Lenin attacked his philosophy in *Materialism and Empirio-Criticism* (1952). His epistemology influenced Mach, and his emphasis upon pure experience had considerable influence on James.

Averroes, in Arabic, Ibn Rushd (1126–98), Islamic philosopher, jurist, and physician; scion of a long line of *qādīs* (religious judges). He was born at Córdova and educated in Islamic law. Introduced to the Almohad ruler by Ibn Tufayl, author of the philosophical allegory *Hayy Ibn Yaqzan*, he feigned ignorance of philosophy, only to learn that the leader of the dynasty so feared for its orthodoxy was thoroughly at home with philosophical issues. He was given a robe of honor and a mount and later invited to write his famous commentaries on Aristotle and made *qādī* of Seville, finally succeeding Ibn Tufayl as royal physician and becoming chief *qādī* of Córdova. He was persecuted when the sultan's successor needed orthodox support in his war with Christian Spain, but died in the calm of Marrakesh, the edicts against him rescinded.

His works, most often preserved in Hebrew or Latin translations ('Averroes' reflects efforts to Latinize 'Ibn Rushd'), include medical and astronomical writings; short, middle, and long commentaries on Aristotle ("his was the ultimate human mind"); a commentary on Plato's *Republic;* and spirited juridical and conceptual defenses of philosophy: *The Decisive Treatise* and *Incoherence of the Incoherence*. The former argues that philosophy, although restricted to the adept, is *mandated* by the Koranic (59:2) injunction to reflect on God's design. The latter answers al-Ghazālī's *Incoherence of the Philosophers*, defending naturalism and its presumed corollary, the world's eternity, but often cutting adrift the more Platonizing and original doctrines of Avicenna, al-Ghazālī's chief stalking horse. Thus Averroes rejects Avicenna's idea that the world itself is contingent if it is necessitated by its causes, arguing that removing the necessity that is the hallmark of God's wisdom would leave us no way of inferring a wise Author of nature. Ultimately Averroes rejects emanation and seeks to return natural theology to the physics of matter and motion, discrediting Avicenna's metaphysical approach and locating God's act in the ordering of eternal matter. On bodily resurrection, individual providence, and miracles, he takes refuge in authority, fudge, and bluff; and even his defense of causal necessity smacks of a dogmatism expressive of the awkwardness of his position and the stiffening of Peripatetic thought. Yet he retains the idea that the intellect is immortal, indeed impersonal: since only matter differentiates individuals, all minds are ultimately one; they reach fulfillment and beatitude by making contact (*ittisāl;* cf. Plotinus's *aphe*) with the Active Intellect.

Many Jewish philosophers like Narboni and Albalag followed Averroes' arguments explicitly, reinterpreting Maimonides accordingly. But Averroes' efforts to accommodate rhetorical and dialectical along with philosophical discourse led to the branding of his Christian followers as exponents of a "double truth," although no text advances such a doctrine. Siger of Brabant, Boethius of Dacia, and Bernier of Nivelles were condemned for Averroistic heresies at Paris in the 1270s. But from the thirteenth to mid-seventeenth centuries Latin scholars regularly read Aristotle with Averroes' commentaries. His philosophic respondents include Ibn Taymiyya (d.1327), Gersonides, Albertus Magnus, and Aquinas. Spinoza's dogged eternalism links him vividly to Averroes.

Avicebron. See IBN GABIROL.

Avicenna, in Arabic, Ibn Sinā (980–1037), Islamic philosopher and physician. Born near Bukhara, where his father served as a provincial governor, Avicenna came to manhood as the Persian Samanid dynasty was crumbling and spent much of his life fleeing from court to court to avoid the clutches of the rapacious conqueror Mahmūd of Ghaznā. His autobiography describes him as an intuitive student of philosophy and other Greek sciences who could not see the point of Aristotle's *Metaphysics*, until he read a tiny essay by al-Fārābī (870–950), who showed him what it means to seek the nature of being as such.

It was in metaphysics that Avicenna made his greatest contributions to philosophy, brilliantly synthesizing the rival approaches of the Aristotelian-Neoplatonic tradition with the creationist monotheism of Islamic dialectical theology (*kalām*). Where Aristotle sought and found being in its fullest sense in what was changeless in its nature (above all, in the species of things, the heavenly bodies, the cosmos as a whole), *kalām* understood being as the immediately given, allowing no inference beyond a single contingent datum to any necessary properties, correlatives, continuators, or successors. The result was a stringent atomist occasionalism resting ultimately on an early version of logical atomism. Avicenna preserved an Aristotelian naturalism alongside the scriptural idea of the contingency of the world by arguing that any finite being is contingent in itself but necessary in relation to its causes. He adapted al-Fārābī's Neoplatonic emanationism to this schematization and naturalized in philosophy his own distinctive version of the *kalām* argument from contingency: any being must be either necessary or contingent, but if contingent, it requires a cause; since no infinite causal regress is possible, there must be a Necessary Being, which is therefore simple, the ultimate cause of all other things.

Avicenna found refuge at the court of one 'Alā al-Dawla, who bravely resisted the military pressures of Mahmūd against his lands around Isfahan and made the philosopher and savant his vizier. Here Avicenna completed his famous philosophic work the *Shifā'* (known in Latin as the *Sufficientia*) and his *Qānūn fi Tibb*, the Galenic *Canon*, which remained in use as a medical textbook until finally brought down by the weight of criticisms during the Renaissance. Avicenna's philosophy was the central target of the polemical critique of the Muslim theologian al-Ghazālī (1058–1111) in his *Incoherence of the Philosophers*, mainly on the grounds that the philosopher's retention of the Aristotelian doctrine of the eternity of the world was inconsistent with his claim that God was the author of the world. Avicenna's related affirmations of the necessity of causation and universality of God's knowledge, al-Ghazālī argued, made miracles impossible and divine governance too impersonal to deserve the name. Yet Avicenna's philosophic works (numbering over a hundred in their Arabic and sometimes Persian originals) continued to exercise a major influence on Muslim and Jewish philosophers and (through Latin translations) on philosophers in the West.

avidya (Sanskrit, 'ignorance', 'lack of wisdom'), a key concept in India's philosophical systems, which attempt to explain the reasons for karmic bondage leading to suffering and release from such bondage through spiritual liberation. The general idea is that karmic fetters arise because of *avidya*, which is ignorance of the true nature of reality. When wisdom dispels *avidya*, the individual is freed from bondage. There was intense speculation in Indian philosophy regarding the nature and the metaphysical status of *avidya*. If *avidya* causes bondage that traps the individual in the transmigratory cycle of life and death (*samsāra*), then where does *avidya* reside and how does it come into being? D.K.C.

awareness, consciousness, a central feature of our lives. You experience goings-on in the world, and, turning inward ("introspecting"), you experience your experiencing. Objects of awareness can be external or internal. Pressing your finger on the edge of a table, you can be aware of the table's edge and aware of the feeling of pressure (though perhaps not simultaneously). Philosophers from Locke to Thomas Nagel have insisted that our experiences have distinctive qualities: there is "something it is like" to have them. It would seem important, then, to distinguish qualities of objects of which you are aware from qualities of your awareness. Suppose you are aware of a round, red tomato. The tomato, but not your awareness, is round and red. What then are the qualities of your awareness? Here we encounter a deep puzzle that divides theorists into intransigent camps.

Some materialists, like Dennett, insist that awareness lacks qualities (or lacks qualities distinct from its objects: the qualities we attribute to experiences are really those of experienced objects). This opens the way to a dismissal of phenomenal qualities (qualia), qualities that seem to have no place in the material world. Others (Nagel, Ned Block) regard such qualities as patently genuine, preferring to dismiss any theory unable to accommodate them. Convinced that the qualities of awareness are ineliminable and irreducible to respectable material properties, some philosophers, following Jackson, contend they are "epiphenomenal": real but causally inefficacious. Still others, including Searle, point to what they regard as a fundamental distinction between the "intrinsically subjective" character of awareness and the "objective," "public" character of material objects, but deny that this yields epiphenomenalism.

See also PHENOMENOLOGY, PHILOSOPHY OF MIND, QUALIA. J.F.H.

axiology. See VALUE THEORY.

axiom. See AXIOMATIC METHOD.

axiomatic method, originally, a method for reorganizing the accepted propositions and concepts of an existent science in order to increase certainty in the propositions and clarity in the concepts. Application of this method was thought to require the identification of (1) the "universe of discourse" (domain, genus) of entities constituting the primary subject matter of the science, (2) the "primitive concepts" that can be grasped immediately without the use of definition, (3) the "primitive propositions" (or "axioms"), whose truth is knowable immediately, without the use of deduction, (4) an immediately acceptable "primitive definition" in terms of primitive concepts for each non-primitive concept, and (5) a deduction (constructed by chaining immediate, logically cogent inferences ultimately from primitive propositions and definitions) for each non-primitive accepted proposition. Prominent proponents of more or less modernized versions of the axiomatic method, e.g. Pascal, Nicod (1893–1924), and Tarski, emphasizing the critical and regulatory function of the axiomatic method, explicitly open the possibility that axiomatization of an existent, preaxiomatic science may lead to rejection or modification of propositions, concepts, and argumentations that had previously been accepted.

In many cases attempts to realize the ideal of an axiomatic science have resulted in discovery of "smuggled premises" and other previously unnoted presuppositions, leading in turn to recognition of the need for new axioms. Modern axiomatizations of geometry are much richer in detail than those produced in ancient Greece. The earliest extant axiomatic text is based on an axiomatization of geometry due to Euclid (fl. 300 B.C.), which itself was based on earlier, no-longer-extant texts. Archimedes (287–212 B.C.) was one of the earliest of a succession of post-Euclidean geometers, including Hilbert, Oswald Veblen (1880–1960), and Tarski, to propose modifications of axiomatizations of classical geometry. The traditional axiomatic method, often called the geometric method, made several presuppositions no longer widely accepted. The advent of non-Euclidean geometry was particularly important in this connection.

For some workers, the goal of reorganizing an existent science was joined to or replaced by a new goal: characterizing or giving implicit definition to the structure of the subject matter of the science. Moreover, subsequent innovations in logic and foundations of mathematics, especially development of syntactically precise formalized languages and effective systems of formal deductions, have substantially increased the degree of rigor attainable. In particular, critical axiomatic exposition of a body of scientific knowledge is now not thought to be fully adequate, however successful it may be in realizing the goals of the original axiomatic method, so long as it does not present the underlying logic (including language, semantics, and deduction system). For these and other reasons 'axiomatic method' has undergone many "redefinitions," some having only the most tenuous connection with the original meaning.

See also CATEGORICITY, DEDUCTION, FORMALIZATION. J.Cor.

axiomatic system. See AXIOMATIC METHOD, DEDUCTION.

axiom of abstraction. See AXIOM OF COMPREHENSION.

axiom of choice. See LÖWENHEIM-SKOLEM THEOREM, SET THEORY.

axiom of comprehension, also called axiom of abstraction, the axiom that for every property, there is a corresponding set of things having that property; i.e., $(\phi)(\exists A)(x)\ (x \in A \equiv \phi x)$, where ϕ is a property and A is a set. The axiom was used in Frege's formulation of set theory and is the axiom that yields Russell's paradox, discovered in 1901. If ϕx is instantiated as $x \notin x$, then the result that $A \in A \equiv A \notin A$ is easily obtained, which yields, in classical logic, the explicit contradiction $A \in A \equiv A \notin A$. The paradox can be avoided by modifying the comprehension axiom and using instead the separation axiom, $(\phi)(\exists A)(x)\ (x \in A \equiv (\phi x \,\&\, x \in B))$. This yields only the result that $A \in A \equiv (A \notin A \,\&\, A \in B)$, which is not a contradiction. The paradox can also be avoided by retaining the comprehension axiom but restricting the symbolic language, so that '$x \in x$' is not a meaningful formula. Russell's type theory, presented in *Principia Mathematica*, uses this approach. **See also** FREGE, RUSSELL, SET THEORY, TYPE THEORY. V.K.

axiom of consistency, an axiom stating that a given set of sentences is consistent. Let L be a formal language, D a deductive system for L, S any set of sentences of L, and C the statement 'S is consistent' (i.e., 'No contradiction is derivable from S via D'). For certain sets S (e.g., the theorems of D) it is interesting to ask: Can C be expressed in L? If so, can C be proved in D? If C can be expressed in L but not proved in D, can C be added (consistently) to D as a new axiom? Example (from Gödel): Let L and D be adequate for elementary number theory, and S be the axioms of D; then C can be expressed in L but not proved in D, but can be added as a new axiom to form a stronger system D'. Sometimes we can express in L an axiom of consistency in the semantic sense (i.e., 'There is a universe in which all the sentences in S are true'). Trivial example: suppose the only non-logical axiom in D is 'For any two sets B and B', there exists the union of B and B''. Then C might be 'There is a set U such that, for any sets B and B' in U, there exists in U the union of B and B''. **See also** CONSISTENCY, PROOF THEORY. D.H.

Ayer, A(lfred) J(ules) (1910–89), British philosopher, one of the most important of the British logical positivists. He continued to occupy a dominant place in analytic philosophy even as he gradually modified his adherence to central tenets of the view. He was educated at Eton and Oxford, and, after a brief period at the University of Vienna, became a lecturer in philosophy at Christ Church College, Oxford in 1933. After the war he returned to Oxford as fellow and dean of Wadham College. He was Grote Professor of the Philosophy of Mind and Logic at the University of London (1946–59), Wykeham Professor of Logic in the University of Oxford and a fellow of New College (1959–78), and a fellow of Wolfson College, Oxford (1978–83). Ayer was knighted in 1973 and was a Chevalier de la Légion d'Honneur.

His early work clearly and forcefully developed the implications of the positivists' doctrines that all cognitive statements are either analytic and a priori, or synthetic, contingent, and a posteriori, and that empirically meaningful statements must be verifiable (must admit of confirmation or disconfirmation). In doing so he defended reductionist analyses of the self, the external world, and other minds. Value statements that fail the empiricist's criterion of meaning but defy naturalistic analysis were denied truth-value and assigned *emotive meaning*. Throughout his writings he maintained a foundationalist perspective in epistemology in which sense-data (later more neutrally described) occupied not only a privileged epistemic position but constituted the subject matter of the most basic statements to be used in reductive analyses. Although in later works he significantly modified many of his early views and abandoned much of their strict reductionism, he remained faithful to an empiricist's version of foundationalism and the basic idea behind the verifiability criterion of meaning. His books include *Language, Truth and Logic; The Foundations of Empirical Knowledge; The Problems of Knowledge; Philosophical Essays; The Concept of a Person; The Origins of Pragmatism; Metaphysics and Common Sense; Russell and Moore: The Analytical Heritage; The Central Questions of Philosophy; Probability and Evidence; Philosophy in the Twentieth Century; Bertrand Russell; Hume; Freedom and Morality; Ludwig Wittgenstein;* and *Voltaire*.

Babbage, Charles (1792–1871), English applied mathematician, inventor, and expert on machinery and manufacturing. His chief interest was in developing mechanical "engines" to compute tables of functions. Until the invention of the electronic computer, printed tables of functions were important aids to calculation. Babbage invented the *difference engine*, a machine that consisted of a series of accumulators each of which, in turn, transmitted its contents to its successor, which added them to its own contents. He built only a model, but George and Edvard Scheutz built difference engines that were actually used. Though tables of squares and cubes could be calculated by a difference engine, the more commonly used tables of logarithms and of trigonometric functions could not. To calculate these and other useful functions, Babbage conceived of the *analytical engine*, a machine for numerical analysis.

The analytical engine was to have a store (memory) and a mill (arithmetic unit). The store was to hold decimal numbers on toothed wheels, and to transmit them to the mill and back by means of wheels and toothed bars. The mill was to carry out the arithmetic operations of addition, subtraction, multiplication, and division mechanically, greatly extending the technology of small calculators. The operations of the mill were to be governed by pegged drums, derived from the music box.

A desired sequence of operations would be punched on cards, which would be strung together like the cards of a Jacquard loom and read by the machine. The control mechanisms could branch and execute a different sequence of cards when a designated quantity changed sign. Numbers would be entered from punched cards and the answers punched on cards. The answers might also be imprinted on metal sheets from which the calculated tables would be printed, thus avoiding the errors of proofreading.

Although Babbage formulated various partial plans for the analytical engine and built a few pieces of it, the machine was never realized. Given the limitations of mechanical computing technology, building an analytical engine would probably not have been an economical way to produce numerical tables. The modern electronic computer was invented and developed completely independently of Babbage's pioneering work. Yet because of it, Babbage's work has been publicized and he has become famous.

Bachelard, Gaston (1884–1962), French philosopher of science and literary analyst. His philosophy of science (developed, e.g., in *The New Scientific Spirit*, 1934, and *Rational Materialism*, 1953) began from reflections on the relativistic and quantum revolutions in twentieth-century physics. Bachelard viewed science as developing through a series of discontinuous changes (epistemological breaks). Such breaks overcome *epistemological obstacles:* methodological and conceptual features of commonsense or outdated science that block the path of inquiry. Bachelard's emphasis on the discontinuity of scientific change strikingly anticipated Thomas Kuhn's focus, many years later, on revolutionary paradigm change. However, unlike Kuhn, Bachelard held to a strong notion of scientific progress across revolutionary discontinuities. Although each scientific framework rejects its predecessors as fundamentally erroneous, earlier frameworks may embody permanent achievements that will be preserved as special cases within subsequent frameworks. (Newton's laws of motion, e.g., are special limit-cases of relativity theory.)

Bachelard based his philosophy of science on a "non-Cartesian epistemology" that rejects Descartes's claim that knowledge must be founded on incorrigible intuitions of first truths. All knowledge claims are subject to revision in the light of further evidence. Similarly, he rejected a naive realism that defines reality in terms of givens of ordinary sense experience and ignores the ontological constructions of scientific concepts and instrumentation. He maintained, however, that denying this sort of realism did not entail accepting idealism, which makes only the mental ultimately real. Instead he argued for an "applied rationalism," which recognizes the active role of reason in constituting objects of knowledge while admitting that any constituting act of reason must be directed toward an antecedently given object.

Although Bachelard denied the objective reality of the perceptual and imaginative worlds, he emphasized their subjective and poetic significance. Complementing his writings on science are a series of books on imagination and poetic imagery (e.g., *The Psychoanalysis of Fire*, 1938; *The Poetics of Space*, 1957) which subtly unpack the meaning of archetypal (in Jung's sense) images. He put forward a "law of the four elements," according to which all images can be related to the earth, air, fire, and water posited by Empedocles as the fundamental forms of matter.

Together with Georges Canguilhem, his successor at the Sorbonne, Bachelard had an immense impact on several generations of French students of philosophy. He and Canguilhem offered an important alternative to the more fashionable and widely known phenomenology and existentialism and were major influences on (among others) Althusser and Foucault.

backward causation. See CAUSATION.

Bacon, Francis (1561–1626), English philosopher, essayist, and scientific methodologist. In politics Bacon rose to the position of lord chancellor. In 1621 he retired to private life after conviction for taking bribes in his official capacity as judge.

Bacon championed the new empiricism resulting from the achievements of early modern science. He opposed alleged knowledge based on appeals to authority, and on the barrenness of Scholasticism. He thought that what was needed was a new attitude and methodology based strictly on scientific practices. The goal of acquiring knowledge is the good of mankind: knowledge is power. The social order that should result from applied science is portrayed in his *New Atlantis* (1627). The method of induction to be employed is worked out in detail in his *Novum Organum* (1620). This new logic is to replace that of Aristotle's syllogism, as well as induction by simple enumeration of instances. Neither of these older logics can produce knowledge of actual natural laws. Bacon thought that we must intervene in nature, manipulating it by means of experimental control leading to the invention of new technology.

There are well-known hindrances to acquisition of knowledge of causal laws. Such hindrances (false opinions, prejudices), which "anticipate" nature rather than explain it, Bacon calls idols (*idola*). *Idols of the tribe* (*idola tribus*) are natural mental tendencies, among which are the idle search for purposes in nature, and the impulse to read our own desires and needs into nature. *Idols of the cave* (*idola specus*) are predispositions of particular individuals. The individual is inclined to form opinions based on idiosyncrasies of education, social intercourse, reading, and favored authorities. *Idols of the marketplace* (*idola fori*) Bacon regards as the most potentially dangerous of all dispositions, because they arise from common uses of language that often result in verbal disputes. Many words, though thought to be meaningful, stand for nonexistent things; others, although they name actual things, are poorly defined or used in confused ways. *Idols of the theater* (*idola theatri*) depend upon the influence of received theories. The only authority possessed by such theories is that they are ingenious verbal constructions. The aim of acquiring genuine knowledge does not depend on superior skill in the use of words, but rather on the discovery of natural laws. Once the idols are eliminated, the mind is free to seek knowledge of natural laws based on experimentation. Bacon held that nothing exists in nature except bodies (material objects) acting in conformity with fixed laws. These laws are "forms." For example, Bacon thought that the form or cause of heat is the motion of the tiny particles making up a body. This form is that on which the existence of heat depends. What induction seeks to show is that certain laws are perfectly general, universal in application. In every case of heat, there is a measurable change in the motion of the particles constituting the moving body.

Bacon thought that scientific induction proceeds as follows. First, we look for those cases where, given certain changes, certain others invariably follow. In his example, if certain changes in the form (motion of particles) take place, heat always follows. We seek to find all of the "positive instances" of the form that give rise to the effect of that form. Next, we investigate the "negative instances," cases where, in the absence of the form, the qualitative change does not take place. In the operation of these methods it is important to try to produce experimentally "prerogative instances," particularly striking or typical examples of the phenomenon under investigation. Finally, in cases where the object under study is present to some greater or lesser degree, we must be able to take into account why these changes occur. In the example, quantitative changes in degrees of heat will be correlated to quantitative changes in the speed of the motion of the particles. This method implies that in many cases we can invent instruments to measure changes in degree. Such inventions are of course the hoped-for outcome of scientific inquiry, because their possession improves the lot of human beings.

Bacon's strikingly modern (but not entirely novel) empiricist methodology influenced nineteenth-century figures (e.g., Sir John Herschel and J. S. Mill) who generalized his results and used them as the basis for displaying new insights into scientific methodology.

R.E.B.

Bacon, Roger (c.1214–c.1293), English philosopher who earned the honorific title of *Doctor Mirabilis*. He was one of the first medievals in the Latin West to lecture and comment on newly recovered work by Aristotle in natural philosophy, physics, and metaphysics. Born in Somerset and educated at both Oxford University and the University of Paris, he became by 1273 a master of arts at Paris, where he taught for about ten years. In 1247 he resigned his teaching post to devote his energies to investigating and promoting topics he considered neglected but important insofar as they would lead to knowledge of God. The English "experimentalist" Grosseteste, the Frenchman Peter of Maricourt, who did pioneering work on magnetism, and the author of the pseudo-Aristotelian *Secretum secretorum* influenced Roger's new perspective. By 1257, however, partly from fatigue, Roger had put this work aside and entered the Franciscan order in England. To his dismay, he did not receive within the order the respect and freedom to write and teach he had expected.

During the early 1260s Roger's views about reforming the university curriculum reached Cardinal Guy le Gos de Foulques, who, upon becoming Pope Clement IV in 1265, demanded to see Roger's writings. In response, Roger produced the *Opus maius* (1267) – an encyclopedic work that argues, among other things, that (1) the study of Hebrew and Greek is indispensable for understanding the Bible, (2) the study of mathematics (encompassing geometry, astronomy, and astrology) is, with experimentation, the key to all the sciences and instrumental in theology, and (3) philosophy can serve theology by helping in the conversion of non-believers. Roger believed that although the Bible is the basis for human knowledge, we can use reason in the service of knowledge. It is not that rational argument can, on his view, provide full-blown proof of anything, but rather that with the aid of reason one can formulate hypotheses about nature that can be confirmed by experience. According to Roger, knowledge arrived at in this way will lead to knowledge of nature's creator. All philosophical, scientific, and linguistic endeavors are valuable ultimately for the service they can render to theology. Roger summarizes and develops his views on these matters in the *Opus minus* and the *Opus tertium*, produced within a year of the *Opus maius*.

Roger was altogether serious in advocating curricular change. He took every opportunity to rail against many of his celebrated contemporaries (e.g., Alexander of Hales, Bonaventure, Albertus Magnus, and Aquinas) for not being properly trained in philosophy and for contributing to the demise of theology by lecturing on Peter Lombard's *Sentences* instead of the Bible. He also wrote both Greek and Hebrew grammars, did important work in optics, and argued for calendar reform on the basis of his (admittedly derivative) astronomical research. One should not, however, think that Roger was a good mathematician or natural scientist. He apparently never produced a single theorem or proof in mathematics, he was not always a good judge of astronomical competence (he preferred al-Bitrūjī to Ptolemy), and he held alchemy in high regard, believing that base metals could be turned into silver and gold. Some have gone so far as to claim that Roger's renown in the history of science is vastly overrated, based in part on his being confusedly linked with the fourteenth-century Oxford Calculators, who do deserve credit for paving the way for certain developments in seventeenth-century science.

Roger's devotion to curricular reform eventually led to his imprisonment by Jerome of Ascoli (the future Pope Nicholas IV), probably between 1277 and 1279. Roger's teachings were said to have contained "suspect novelties." Judging from the date of his imprisonment, these novelties may have been any number of propositions condemned by the bishop of Paris, Étienne Tempier, in 1277. But his imprisonment may also have had something to do with the anger he undoubtedly provoked by constantly abusing the members of his order regarding their approach to education, or with his controversial Joachimite views about the apocalypse and the imminent coming of the Antichrist.

Given Roger's interest in educational reform and his knack for systematization, it is not unlikely that he was abreast of and had something to say about most of the central philosophical issues of the day. If so, his writings could be an important source of information about thirteenth-century Scholastic philosophy generally. In this connection, recent investigations have revealed, e.g., that he may well have played an important role in the development of logic and philosophy of language during the thirteenth and early fourteenth centuries. In the course of challenging the views of certain people (some of whom have been tentatively identified as Richard of Cornwall, Lambert of Auxerre, Siger of Brabant, Henry of Ghent, Boethius of Dacia, William Sherwood, and the Magister Abstractionum) on the nature of signs and how words function as signs, Roger develops and defends views that appear to be original. The pertinent texts include the *Sumule dialectices* (c.1250), the *De signis* (in Part III of the *Opus maius*), and the *Compendium studii theologiae* (1292). For example, in connection with the question whether Jesus could be called a man during the three-day entombment (and, thus, in connection with the related question whether man can be said to be animal when no man exists, and with the sophism 'This is a dead man, therefore this is a man'), Roger was not content to distinguish words from all other signs as had been the tradition. He distinguished between signs originating from nature and from the soul, and between natural signification and conventional (*ad placitum*) signification, which results expressly or tacitly from the imposition of meaning by one or more individuals. He maintained that words signify existing and nonexisting entities only equivocally, because words conventionally signify only presently existing things. On this view, therefore, 'man' is not used univocally when applied to an existing man and to a dead man.

Baden School. See NEO-KANTIANISM.

bad faith, (1) dishonest and blameworthy instances of self-deception; (2) inauthentic and self-deceptive refusal to admit to ourselves and others our full freedom, thereby avoiding anxiety in making decisions and evading responsibility for actions and attitudes (Sartre, *Being and Nothingness*, 1943); or (3) hypocrisy or dishonesty in speech and conduct, as in making a promise without intending to keep it. One self-deceiving strategy identified by Sartre is to embrace other people's views in order to avoid having to form one's own; another is to disregard options so that one's life appears predetermined to move in a fixed direction. Occasionally Sartre used a narrower, fourth sense: self-deceptive beliefs held on the basis of insincere and unreasonable interpretations of evidence, as contrasted with the dishonesty of "sincerely" acknowledging one truth (I am disposed to be a thief) in order to deny a deeper truth (I am free to change). **See also** FALSE CONSCIOUSNESS, SARTRE, VITALLIE. M.W.M.

Badiou, Alain (b.1937), the leading French philosopher since the death of Derrida. Like Deleuze, Badiou was not daunted by proclamations of the "death of philosophy" and, in his magnum opus, *Being and Event* (1988), developed an impressive systematic metaphysics in the traditional grand manner. Moreover, contrary to postmodern trends, he endorses objective truth and offers philosophical accounts of the subject and of ethics. He maintains that the perennial question about the nature of being *qua* being is entirely answered by the mathematical theory of sets, which he uses to construct a formal ontology. But he complements this general ontology with a treatment of the concrete events that inject revolutionary novelties into the four historical domains of science, politics, art, and love. These are the realm of the subject and of ethics.

In his student days, Badiou belonged – along with Jacques Rancière (b.1940) and Étienne Balibar (b.1942) – to a circle strongly influenced by the Marxism of Louis Althusser. He has been a political activist since that time and, unlike many, has maintained a basic allegiance to the radical views of the May 1968 protests. He has also had success as a novelist and as a playwright.

bad-making. See GOOD-MAKING CHARACTERISTIC.

Bain, Alexander (1818–1903), British philosopher and reformer, biographer of James Mill (1882) and J. S. Mill (1882) and founder of the first psychological journal, *Mind* (1876). In the development of psychology, Bain represents in England (alongside Continental thinkers such as Taine and Lotze) the final step toward the founding of psychology as a science. His significance stems from his wish to "unite psychology and physiology," fulfilled in *The Senses and the Intellect* (1855) and *The Emotions and the Will* (1859), abridged in one volume, *Mental and Moral Science* (1868). Neither Bain's psychology nor his physiology were particularly original. His psychology came from English empiricism and associationism, his physiology from Johannes Muller's (1801–58) *Elements of Physiology* (1842). Muller was an early advocate of the reflex, or sensorimotor, conception of the nervous system, holding that neurons conduct sensory information to the brain or motor commands from the brain, the brain connecting sensation with appropriate motor response. Like Hartley before him, Bain grounded the laws of mental association in the laws of neural connection. In opposition to faculty psychology, Bain rejected the existence of mental powers located in different parts of the brain (*On the Study of Character*, 1861). By combining associationism with modern physiology, he virtually completed the movement of philosophical psychology toward science. In philosophy, his most important concept was his analysis of belief as "a preparation to act." By thus entwining conception and action, he laid the foundation for pragmatism, and for the focus on adaptive behavior central to modern psychology. **See also** ASSOCIATIONISM. T.H.L.

Baker, Lynne Rudder (b.1944), American philosopher who defends a *practical realism:* the practice of everyday life is ontologically real; it is *not* second-class, to be replaced by science in the long run. The world of persons, intentional states, natural language, social institutions, and artifacts is ontologically irreducible and as real as the subatomic world (*The Metaphysics of Everyday Life: An Essay in Practical Realism*, 2007).

Baker is a severe critic of reductionist and eliminativist approaches to mental states (*Saving Belief: A Critique of Physicalism*, 1987). Mental states should be conceived as relational states of whole persons. Whether a person *S* has a particular belief *B* is determined by what *S* does, says, and thinks, and what *S would* do, say, and think in various circumstances (*Explaining Attitudes: A Practical Approach to the Mind*, 1995).

Baker conceives the relation between a person and her body in terms of the metaphysical relation of *constitution*. Persons are constituted by, but not identical to, or separate from their bodies (*Persons and Bodies: A Constitution View*, 2000). A person is essentially a being with a first-person perspective. A robust first-person perspective requires a concept of self. Having such a concept involves, in Baker's externalist view, language and social relations. A first-person perspective is a condition for agency, for assessing one's beliefs and desires, and for moral responsibility (*Naturalism and the First-Person Perspective*, 2013). A.Mei.

Bakhtin, Mikhail Mikhailovich (1895–1975), Russian philosopher and cultural theorist whose influence is pervasive in a wide range of academic disciplines – from literary hermeneutics to the epistemology of the human sciences, cultural theory, and feminism. He may legitimately be called a philosophical anthropologist in the venerable Continental tradition. Because of his seminal work on Rabelais and Dostoevsky's poetics, his influence has been greatest in literary hermeneutics.

Without question, dialogism, or the construal of dialogue, is the hallmark of Bakhtin's thought. Dialogue marks the existential condition of humanity in which the self and the other are asymmetrical but double-binding. In his words, to exist means to communicate dialogically, and when the dialogue ends, everything else ends. Unlike Hegelian and Marxian dialectics but like the Chinese correlative logic of yin and yang, Bakhtin's dialogism is infinitely polyphonic, open-ended, and indeterminate, i.e. "unfinalizable" – to use his term. Dialogue means that there are neither first nor last words. The past and the future are interlocked and revolve around the axis of the present.

Bakhtin's dialogism is paradigmatic in a threefold sense. First, dialogue is never abstract but embodied. The lived body is the material condition of social existence as ongoing dialogue. Not only does the word become enfleshed, but dialogue is also the incorporation of the self and the other. Appropriately, therefore, Bakhtin's body politics may be called a Slavic version of Tantrism. Second, the Rabelaisian carnivalesque that Bakhtin's dialogism incorporates points to the "jesterly" politics of resistance and protest against the "priestly" establishment of officialdom. Third, the most distinguishing characteristic of Bakhtin's dialogism is the primacy of the other over the self, with a twofold consequence: one concerns ethics and the other epistemology. In modern philosophy, the discovery of "Thou" or the primacy of the other over the self in asymmetrical reciprocity is credited to Feuerbach. It is hailed as the "Copernican revolution" of mind, ethics, and social thought. Ethically, Bakhtin's dialogism, based on heteronomy, signals the birth of a new philosophy of responsibility that challenges and transgresses the Anglo-American tradition of "rights talk." Epistemologically, it lends our welcoming ears to the credence that the other may be right – the attitude that Gadamer calls the soul of dialogical hermeneutics.

Bakunin, Mikhail (1814–76), Russian revolutionary anarchist. He lived in Western Europe in 1840–49 and again in 1861–76 after an intervening period in Western and Russian prisons and Siberian exile. Bakunin is best known for his vigorous if incoherent anarchist-socialist views. On the one hand, he claimed that the masses' "instinct for freedom" would spark the social revolution; on the other, he claimed that the revolution would be the work of a conspiratorial elite of disciplined professionals. Still, Bakunin made two significant if limited philosophic contributions.

(1) In the early 1840s he spoke of the "incessant self-immolation of the positive in the pure flame of the negative," and came to see that "flame" as a necessary dialectical component of revolutionary action. His sharpest criticism was directed not at conservative attempts to defend the existing order but rather at (Hegelian) attempts to reconcile positive and negative and "liberal" efforts to find a "modest and harmless place" for the negative within the positive. For Bakunin the negative is absolutely justified in its "constructive" elimination of the positive. Writing in German (in 1842) he exploited both senses of the word *lust*, namely "joy" and "urge," declaring that the *lust* to destroy is at the same time a creative *lust*.

(2) From 1861 until the end of his life Bakunin was committed to scientism, materialism, and atheism. But in the late 1860s he formulated a forceful critique of the political and social role of scientific elites and institutions. Individual life is concrete and particular; science is abstract and general and incapable of understanding or valuing living individuals. Instead, it tends to ignore or to exploit them. Bakunin, who had preached an anarchist revolt against church and state, now preached a "revolt of life against science, or rather against *government by science*." This was related to his anarchist critique of Marx's statism and technicism; but it raised the more general question – one of continuing relevance and urgency – of the role of scientific experts in decisions about public policy.

Bañez, Domingo (1528–1604), Spanish Dominican theologian and philosopher. Born in Valladolid, he studied at Salamanca, where he also taught for many years. As spiritual director of St. Teresa of Ávila, he exerted considerable influence on her views. He is known for his disputes with Molina concerning divine grace. Against Molina he held physical predetermination, the view that God physically determines the secondary causes of human action. This renders grace intrinsically efficacious and independent of human will and merits. He is also known for his understanding of the centrality of the act of existence (*esse*) in Thomistic metaphysics. Bañez's most important works are his commentaries on Aquinas's *Summa theologiae* and Aristotle's *On Generation and Corruption*. **See also** AQUINAS, FREE WILL PROBLEM, METAPHYSICS, MOLINA.

bargaining theory, the branch of game theory that treats agreements, e.g. wage agreements between labor and management. In the simplest bargaining problems there are two bargainers. They can jointly realize various outcomes, including the outcome that occurs if they fail to reach an agreement. Each bargainer assigns a certain amount of utility to each outcome. The question is, what outcome will they realize if they are rational? Methods of solving bargaining problems are controversial. The best-known proposals are Nash's and Kalai and Smorodinsky's. Nash proposes maximizing the product of utility gains with respect to *the disagreement point*. Kalai and Smorodinsky propose maximizing utility gains with respect to the disagreement point, subject to the constraint that the ratio of utility gains equals the ratio of greatest possible gains. These methods of selecting an outcome have been axiomatically characterized. For each method, there are certain axioms of outcome selection such that that method alone satisfies the axioms. The axioms incorporate principles of rationality from *cooperative game theory*. They focus on features of outcomes rather than bargaining strategies. For example, one axiom requires that the outcome selected be *Pareto-optimal* – i.e., be an outcome such that no alternative is better for one of the bargainers and not worse for the other.

Bargaining problems may become more complicated in several ways. First, there may be more than two bargainers. If unanimity is not required for beneficial agreements, splinter groups or *coalitions* may form. Second, the protocol for offers, counteroffers, etc., may be relevant. Then principles of *non-cooperative game theory* concerning strategies are needed to justify solutions. Third, the context of a bargaining problem may be relevant. For instance, opportunities for *side payments*, differences in bargaining power, and interpersonal comparisons of utility may influence the solution. Fourth, simplifying assumptions, such as the assumption that bargainers have *complete information* about their bargaining situation, may be discarded.

Bargaining theory is part of the philosophical study of rationality. It is also important in ethics as a foundation for contractarian theories of morality and for certain theories of distributive justice.

Barthes, Roland (1915–80), French poststructuralist literary critic and essayist. Born in Cherbourg, he suffered from numerous ailments as a child and spent much of his early life as a semi-invalid. After leaving the military, he took up several positions teaching subjects like classics, grammar, and philology. His interest in linguistics finally drew him to literature, and by the mid-1960s he had already published what would become a classic in structural analysis, *The Elements of Semiology*. Its principal message is that words are merely one kind of sign whose meaning lies in relations of difference between them. This concept was later amended to include the reading subject, and the structuring effect that the subject has on the literary work – a concept expressed later in his *S/Z* and *The Pleasure of the Text*. Barthes's most mature contributions to the poststructuralist movement were brilliant and witty interpretations of visual, tactile, and aural sign systems, culminating in the publication of several books and essays on photography, advertising, film, and cuisine. **See also** **POSTMODERN, POSTSTRUCTURALISM, SEMIOSIS, STRUCTURALISM.**

basic norm, also called *Grundnorm*, in a legal system, the norm that determines the legal validity of all other norms. The content of such an ultimate norm may provide, e.g., that norms created by a legislature or by a court are legally valid. The validity of such an ultimate norm cannot be established as a matter of social fact (such as the social fact that the norm is accepted by some group within a society). Rather, the validity of the basic norm for any given legal system must be presupposed by the validity of the norms that it legitimates as laws. The idea of a basic norm is associated with the legal philosopher Hans Kelsen. **See also** **JURISPRUDENCE, PHILOSOPHY OF LAW.**

Basilides (A.D. c.120–40), Syrian Christian gnostic teacher in Alexandria who rivaled Valentinus. He improved on Valentinus's doctrine of emanations, positing 365 (the number of days in a year) levels of existence in the Pleroma (the fullness of the Godhead), all descending from the ineffable Father. He taught that the rival God was the God of the Jews (the God of the Old Testament), who created the material world. Redemption consists in the coming of the first begotten of the Father, *Noûs* (Mind), in human form in order to release the spiritual element imprisoned within human bodies. Like other gnostics he taught that we are saved by knowledge, not faith. He apparently held to the idea of reincarnation before the restoration of all things to the Pleroma. **See also** **GNOSTICISM, VALENTINUS.**

L.P.P.

basing relation, also called the basis relation, the relation between a belief or item of knowledge and a second belief or item of knowledge when the latter is the ground (basis) of the first. It is clear that some knowledge is *indirect*, i.e. had or gained on the basis of some evidence, as opposed to direct knowledge, which (assuming there is any) is not so gained, or based. The same holds for justified belief. In one *broad* sense of the term, the basing relation is just the one connecting indirect knowledge or indirectly justified belief to the evidence: to give an account of either of the latter is to give an account of the basing relation.

There is a narrower view of the basing relation, perhaps implicit in the first. A person knows some proposition *P* on the basis of evidence or reasons only if her belief that *P* is based on the evidence or reasons, or perhaps on the possession of the evidence or reasons. The narrow basing relation is indicated by this question: where a belief that *P* constitutes indirect knowledge or justification, what is it for that *belief* to be based on the evidence or reasons that supports the knowledge or justification? The most widely favored view is that the relevant belief is based on evidence or reasons only if the belief is causally related to the belief or reasons. Proponents of this causal view differ concerning what, beyond this causal relationship, is needed by an account of the narrow basing relation.

Bataille, Georges (1897–1962), French philosopher and novelist with enormous influence on poststructuralist thought. By locating value in expenditure as opposed to accumulation, Bataille inaugurates the era of the death of the subject. He insists that individuals must transgress the limits imposed by subjectivity to escape isolation and communicate. Bataille's prewar philosophical contributions consist mainly of short essays, the most significant of which have been collected in *Visions of Excess*. These essays introduce the central idea that base matter disrupts rational subjectivity by attesting to the continuity in which individuals lose themselves. *Inner Experience* (1943), Bataille's first lengthy philosophical treatise, was followed by *Guilty* (1944) and *On Nietzsche* (1945). Together, these three works constitute Bataille's *Summa Atheologica*, which explores the play of the isolation and the dissolution of beings in terms of the experience of excess (laughter, tears, eroticism, death, sacrifice, poetry). *The Accursed Share* (1949), which he considered his most important work, is his most systematic account of the social and economic implications of expenditure. In *Erotism* (1957) and *The Tears of Eros* (1961), he focuses on the excesses of sex and death. Throughout his life, Bataille was concerned with the question of value. He located it in the excess that lacerates individuals and opens channels of communication. **See also** POSTMODERN, STRUCTURALISM. J.H.L.

Baumgarten, Alexander Gottlieb (1714–62), German philosopher. Born in Berlin, he was educated in Halle and taught at Halle (1738–40) and Frankfurt an der Oder (1740–62). Baumgarten was brought up in the Pietist circle of A. H. Francke but adopted the anti-Pietist rationalism of Wolff. He wrote textbooks in metaphysics (*Metaphysica*, 1739) and ethics (*Ethica Philosophica*, 1740; *Initia Philosophiae Practicae Prima* ["First Elements of Practical Philosophy"], 1760) on which Kant lectured. For the most part, Baumgarten did not significantly depart from Wolff, although in metaphysics he was both further and yet closer to Leibniz than was Wolff: unlike Leibniz, he argued for real physical influx, but, unlike Wolff, he did not restrict preestablished harmony to the mind-body relationship alone, but (paradoxically) reextended it to include all relations of substances.

Baumgarten's claim to fame, however, rests on his introduction of the discipline of aesthetics into German philosophy, and indeed on his introduction of the term 'aesthetics' as well. Wolff had explained pleasure as the response to the perception of perfection by means of the senses, in turn understood as clear but confused perception. Baumgarten subtly but significantly departed from Wolff by redefining our response to beauty as pleasure in the perfection of sensory perception – i.e., in the unique potential of sensory as opposed to merely conceptual representation. This concept was first introduced in his dissertation, *Meditationes Philosophicae de Nonnullis ad Poema Pertinentibus* ("Philosophical Meditations on some Matters Pertaining to Poetry," 1735), which defined a poem as a "perfect sensate discourse," and then generalized in his two-volume (but still incomplete) *Aesthetica* (1750–58). One might describe Baumgarten's aesthetics as cognitivist but no longer rationalist: while in science or logic we must always prefer discursive clarity, in art we respond with pleasure to the maximally dense (or "confused") intimation of ideas. Baumgarten's theory had a great influence on Lessing and Mendelssohn, on Kant's theory of aesthetic ideas, and even on the aesthetics of Hegel.

Bayesian. See BAYESIAN EPISTEMOLOGY, BAYESIAN RATIONALITY, CONFIRMATION.

Bayesian epistemology, philosophical work or reflection in the theory of knowledge or justified belief that uses the probability calculus in dealing with epistemological problems. The basic idea is that belief is not an all-or-nothing affair but allows for degrees. The degrees of belief (credences) of an ideally rational subject conform to the probability calculus. One theorem of the probability calculus states that the probabilities of any belief and of its negation add up to 1. A particularly useful theorem of this calculus is Bayes's theorem (named after Thomas Bayes [1701–61]); it says that the probability that a belief *b* is true, on the assumption that some evidence *e* is true, is equal to the unconditional probability of *b* being true, times the probability of *e* given *b*, divided by the unconditional probability of *e*.

The question of whether there are constraints on the unconditional (or prior) probability of a belief *b* being true divides Bayesians. Subjective Bayesians (e.g., Bruno de Finetti, Richard Jeffrey) hold that there are very few constraints on prior probabilities. A person is free to set the prior probability anywhere between 0 and 1. Prior probability assignments are governed by non-rational factors such as unconstrained choice, evolution, or socialization. Objective Bayesians (e.g., Edwin Thompson Jaynes, Roger D. Rosenkrantz), by contrast, hold that prior probabilities are uniquely determined by rational constraints. Such constraints might be a priori or empirical, and they might uniquely determine the relevant prior probabilities or simply constrain the range of rationally admissible priors. All Objective Bayesians hold that prior probabilities are determined by symmetry constraints.

Belief is not the only central epistemological notion admitting degrees. There are also gradations of confirmation, evidence, justification, coherence, and (credibility of) testimony. Bayesian epistemology promises to provide more precise analyses of these notions than much traditional epistemology, which has often treated them as if they did not admit degrees. Bayesian epistemology thus complements traditional epistemology, which in turn inspires Bayesianism.

Despite its accomplishments, some philosophers think that Bayesian epistemology rests on some dubious assumptions, for instance that we believe propositions with precise, numerical degrees of strength. But is it really possible to believe something to, say, degree .265? Another contentious assumption of Bayesian epistemology is that only degrees of belief that satisfy the probability calculus are rational. This assumption is usually motivated by the Dutch book argument, which shows that anyone whose degrees of belief do not satisfy the probability calculus will act irrationally by knowingly accepting a collection of bets guaranteed to lead to a loss. Yet the Dutch book argument, in turn, rests on the contentious assumption that it is irrational for people not to maximize their expected utility.

See also BAYES'S THEOREM, BAYESIAN RATIONALITY, BELIEF UPDATING, DEGREES OF BELIEF, DUTCH BOOK ARGUMENT, EPISTEMOLOGY, PROBABILITY, RATIONALITY. S.B.

Bayesian rationality, minimally, a property that a system of beliefs (or the believer) has in virtue of the system's conforming to the probability calculus. Bayesians differ on what "rationality" requires, but most agree that (1) beliefs come in *degrees* (of firmness); (2) these degrees of belief are (theoretically or ideally) *quantifiable;* (3) such quantification can be understood in terms of person-relative, time-indexed "credence functions" from appropriate sets of objects of belief (propositions or sentences) – each set closed under (at least) finite truth-functional combinations – into the set of real numbers; (4) at any given time *t*, a person's credence function at *t ought* to be (usually: "on pain of a Dutch book argument") a *probability* function; that is, a mapping from the given set into the real numbers in such a way that the "probability" (the value) assigned to any given object *A* in the set is greater than or equal to zero, *and* is equal to unity (= 1) if *A* is a necessary truth, *and*, for any given objects *A* and *B* in the set, if *A* and *B* are incompatible (the negation of their conjunction is a necessary truth) then the probability assigned to their disjunction is equal to the sum of the probabilities assigned to each; so that the usual propositional probability axioms impose a sort of logic on degrees of belief. If a credence function is a probability function, then it (or the believer at the given time) is "coherent."

On these matters, on *conditional* degrees of belief, and on the further constraint on rationality many Bayesians impose (that change of belief ought to accord with "conditionalization"), the reader should consult John Earman, *Bayes or Bust? A Critical Examination of Bayesian Confirmation Theory* (1992); Colin Howson and Peter Urbach, *Scientific Reasoning: The Bayesian Approach* (1989); and Richard Jeffrey, *The Logic of Decision* (1965).

Bayes's rule. See BAYES'S THEOREM.

Bayes's theorem, any of several relationships between prior and posterior probabilities or odds, especially (1)–(3) below. All of these depend upon the basic relationship (0) between contemporaneous conditional and unconditional probabilities. Non-Bayesians think these useful only in narrow ranges of cases, generally because of skepticism about accessibility or significance of priors.

According to (1), posterior probability is prior

$$(0)\quad \mathrm{pr}(hyp_1 \mid data) = \mathrm{pr}(hyp_1 \& data)/\mathrm{P}(data)$$

$$(1)\quad \mathrm{pr}(hyp_1 \mid data) = \mathrm{pr}(hyp_1) \times \frac{\mathrm{pr}(data \mid hyp_1)}{\mathrm{P}(data)}$$

$$(2)\quad \frac{\mathrm{pr}(hyp_1 \mid data)}{\mathrm{pr}(hyp_2 \mid data)} = \frac{\mathrm{pr}(hyp_1)}{\mathrm{pr}(hyp_2)} \times \frac{\mathrm{pr}(data \mid hyp_1)}{\mathrm{pr}(data \mid hyp_2)}$$

$$(3)\quad \mathrm{pr}(hyp_1 \mid data) = \frac{\mathrm{pr}(hyp_1) \times \mathrm{pr}(data \mid hyp_1)}{\sum_n \mathrm{pr}(hyp_n) \times \mathrm{pr}(data \mid hyp_n)}$$

probability times the "relevance quotient" (Carnap's term). According to (2), posterior odds are prior odds times the "likelihood ratio" (R. A. Fisher's term). Relationship (3) comes from (1) by expanding P (*data*) via the law of total probability.

Bayes's rule (4) for updating probabilities has you set your new unconditional probabilities equal to your old conditional ones when fresh certainty about data leaves probabilities conditionally upon the data unchanged. The corresponding rule (5) has you do the same for odds. In decision theory the term is used differently, for the rule 'Choose so as to maximize expectation of utility'.

$$(4)\quad \text{new}\,\mathrm{pr}(hyp_1) = \text{old}\ \mathrm{pr}(hyp_1 \mid data)$$

$$(5)\quad \frac{\text{new}\,\mathrm{pr}(hyp_1)}{\text{new}\,\mathrm{pr}(hyp_2)} = \frac{\text{old}\ \mathrm{pr}(hyp_1 \mid data)}{\text{old}\ \mathrm{pr}(hyp_2 \mid data)}$$

Bayle, Pierre (1647–1706), French philosopher who also pioneered in disinterested, critical history. A Calvinist forced into exile in 1681, Bayle nevertheless rejected the prevailing use of history as an instrument of partisan or sectarian interest. He achieved fame and notoriety with his multivolume *Dictionnaire historique et critique* (1695). For each subject covered, Bayle provided a biographical sketch and a dispassionate examination of the historical record and interpretive controversies. He also repeatedly probed the troubled and troubling boundary between reason and faith (philosophy and religion). In the article "David," the seemingly illicit conduct of God's purported agent yielded reflections on the morals of the elect and the autonomy of ethics. In "Pyrrho," Bayle argued that self-evidence, the most plausible candidate for the criterion of truth, is discredited by Christianity because some self-evident principles contradict essential Christian truths and are therefore false. Finally, provoking Leibniz's *Theodicy*, Bayle argued, most relentlessly in "Manichaeans" and "Paulicians," that there is no defensible rational solution to the problem of evil.

Bayle portrayed himself as a Christian skeptic, but others have seen instead an ironic critic of religion – a precursor of the French Enlightenment. Bayle's purely philosophical reflections support his self-assessment, since he consistently maintains that philosophy achieves not comprehension and contentment, but paradox and puzzlement. In making this case he proved to be a superb critic of philosophical systems. Some examples are "Zeno of Elea" – on space, time, and motion; "Rorarius" – on mind and body and animal mechanism; and "Spinoza" – on the perils of monism. Bayle's skepticism concerning philosophy significantly influenced Berkeley and Hume. His other important works include *Pensées diverses de la comète de 1683* (1683); *Commentaire philosophique sur ces paroles de Jesus Christ: contrain les d'entrer* (1686); *Réponse aux questions d'un provincial* (1704); and an early learned periodical, the *Nouvelles de la République des Lettres* (1684–87).

Beattie, James (1735–1803), Scottish philosopher and poet who, in criticizing Hume, widened the latter's audience. Beattie was a member of the Scottish school of common sense philosophy along with Oswald and Reid. His major work was *An Essay on the Nature and Immutability of Truth* (1771), in which he criticizes Hume for fostering skepticism and infidelity. His positive view was that the mind possesses a common sense, i.e. a power for perceiving self-evident truths. Common sense is instinctive, unalterable by education; truth is what common sense determines the mind to believe. Beattie cited Hume and then claimed that his views led to moral and religious evils. When Beattie's *Essay* was translated into German (1772), Kant could read Hume's discussions of personal identity and causation. Since these topics were not covered in Hume's *Inquiry Concerning Human Understanding*, Beattie provided Kant access to two issues in the *Treatises of Human Nature* critical to the development of transcendental idealism. **See also** HUME, SCOTTISH COMMON SENSE PHILOSOPHY. P.K.

beauty, an aesthetic property commonly thought of as a species of aesthetic value. As such, it has been variously thought to be (1) a simple, indefinable property that cannot be defined in terms of any other properties; (2) a property or set of properties of an object that makes the object capable of producing a certain sort of pleasurable experience in any suitable perceiver; or (3) whatever produces a particular sort of pleasurable experience, even though what produces the experience may vary from individual to individual. It is in this last sense that beauty is thought to be "in the eye of the beholder."

If beauty is a simple, indefinable property, as in (1), then it cannot be defined conceptually and has to be apprehended by intuition or taste. Beauty, on this account, would be a particular sort of aesthetic property. If beauty is an object's capacity to produce a special sort of pleasurable experience, as in (2), then it is necessary to say what properties provide it with this capacity. The most favored candidates for these have been formal or structural properties, such as order, symmetry, and proportion. In the *Philebus* Plato argues that the form or essence of beauty is knowable, exact, rational, and measurable. He also holds that simple geometrical shapes, simple colors, and musical notes all have "intrinsic beauty," which arouses a pure, "unmixed" pleasure in the perceiver and is unaffected by context.

In the sixteenth and seventeenth centuries many treatises were written on individual art forms, each allegedly governed by its own rules. In the eighteenth century, Hutcheson held that 'beauty' refers to an "idea raised in us," and that any object that excites this idea is beautiful. He thought that the property of the object that excites this idea is "uniformity in variety."

Kant explained the nature of beauty by analyzing judgments that something is beautiful. Such judgments refer to an experience of the perceiver. But they are not merely expressions of personal experience; we claim that others should also have the same experience, and that they should make the same judgment (i.e., judgments that something is beautiful have "universal validity"). Such judgments are disinterested – determined not by any needs or wants on the part of the perceiver, but just by contemplating the mere appearance of the object. These are judgments about an object's *free beauty*, and making them requires using only those mental capacities that all humans have by virtue of their ability to communicate with one another. Hence the pleasures experienced in response to such beauty can in principle be shared by anyone.

Some have held, as in (3), that we apply the term 'beautiful' to things because of the pleasure they give us, and not on the basis of any specific qualities an object has. Archibald Alison held that it is impossible to find any properties common to all those things we call beautiful. Santayana believed beauty is "pleasure regarded as a quality of a thing," and made no pretense that certain qualities ought to produce that pleasure.

The Greek term *to kalon*, which is often translated as 'beauty', did not refer to a thing's autonomous aesthetic value, but rather to its "excellence," which is connected with its moral worth and/or usefulness. This concept is closer to Kant's notion of *dependent beauty*, possessed by an object judged as a particular kind of thing (such as a beautiful cat or a beautiful horse), than it is to free beauty, possessed by an object judged simply on the basis of its appearance and not in terms of any concept of use.

Beauvoir, Simone de. See EXISTENTIALISM.

Beccaria, Cesare (1738–94), Italian criminologist and judicial and penal reformer. He studied in Parma and Pavia and taught political economy in Milan. Here, he met Pietro and Alessandro Verri and other Milanese intellectuals attempting to promote political, economic, and judiciary reforms. His major work, *Dei delitti e delle pene* ("On Crimes and Punishments," 1764), denounces the contemporary methods in the administration of justice and the treatment of criminals. Beccaria argues that the highest good is the greatest happiness shared by the greatest number of people; hence, actions against the state are the most serious crimes. Crimes against individuals and property are less serious, and crimes endangering public harmony are the least serious. The purposes of punishment are deterrence and the protection of society. However, the employment of torture to obtain confessions is unjust and useless: it results in acquittal of the strong and the ruthless and conviction of the weak and the innocent. Beccaria also rejects the death penalty as a war of the state against the individual. He claims that the duration and certainty of the punishment, not its intensity, most strongly affect criminals. Beccaria was influenced by Montesquieu, Rousseau, and Condillac. His major work was translated into many languages and set guidelines for revising the criminal and judicial systems of several European countries. P.Gar.

behavioralism. See JURISPRUDENCE.

behaviorism, broadly, the view that behavior is fundamental in understanding mental phenomena. The term applies both to a scientific research program in psychology and to a philosophical doctrine. Accordingly, we distinguish between scientific (psychological, methodological) behaviorism and philosophical (logical, analytical) behaviorism.

Scientific behaviorism. First propounded by the American psychologist J. B. Watson (who introduced the term in 1913) and further developed especially by C. L. Hull, E. C. Tolman, and B. F. Skinner, it departed from the introspectionist tradition by redefining the proper task of psychology as the explanation and prediction of behavior – where to explain behavior is to provide a "functional analysis" of it, i.e. to specify the independent variables (stimuli) of which the behavior (response) is lawfully a function. It insisted that all variables – including behavior as the dependent variable – must be specifiable by the experimental procedures of the natural sciences: merely introspectible, internal states of consciousness are thus excluded from the proper domain of psychology. Although some behaviorists were prepared to admit internal neurophysiological conditions among the variables ("intervening variables"), others of a more radical bent (e.g., Skinner) insisted on environmental variables alone, arguing that any relevant variations in the hypothetical inner states would themselves in general be a function of variations in (past and present) environmental conditions (as, e.g., thirst is a function of water deprivation). Although some basic responses are inherited reflexes, most are learned and integrated into complex patterns by a process of conditioning. In *classical* (*respondent*) *conditioning*, a response already under the control of a given stimulus will be elicited by new stimuli if these are repeatedly paired with the old stimulus: this is how we learn to respond to new situations. In *operant conditioning*, a response that has repeatedly been followed by a reinforcing stimulus (reward) will occur with greater frequency and will thus be "selected" over other possible responses: this is how we learn new responses. Conditioned responses can also be unlearned or "extinguished" by prolonged dissociation from the old eliciting stimuli or by repeated withholding of the reinforcing stimuli. To show how all human behavior, including "cognitive" or intelligent behavior, can be "shaped" by such processes of selective reinforcement and extinction of responses was the ultimate objective of scientific behaviorism. Grave difficulties in the way of the realization of this objective led to increasingly radical liberalization of the distinctive features of behaviorist methodology and eventually to its displacement by more cognitively oriented approaches (e.g., those inspired by information theory and by Chomsky's work in linguistics).

Philosophical behaviorism. A semantic thesis about the meaning of mentalistic expressions, it received its most sanguine formulation by the logical positivists (particularly Carnap, Hempel, and Ayer), who asserted that statements containing mentalistic expressions have the same meaning as, and are thus translatable into, some set of publicly verifiable (confirmable, testable) statements describing behavioral and bodily processes and dispositions (including verbal-behavioral dispositions). Because of the reductivist concerns expressed by the logical positivist thesis of physicalism and the unity of science, logical behaviorism (as some positivists preferred to call it) was a corollary of the thesis that psychology is ultimately (via a behavioristic analysis) reducible to physics, and that all of its statements, like those of physics, are expressible in a strictly extensional language.

Another influential formulation of philosophical behaviorism is due to Ryle (*The Concept of Mind*, 1949), whose classic critique of Cartesian dualism rests on the view that mental predicates are often used to ascribe dispositions to behave in characteristic ways; but such ascriptions, for Ryle, have the form of conditional, lawlike statements whose function is not to report the occurrence of inner states, physical or non-physical, of which behavior is the causal manifestation, but to license inferences about how the agent *would* behave *if* certain conditions obtained. To suppose that all declarative uses of mental language have a fact-stating or -reporting role at all is, for Ryle, to make a series of "category mistakes" – of which both Descartes and the logical positivists were equally guilty. Unlike the behaviorism of the positivists, Ryle's behaviorism required no physicalistic reduction of mental language, and relied instead on ordinary language descriptions of human behavior.

A further version of philosophical behaviorism can be traced to Wittgenstein (*Philosophical Investigations*, 1953), who argues that the epistemic criteria for the applicability of mentalistic terms cannot be private, introspectively accessible inner states but must instead be intersubjectively observable behavior. Unlike the previously mentioned versions of philosophical behaviorism, Wittgenstein's behaviorism seems to be consistent with metaphysical mind-body dualism, and is thus also non-reductivist.

Philosophical behaviorism underwent severe criticism in the 1950s and 1960s, especially by Chisholm, Taylor, Putnam, and Fodor. Nonetheless it still lives on in more or less attenuated forms in the work of such diverse philosophers as Quine, Dennett, Armstrong, David Lewis, U. T. Place, and Dummett. Though current "functionalism" is often referred to as the natural heir to behaviorism, functionalism (especially of the Armstrong-Lewis variety) crucially differs from behaviorism in insisting that mental predicates, while definable in terms of behavior and behavioral dispositions, nonetheless designate *inner causal states* – states that are apt to cause certain characteristic behaviors.

behaviorism, supervenient. See PHILOSOPHY OF MIND.

behavior therapy, a spectrum of behavior modification techniques applied as therapy, such as aversion therapy, extinction, modeling, redintegration, operant conditioning, and desensitization. Unlike psychotherapy, which probes a client's recollected history, behavior therapy focuses on immediate behavior, and aims to eliminate undesired behavior and produce desired behavior through methods derived from the experimental analysis of behavior and from reinforcement theory. A chronic problem with psychotherapy is that the client's past is filtered through limited and biased recollection. Behavior therapy is more mechanical, creating systems of reinforcement and conditioning that may work independently of the client's long-term memory.

Collectively, behavior-therapeutic techniques compose a motley set. Some behavior therapists adapt techniques from psychotherapy, as in covert desensitization, where verbally induced mental images are employed as reinforcers. A persistent problem with behavior therapy is that it may require repeated application. Consider aversion therapy. It consists of pairing painful or punishing stimuli with unwelcome behavior. In the absence, after therapy, of the painful stimulus, the behavior may recur because association between behavior and punishment is broken. Critics charge that behavior therapy deals with immediate disturbances and overt behavior, to the neglect of underlying problems and irrationalities.

See also **COGNITIVE PSYCHOTHERAPY**. G.A.G.

being. See HEIDEGGER, METAPHYSICS, TRANSCENDENTALS.

belief, a dispositional psychological state in virtue of which a person will assent to a proposition under certain conditions. Propositional knowledge, traditionally understood, entails belief.

A *behavioral view* implies that beliefs are just dispositions to behave in certain ways. Your believing that the stove is hot is just your being disposed to act in a manner appropriate to its being hot. The problem is that our beliefs, including their propositional content indicated by a 'that'-clause, typically explain why we do what we do. You avoid touching the stove *because* you believe that it's dangerously hot. Explaining action via beliefs refers indispensably to propositional content, but the behavioral view does not accommodate this.

A *state-object view* implies that belief consists in a special relation between a psychological state and an object of belief, what is believed. The objects of belief, traditionally understood, are abstract propositions existing independently of anyone's thinking of them. The state of believing is a *propositional attitude* involving some degree of confidence toward a propositional object of belief. Such a view allows that two persons, even separated by a long period of time, can believe the same thing. A state-object view allows that beliefs be dispositional rather than episodic, since they can exist while no action is occurring. Such a view grants, however, that one can have a disposition to act owing to believing something. Regarding mental action, a belief typically generates a disposition to *assent*, at least under appropriate circumstances, to the proposition believed. Given the central role of propositional content, however, a state-object view denies that beliefs are just dispositions to act. In addition, such a view should distinguish between dispositional believing and a mere disposition to believe. One can be merely disposed to believe many things that one does not actually believe, owing to one's lacking the appropriate psychological attitude to relevant propositional content.

Beliefs are either *occurrent* or *non-occurrent*. Occurrent belief, unlike non-occurrent belief, requires current assent to the proposition believed. If the assent is self-conscious, the belief is an *explicit* occurrent belief; if the assent is not self-conscious, the belief is an *implicit* occurrent belief. Non-occurrent beliefs permit that we do not cease to believe that 2 + 2 = 4, for instance, merely because we now happen to be thinking of something else or nothing at all.

belief revision, the process by which cognitive states change in light of new information. This topic looms large in discussions of Bayes's theorem and other approaches in decision theory. The reasons prompting belief revision are characteristically epistemic; they concern such notions as quality of evidence and the tendency to yield truths. Many different rules have been proposed for updating one's belief set. In general, belief revision typically balances risk of error against information increase. Belief revision is widely thought to proceed either by expansion or by conceptual revision. Expansion occurs in virtue of new observations; a belief is changed, or a new belief established, when a hypothesis (or provisional belief) is supported by evidence whose probability is high enough to meet a favored criterion of epistemic warrant. The hypothesis then becomes part of the existing belief corpus, or is sufficient to prompt revision. Conceptual revision occurs when appropriate changes are made in theoretical assumptions – in accordance with such principles as simplicity and explanatory or predictive power – by which the corpus is organized. In actual cases, we tend to revise beliefs with an eye toward advancing the best comprehensive explanation in the relevant cognitive domain. **See also** BAYESIAN RATIONALITY, COHERENTISM, EPISTEMOLOGY, FOUNDATIONALISM, REFLECTIVE EQUILIBRIUM, REVISABILITY. J.D.T.

belief updating, the process by which a belief system is altered in response to a local change. Doxastic states can be represented in the full-belief or the partial-belief framework. In the full-belief framework, an agent's doxastic state is represented by a set of propositions the agent believes. The static norms associated with this framework are spelled out by formal logic: typically it is held that the belief set must be consistent. An example of such a norm is that one ought not simultaneously believe p, if p then q, and not-q. The question of rational belief updating is the question of how one's entire belief set ought to respond to the addition or removal of a particular belief, or both, as when an individual revises a belief in p to a belief in $\sim p$. There is a technical distinction between *belief revision*, which concerns attaining new information about a static world, and *belief updating*, which concerns bringing one's beliefs up to date with a changing world; this entry concerns the former.

When we are dealing with attaining new information about a static world, the goal of rational belief revision is to maintain consistency given the particular change, while including as large a subset of the old beliefs as is reasonable. The standard formal framework for representing the dynamic norms governing this change is the AGM model (pioneered by Carlos Alchourrón, Peter Gärdenfors, and David Makinson), which assumes that a belief state must be closed under logical consequence. The three primary operations in the AGM model are expansion, in which a proposition is added to the belief set; contraction, in which a proposition is removed from the belief set and a subset that does not imply that proposition is formed in a precise way; and revision, in which a proposition is added to the belief set and the belief set is altered to preserve logical consistency. These operations can also be represented in a framework in which a belief set is thought of as a set of possible worlds.

AGM concerns belief revision rather than belief updating; related postulates governing belief updating are proposed by Hirofumi Katsuno and Alberto O. Mendelzon. AGM also primarily concerns "one-shot" belief revision rather than iterated belief revision in response to a sequence of pieces of new information. There is currently no universally accepted extension of AGM to cover iterated belief revision, but the framework of Darwiche and Pearl has been influential. In particular, these authors use a richer framework than belief sets, that of epistemic states, which includes "conditional beliefs": beliefs that one is prepared to adopt conditioned on any hypothetical evidence.

In the partial-belief framework, an agent's doxastic state is represented by an assignment of credences or degrees of belief to propositions. The static norms associated with this framework are spelled out by the probability calculus. An example of such a norm is additivity: if one assigns $\mathrm{Cr}(p) = a$ and $\mathrm{Cr}(q) = b$, then one ought to assign $\mathrm{Cr}(p \vee q) = a + b$. The question of rational credence updating is the question of how one's credences ought to respond to learning new information. As in the full-belief framework, there is a distinction between learning information about a static world and learning new information about a changing world, and this entry concerns the former.

When one is dealing with a static world, the goal of rational credence updating is to incorporate both the new information and its effect on the rest of the agent's credences. Learning new information is typically represented by assigning credence 1 to a particular proposition, and it is typically held that one ought to conditionalize on that proposition: to adopt credences equivalent to one's prior conditional credences (conditional on the proposition). However, a more general notion of updating is given by Jeffrey conditionalization.

Beneke, Friedrich Eduard (1798–1854), German philosopher who was influenced by Herbart and English empiricism and criticized rationalistic metaphysics. He taught at Berlin and published some eighteen books in philosophy. His major work was *Lehrbuch der Psychologie als Naturwis-senschaft* (1833). He wrote a critical study of Kant's *Critique of Pure Reason* and another on his moral theory; other works included *Psychologie Skizzen* (1825), *Metaphysik und Religionphilosophie* (1840), and *Die neue Psychologie* (1845). The "new psychology" developed by Beneke held that the hypostatization of "faculties" led to a mythical psychology. He proposed a method that would yield a natural science of the soul or, in effect, an associationist psychology. Influenced by the British empiricists, he conceived the elements of mental life as dynamic, active processes or impulses (*Trieben*). These "elementary faculties," originally activated by stimuli, generate the substantial unity of the nature of the psychic by their persistence as traces, as well as by their reciprocal adjustment in relation to the continuous production of new forces.

In what Beneke called "pragmatic psychology," the psyche is a bundle of impulses, forces, and functions. Psychological theory should rest on inductive analyses of the facts of inner perception. This, in turn, is the foundation of the philosophical disciplines of logic, ethics, metaphysics, and philosophy of religion. In this regard, Beneke held a psychologism. He agreed with Herbart that psychology must be based on inner experience and must eschew metaphysical speculation, but rejected Herbart's mathematical reductionism. Beneke sought to create a "pragmatic philosophy" based on his psychology. In his last years he contributed to pedagogic theory.

Bennett, Jonathan (b.1930), New Zealand-American philosopher best known for his collegial approach to early modern philosophy, in which one approaches historical figures in the spirit of a colleague, with the goal of learning from them and interpreting them in a way that expresses their intentions while making them as philosophically interesting as possible. Bennett's thinking has been influenced by Spinoza, Hume, and Frege and, among his contemporaries, by Arthur Prior, Peter Strawson, W. V. O. Quine, and David Lewis.

His publications include five books in the history of philosophy: *Kant's Analytic* (1966); *Locke, Berkeley, Hume: Central Themes* (1971); *Kant's Dialectic* (1974); *A Study of Spinoza's Ethics* (1984); and *Learning from Six Philosophers* (2001). He is coeditor and translator of Leibniz's *New Essays on Human Understanding* (1981, 1996). Bennett has written five other books: *Rationality* (1964, 1989); *Linguistic Behaviour* (1976, 1990); *Events and Their Names* (1988), which explores the nature of events and our terms for them, arguing that causation is best understood as a relation between facts rather than events; *The Act Itself* (1995), which explores the pros and cons of consequentialism, developing a powerful new account of the distinction between doing and allowing harm; and *A Philosophical Guide to Conditionals* (2003), which analyzes indicative and subjunctive conditionals, and argues that a unified account of the two cannot be given. In addition, he has published more than eighty articles.

Bennett has recently been engaged in preparing versions of early modern philosophy texts that are easy to read, while leaving intact the main arguments, doctrines, and lines of thought. These can be found at www.earlymoderntexts.com/. Bennett was educated in New Zealand and at Oxford University and also holds a Litt.D. degree from the University of Cambridge. He has taught at the University of Cambridge (1956–68), Simon Fraser University (1968–70), the University of British Columbia (1970–79), and Syracuse University (1979–97). F.H.-S.

Bentham, Jeremy (1748–1832), British philosopher of ethics and political-legal theory. Born in London, he entered Queen's College, Oxford, at age twelve, and after graduation entered Lincoln's Inn to study law. He was admitted to the bar in 1767 but never practiced. He spent his life writing, advocating changes along utilitarian lines (maximal happiness for everyone affected) of the whole legal system, especially the criminal law. He had a strong influence on changes in the British law of evidence; in the abolition of laws permitting imprisonment for indebtedness; in the reform of parliamentary representation; in the formation of a civil service recruited by examination; and in much else. His major work published during his lifetime was *An Introduction to the Principles of Morals and Legislation* (1789). He became head of a "radical" group including James Mill and J. S. Mill, and founded the *Westminster Review* and University College, London (where his embalmed body still reposes in a closet). He was a friend of Catherine of Russia and John Quincy Adams, and was made a citizen of France in 1792.

Pleasure, he said, is the only good, and pain the only evil: "else the words good and evil have no meaning." He gives a list of examples of what he means by 'pleasure': pleasures of taste, smell, or touch; of acquiring property; of learning that one has the goodwill of others; of power; of a view of the pleasures of those one cares about. Bentham was also a psychological hedonist: pleasures and pains determine what we do. Take pain. Your state of mind may be painful now (at the time just prior to action) because it includes the expectation of the pain (say) of being burned; the present pain (or the expectation of later pain – Bentham is undecided which) motivates action to prevent being burned. One of a person's pleasures, however, may be sympathetic enjoyment of the well-being of another. So it seems one can be motivated by the prospect of the happiness of another. His psychology here is not incompatible with altruistic motivation.

Bentham's critical utilitarianism lies in his claim that any action, or measure of government, *ought* to be taken if and only if it tends to augment the happiness of everyone affected – not at all a novel principle, historically. When "thus interpreted, the words *ought*, and *right* and *wrong* . . . have a meaning: when otherwise, they have none." Bentham evidently did not mean this statement as a purely linguistic point about the actual meaning of moral terms. Neither can this principle be *proved;* it is a first principle from which all proofs proceed. What kind of reason, then, can he offer in its support? At one point he says that the principle of utility, at least unconsciously, governs the judgment of "every thinking man . . . unavoidably." But his chief answer is his critique of a widely held principle that a person properly calls an act wrong if (when informed of the facts) he *disapproves* of it. (Bentham cites other language as coming to the same thesis: talk of a "moral sense," or common sense, or the understanding, or the law of nature, or right reason, or the "fitness of things.") He says that this is no principle at all, since a "principle is something that points out some external consideration, as a means of warranting and guiding the internal sentiments of approbation." The alleged principle also allows for widespread disagreement about what is moral.

So far, Bentham's proposal has not told us exactly how to determine whether an action or social measure is right or wrong. Bentham suggests a hedonic calculus: in comparing two actions under consideration, we count up the pleasures or pains each will probably produce – how intense, how long-lasting, whether near or remote, including any derivative later pleasures or pains that may be caused – and sum them up for all persons who will be affected. Evidently these directions can provide at best only approximate results. We are in no position to decide whether one pleasure for one hour is greater than another pleasure for half an hour, even when they are both pleasures of one person who can compare them. How much more when the pleasures are of different persons? Still, we can make judgments important for the theory of punishment: whether a blow in the face with no lasting damage for one person is more or less painful than fifty lashes for his assailant!

Bentham has been much criticized because he thought that two pleasures are equal in value, if they are equally intense, enduring, etc. As he said, "Quantity of pleasure being equal, pushpin is as good as poetry." It has been thought (e.g., by J. S. Mill) that some pleasures, especially intellectual ones, are higher and deserve to count more. But it may be replied that the so-called higher pleasures are more enduring, are less likely to be followed by satiety, and open up new horizons of enjoyment; and when these facts are taken into account, it is not clear that there is need to accord higher status to intellectual pleasures as such.

A major goal of Bentham's was to apply to the criminal law his principle of maximizing the general utility. Bentham thought there should be no punishment of an offense if it is not injurious to someone. So how much punishment should there be? The least amount the effect of which will result in a greater degree of happiness, overall. The benefit of punishment is primarily deterrence, by attaching to the thought of a given act the thought of the painful sanction – which will deter both the past and prospective lawbreakers. The punishment, then, must be severe enough to outweigh the benefit of the offense to the agent, making allowance, by addition, for the uncertainty that the punishment will actually occur.

There are some harmful acts, however, that it is not beneficial to punish. One is an act needful to produce a greater benefit, or avoid a serious evil, for the agent. Others are those which a penal prohibition could not deter: when the law is unpublished or the agent is insane or an infant. In some cases society need feel no alarm about the future actions of the agent. Thus, an act is criminal only if intentional, and the agent is excused if he acted on the basis of beliefs such that, were they true, the act would have caused no harm, unless these beliefs were culpable in the sense that they would not have been held by a person of ordinary prudence or benevolence. The propriety of punishing an act also depends somewhat on its motive, although no motive – e.g., sexual desire, curiosity, wanting money, love of reputation – is bad in itself. Yet the propriety of punishment is affected by the presence of some motivations that enhance public security because it is unlikely that they – e.g., sympathetic concern or concern for reputation – will lead to bad intentional acts. When a given motive leads to a bad intention, it is usually because of the weakness of motives like sympathy, concern for avoiding punishment, or respect for law.

In general, the sanction of *moral* criticism should take lines roughly similar to those of the ideal law. But there are some forms of behavior, e.g. imprudence or fornication, which the law is hardly suited to punish, that can be sanctioned by morality.

The business of the moral philosopher is censorial: to say what the law, or morality, *ought* to be. To say what *is* the law is a different matter: what it is, is the *commands* of the sovereign, defined as one whom the public, in general, habitually obeys. As consisting of commands, it is imperatival. The imperatives may be addressed to the public, as in 'Let no one steal', or to judges, as in 'Let a judge sentence anyone who steals to be hanged'. It may be thought that there is a third part, an explanation, say, of what is a person's property; but this can be absorbed in the imperatival part, since the designations of property are just imperatives about who is to be free to do what. Why should anyone obey the actual laws? Bentham's answer is that one should do so if and only if it promises to maximize the general happiness. He eschews contract theories of political obligation: individuals now alive never contracted, and so how are they bound? He also opposes appeal to natural rights. If what are often mentioned as natural rights were taken seriously, no government could survive: it could not tax, require military service, etc. Nor does he accept appeal to "natural law," as if, once some law is shown to be immoral, it can be said to be not really law. That would be absurd.

Berdyaev, Nicolas (1874–1948), Russian religious thinker. He began as a "Kantian Marxist" in epistemology, ethical theory, and philosophy of history, but soon turned away from Marxism (although he continued to accept Marx's critique of capitalism) toward a theistic philosophy of existence stressing the values of creativity and "meonic" freedom – a freedom allegedly prior to all being, including that of God. In exile after 1922, Berdyaev appears to have been the first to grasp clearly (in the early 1920s) that the Marxist view of historical time involves a morally unacceptable devaluing and instrumentalizing of the historical *present* (including living persons) for the sake of the remote *future* end of a perfected communist society. Berdyaev rejects the Marxist position on both Christian and Kantian grounds, as a violation of the intrinsic value of human persons. He sees the historical order as marked by inescapable tragedy, and welcomes the "end of history" as an "overcoming" of objective historical time by subjective "existential" time with its free, unobjectified creativity. For Berdyaev the "world of objects" – physical things, laws of nature, social institutions, and human roles and relationships – is a pervasive threat to "free spiritual creativity." Yet such creativity appears to be subject to inevitable frustration, since its outward embodiments are always "partial and fragmentary" and no "outward action" can escape ultimate "tragic failure." Russian Orthodox traditionalists condemned Berdyaev for claiming that all creation is a "*divine-human* process" and for denying God's omnipotence, but such Western process theologians as Hartshorne find Berdyaev's position highly congenial. **See also** RUSSIAN PHILOSOPHY. G.L.K.

Bergmann, Gustav (1906–87), Austrian philosopher, the youngest member of the Vienna Circle. Born in Vienna, he received his doctorate in mathematics in 1928 from the University of Vienna. Originally influenced by logical positivism, he became a phenomenalist who also posited mental acts irreducible to sense-data (see his *The Metaphysics of Logical Positivism*, 1954). Although he eventually rejected phenomenalism, his ontology of material objects remained structurally phenomenalistic. Bergmann's world is one of momentary bare (i.e., nature-less) particulars exemplifying (phenomenally) simple universals, relational as well as non-relational. Some of these universals are non-mental, such as color properties and spatial relations, while others, such as the "intentional characters" in virtue of which some particulars (mental acts) intend or represent the facts that are their "objects," are mental. Bergmann insisted that the world is independent of both our experience of it and our thought and discourse about it: he claimed that the connection of exemplification and even the propositional connectives and quantifiers are mind-independent (see *Meaning and Existence*, 1959; *Logic and Reality*, 1964; and *Realism: A Critique of Brentano and Meinong*, 1967).

Such extreme realism produced many criticisms of his philosophy that are only finally addressed in Bergmann's recently, and posthumously, published *New Foundations of Ontology* (1992), in which he concedes that his atomistic approach to ontology has inevitable limitations and proposes a way of squaring this insight with his thoroughgoing realism.

Bergson, Henri Louis (1859–1941), French philosopher, the most influential of the first half of the twentieth century. Born in Paris and educated at the prestigious École Normale Supérieure, he began his teaching career at Clermont-Ferrand in 1884 and was called in 1900 to the Collège de France, where his lectures enjoyed unparalleled success until his retirement in 1921. Ideally placed in *la belle époque* of prewar Paris, his ideas influenced a broad spectrum of artistic, literary, social, and political movements. In 1918 he received the Légion d'honneur and was admitted into the French Academy. From 1922 through 1925 he participated in the League of Nations, presiding over the creation of what was later to become UNESCO. Forced by crippling arthritis into virtual seclusion during his later years, Bergson was awarded the Nobel Prize in Literature in 1928.

Initially a disciple of Spencer, Bergson broke with him after a careful examination of Spencer's concept of time and mechanistic positivism. Following a deeply entrenched tradition in Western thought, Spencer treats time (on an analogy with space) as a series of discrete numerical units: instants, seconds, minutes. When confronted with experience, however – especially with that of our own psychological states – such concepts are, Bergson concludes, patently inadequate. Real duration, unlike clock time, is qualitative, dynamic, irreversible. It cannot be "spatialized" without being deformed. It gives rise in us, moreover, to free acts, which, being qualitative and spontaneous, cannot be predicted.

Bergson's dramatic contrast of real duration and geometrical space, first developed in *Time and Free Will* (1890), was followed in 1896 by the mind-body theory of *Matter and Memory*. He argues here that the brain is not a locale for thought but a motor organ that, receiving stimuli from its environment, may respond with adaptive behavior. To his psychological and metaphysical distinction between duration and space Bergson adds, in *An Introduction to Metaphysics* (1903), an important epistemological distinction between intuition and analysis. Intuition probes the flow of duration in its concreteness; analysis breaks up duration into static, fragmentary concepts.

In *Creative Evolution* (1907), his best-known work, Bergson argues against both Lamarck and Darwin, urging that biological evolution is impelled by a vital impetus or *élan vital* that drives life to overcome the downward entropic drift of matter. Biological organisms, unlike dice, must compete and survive as they undergo permutations; hence the unresolved dilemma of Darwinism. Either mutations occur one or a few at a time (in which case how can they be "saved up" to constitute new organs?) or they occur all at once (in which case one has a "miracle").

Bergson's vitalism, popular in literary circles, was not accepted by many scientists or philosophers. His most general contention, however – that biological evolution is not consistent with or even well served by a mechanistic philosophy – was broadly appreciated and to many seemed convincing. This aspect of Bergson's writings influenced thinkers as diverse as Lloyd Morgan, Alexis Carrel, Sewall Wright, Pierre Teilhard de Chardin, and A. N. Whitehead.

The contrasts in terms of which Bergson developed his thought (duration/space, intuition/analysis, life/entropy) are replaced in *The Two Sources of Morality and Religion* (1932) by a new duality, that of the "open" and the "closed." The Judeo-Christian tradition, he contends, if it has embraced in its history both the open society and the closed society, exhibits in its great saints and mystics a profound opening out of the human spirit toward all humanity. Bergson's distinction between the open and the closed society was popularized by Karl Popper in *The Open Society and Its Enemies*.

While it has attracted serious criticism, Bergson's philosophy has also significantly affected subsequent thinkers. Novelists as diverse as Nikos Kazantzakis, Marcel Proust, and William Faulkner; poets as unlike as Charles Péguy, Robert Frost, and Antonio Machado; and psychologists as dissimilar as Pierre Janet and Jean Piaget were to profit significantly from his explorations of duration, conceptualization, and memory. Both French existentialism and American process philosophy bear the imprint of his thought.

Berkeley, George (1685–1753), Irish philosopher and bishop in the Anglican Church of Ireland, one of the three great British empiricists along with Locke and Hume. He developed novel and influential views on the visual perception of distance and size, and an idealist metaphysical system that he defended partly on the seemingly paradoxical ground that it was the best defense of common sense and safeguard against skepticism.

Berkeley studied at Trinity College, Dublin, from which he graduated at nineteen. He was elected to a fellowship at Trinity in 1707, and did the bulk of his philosophical writing between that year and 1713. He was made dean of Derry in 1724, following extensive traveling on the Continent; he spent the years 1728–32 in Rhode Island, waiting in vain for promised Crown funds to establish a college in Bermuda. He was made bishop of Cloyne, Ireland, in 1734, and he remained there as a cleric for nearly the remainder of his life.

Berkeley's first major publication, the *Essay Towards a New Theory of Vision* (1709), is principally a work in the psychology of vision, though it has important philosophical presuppositions and implications. Berkeley's theory of vision became something like the received view on the topic for nearly two hundred years and is a landmark work in the history of psychology. The work is devoted to three connected matters: how do we see, or visually estimate, the distances of objects from ourselves, the situation or place at which objects are located, and the magnitude of such objects?

Earlier views, such as those of Descartes, Malebranche, and Molyneux, are rejected on the ground that their answers to the above questions allow that a person can see the distance of an object without having first learned to correlate visual and other cues. This was supposedly done by a kind of natural geometry, a computation of the distance by determining the altitude of a triangle formed by light rays from the object and the line extending from one retina to the other. On the contrary, Berkeley holds that it is clear that seeing distance is something one learns to do through trial and error, mainly by correlating cues that suggest distance: the distinctness or confusion of the visual appearance; the feelings received when the eyes turn; and the sensations attending the straining of the eyes. None of these bears any necessary connection to distance.

Berkeley infers from this account that a person born blind and later given sight would not be able to tell by sight alone the distances objects were from her, nor tell the difference between a sphere and a cube. He also argues that in visually estimating distance, one is really estimating which tangible ideas one would likely experience if one were to take steps to approach the object. Not that these tangible ideas are themselves necessarily connected to the visual appearances. Instead, Berkeley holds that tangible and visual ideas are entirely heterogeneous; i.e., they are numerically and specifically distinct. The latter is a philosophical consequence of Berkeley's theory of vision, which is sharply at odds with a central doctrine of

Locke's *Essay*, namely, that some ideas are common to both sight and touch.

Locke's doctrines also receive a great deal of attention in the *Principles of Human Knowledge* (1710). Here Berkeley considers the doctrine of abstract general ideas, which he finds in Book III of Locke's *Essay*. He argues against such ideas partly on the ground that we cannot engage in the process of abstraction, partly on the ground that some abstract ideas are impossible objects, and also on the ground that such ideas are not needed for either language learning or language use. These arguments are of fundamental importance for Berkeley, since he thinks that the doctrine of abstract ideas helps to support metaphysical realism, absolute space, absolute motion, and absolute time (*Principles*, 5, 100, 110–11), as well as the view that some ideas are common to sight and touch (*New Theory*, 123). All of these doctrines Berkeley holds to be mistaken, and the first is in direct conflict with his idealism. Hence, it is important for him to undermine any support these doctrines might receive from the abstract ideas thesis.

Berkeleyan idealism is the view that the only existing entities are finite and infinite perceivers, each of which is a spirit or mental substance, and entities that are perceived. Such a thesis implies that ordinary physical objects exist if and only if they are perceived, something Berkeley encapsulates in the *esse est percipi* principle: for all sensible objects, i.e. objects capable of being perceived, their being is to be perceived. He gives essentially two arguments for this thesis. First, he holds that every physical object is just a collection of sensible qualities, and that every sensible quality is an idea. So physical objects are just collections of sensible ideas. No *idea* can exist unperceived, something everyone in the period would have granted. Hence, no physical object can exist unperceived. The second argument is the so-called master argument of *Principles* 22–24. There Berkeley argues that one cannot conceive a sensible object existing unperceived, because if one attempts to do this one must thereby conceive that very object. He concludes from this that no such object can exist "without the mind," i.e. wholly unperceived.

Many of Berkeley's opponents would have held instead that a physical object is best analyzed as a material *substratum*, in which some sensible qualities inhere. So Berkeley spends some effort arguing against material substrata or what he sometimes calls matter. His principal argument is that a sensible quality cannot inhere in matter, because a sensible quality is an idea, and surely an idea cannot exist except in a mind. This argument would be decisive if it were true that each sensible quality is an idea. Unfortunately, Berkeley gives no argument whatever for this contention in the *Principles*, and for that reason Berkeleyan idealism is not there well founded. Nor does the master argument fare much better, for there Berkeley seems to require a premise asserting that if an object is *conceived*, then that object is *perceived*. Yet such a premise is highly dubious.

Probably Berkeley realized that his case for idealism had not been successful, and certainly he was stung by the poor reception of the *Principles*. His next book, *Three Dialogues Between Hylas and Philonous* (1713), is aimed at rectifying these matters. There he argues at length for the thesis that each sensible quality is an idea. The master argument is repeated, but it is unnecessary if every sensible quality is an idea.

In the *Dialogues* Berkeley is also much concerned to combat skepticism and defend common sense. He argues that *representative realism* as held by Locke leads to skepticism regarding the external world and this, Berkeley thinks, helps to support atheism and free thinking in religion. He also argues, more directly, that representative realism is false. Such a thesis incorporates the claim that *some* sensible ideas represent real qualities in objects, the so-called primary qualities. But Berkeley argues that a sensible idea can be *like* nothing but another idea, and so ideas cannot represent qualities in objects. In this way, Berkeley eliminates one main support of skepticism, and to that extent helps to support the commonsensical idea that we gain knowledge of the existence and nature of ordinary physical objects by means of perception.

Berkeley's positive views in epistemology are usually interpreted as a version of foundationalism. That is, he is generally thought to have defended the view that beliefs about currently perceived ideas are basic beliefs, beliefs that are immediately and non-inferentially justified or that count as pieces of immediate knowledge, and that all other justified beliefs in contingent propositions are justified by being somehow based upon the basic beliefs. Indeed, such a foundationalist doctrine is often taken to help define empiricism, held in common by Locke, Berkeley, and Hume. But whatever the merits of such a view as an interpretation of Locke or Hume, it is not Berkeley's theory. This is because he allows that perceivers often have immediate and non-inferential justified beliefs, and knowledge, about physical objects. Hence, Berkeley accepts a version of foundationalism that allows for basic beliefs quite different from just beliefs about one's currently perceived ideas. Indeed, he goes so far as to maintain that such physical object beliefs are often certain, something neither Locke nor Hume would accept.

In arguing against the existence of matter, Berkeley also maintains that we literally have no coherent concept of such stuff because we cannot have any sensible idea of it. Parity of reasoning would seem to dictate that Berkeley should reject mental substance as well, thereby threatening his idealism from another quarter. Berkeley is sensitive to this line of reasoning, and replies that while we have no idea of the self, we do have some *notion* of the self, i.e. some less-than-complete concept. He argues that a person gains some immediate knowledge of the existence and nature of herself in a *reflex act;* that is, when she is perceiving something she is also conscious that something is engaging in this perception, and this is sufficient for knowledge of that perceiving entity.

To complement his idealism, Berkeley worked out a version of scientific instrumentalism, both in the *Principles* and in a later Latin work, *De Motu* (1721), a doctrine that anticipates the views of Mach. In the *Dialogues* he tries to show how his idealism is consistent with the biblical account of the creation, and consistent as well with common sense.

Three later works of Berkeley's gained him an enormous amount of attention. *Alciphron* (1734) was written while Berkeley was in Rhode Island, and is a philosophical defense of Christian doctrine. It also contains some additional comments on perception, supplementing earlier work on that topic. *The Analyst* (1734) contains trenchant criticism of the method of fluxions in differential calculus, and it set off a flurry of pamphlet replies to Berkeley's criticisms, to which Berkeley responded in his *A Defense of Free Thinking in Mathematics. Siris* (1744) contains a detailed account of the medicinal values of tar-water, water boiled with the bark of certain trees. This book also contains a defense of a sort of corpuscularian philosophy that seems to be at odds with the idealism elaborated in the earlier works for which Berkeley is now famous.

In the years 1707–1708, the youthful Berkeley kept a series of notebooks in which he worked out his ideas in philosophy and mathematics. These books, now known as the *Philosophical Commentaries*, provide the student of Berkeley with the rare opportunity to see a great philosopher's thought in development.

Berlin, Isaiah (1909–97), British philosopher and historian of ideas. He is widely acclaimed for his doctrine of radical objective pluralism; his writings on liberty; his modification, refinement, and defense of traditional liberalism against the totalitarian doctrines of the twentieth century (not least Marxism-Leninism); and his brilliant and illuminating studies in the history of ideas from Machiavelli and Vico to Marx and Sorel. A founding father with Austin, Ayer, and others of Oxford philosophy in the 1930s, he published several influential papers in its general spirit, but, without abandoning its empirical approach, he came increasingly to dissent from what seemed to him its unduly barren, doctrinaire, and truth-denying tendencies. From the 1950s onward he broke away to devote himself principally to social and political philosophy and to the study of general ideas.

His two most important contributions in social and political theory, brought together with two other valuable essays in *Four Essays on Liberty* (1969), are "Historical Inevitability" (1954) and his 1958 inaugural lecture as Chichele Professor of Social and Political Theory at Oxford, "Two Concepts of Liberty." The first is a bold and decisive attack on historical determinism and moral relativism and subjectivism and a ringing endorsement of the role of free will and responsibility in human history. The second contains Berlin's enormously influential attempt to distinguish clearly between "negative" and "positive" liberty. Negative liberty, foreshadowed by such thinkers as J. S. Mill, Constant, and above all Herzen, consists in making minimal assumptions about the ultimate nature and needs of the subject, in ensuring a minimum of external interference by authority of any provenance, and in leaving open as large a field for free individual choice as is consonant with a minimum of social organization and order. Positive liberty, associated with monist and voluntarist thinkers of all kinds, not least Hegel, the German Idealists, and their historical progeny, begins with the notion of self-mastery and proceeds to make dogmatic and far-reaching metaphysical assumptions about the essence of the subject. It then deduces from these the proper paths to freedom and, finally, seeks to drive flesh-and-blood individuals down these preordained paths, whether they wish it or not, within the framework of a tight-knit centralized state under the irrefragable rule of rational experts, thus perverting what begins as a legitimate human ideal, i.e. positive self-direction and self-mastery, into a tyranny. "Two Concepts of Liberty" also sets out to disentangle liberty in either of these senses from other ends, such as the craving for recognition, the need to belong, or human solidarity, fraternity, or equality.

Berlin's work in the history of ideas is of a piece with his other writings. *Vico and Herder* (1976) presents the emergence of that historicism and pluralism which shook the two-thousand-year-old monist rationalist faith in a unified body of truth regarding all questions of fact and principle in all fields of human knowledge. From this profound intellectual overturn, Berlin traces in subsequent volumes of essays, such as *Against the Current* (1979), *The Crooked Timber of Humanity* (1990), and *The Sense of Reality* (1996), the growth of some of the principal intellectual movements that mark our era, among them nationalism, fascism, relativism, subjectivism, nihilism, voluntarism, and existentialism. He also presents with persuasiveness and clarity that peculiar objective pluralism which he identified and made his own. There is an irreducible plurality of objective human values, many of which are incompatible with one another; hence the ineluctable need for absolute choices by individuals and groups, a need that confers supreme value upon, and forms one of the major justifications of, his conception of negative liberty; hence, too, his insistence that utopia, namely a world where all valid human ends and objective values are simultaneously realized in an ultimate synthesis, is a conceptual impossibility.

While he was not himself founder of any definable school or movement, Berlin's influence as a philosopher and as a human being has been immense, not least on a variety of distinguished thinkers such as Stuart Hampshire, Charles Taylor, Bernard Williams, Richard Wollheim, Gerry Cohen, Steven Lukes, David Pears, and many others. His general intellectual and moral impact on the life of the twentieth century as writer, diplomat, patron of music and the arts, international academic elder statesman, loved and trusted friend to the great and the humble, and dazzling lecturer, conversationalist, and *anima-teur des idées*, will furnish inexhaustible material to future historians.

Bernard of Chartres (fl. 1114–26), French philosopher. He was first a teacher (1114–19) and later chancellor (1119–26) of the cathedral school at Chartres, which was then an active center of learning in the liberal arts and philosophy. Bernard himself was renowned as a grammarian, i.e. as an expositor of difficult texts, and as a teacher of Plato. None of his works has survived whole, and only three fragments are preserved in works by others. He is now best known for an image recorded both by his student, John of Salisbury, and by William of Conches. In Bernard's image, he and all his medieval contemporaries were in relation to the ancient authors like "dwarfs sitting on the shoulders of giants." John of Salisbury takes the image to mean both that the medievals could see more and further than the ancients, and that they could do so only because they had been lifted up by such powerful predecessors. M.D.J.

Bernard of Clairvaux, Saint (1090–1153), French Cistercian monk, mystic, and religious leader. He is most noted for his doctrine of Christian humility and his depiction of the mystical experience, which exerted considerable influence on later Christian mystics. Educated in France, he entered the monastery at Cîteaux in 1112, and three years later founded a daughter monastery at Clairvaux.

According to Bernard, honest self-knowledge should reveal the extent to which we fail to be what we should be in the eyes of God. That self-knowledge should lead us to curb our pride and so become more humble. Humility is necessary for spiritual purification, which in turn is necessary for contemplation of God, the highest form of which is union with God. Consistent with orthodox Christian doctrine, Bernard maintains that mystical union does not entail identity. One does not become God; rather, one's will and God's will come into complete conformity.

See also MYSTICISM. W.E.M.

Bernoulli's theorem, also called the (weak) law of large numbers, the principle that if a series of trials is repeated n times where (a) there are two possible outcomes, 0 and 1, on each trial, (b) the probability p of 0 is the same on each trial, and (c) this probability is independent of the outcome of other trials, then, for arbitrary positive ε, as the number n of trials is increased, the probability that the absolute value $|r/n - p|$ of the difference between the relative frequency r/n of 0's in the n trials and p is less than ε approaches 1. The first proof of this theorem was given by Jakob Bernoulli in Part IV of his posthumously published *Ars Conjectandi* of 1713. Simplifications were later constructed and his result has been generalized in a series of "weak laws of large numbers." Although Bernoulli's theorem derives a conclusion about the probability of the relative frequency *r/n* of 0's for large *n* of trials given the value of *p*, in *Ars Conjectandi* and correspondence with Leibniz, Bernoulli thought it could be used to reason from information about *r/n* to the value of *p* when the latter is unknown. Speculation persists as to whether Bernoulli anticipated the inverse inference of Bayes, the confidence interval estimation of Peirce, J. Neyman, and E. S. Pearson, or the fiducial argument of R. A. Fisher. **See also** PROBABILITY. I.L.

Berry's paradox. See SEMANTIC PARADOXES.

Bertrand's box paradox, a puzzle concerning conditional probability. Imagine three boxes with two drawers apiece. Each drawer of the first box contains a gold medal. Each drawer of the second contains a silver medal. One drawer of the third contains a gold medal, and the other a silver medal. At random, a box is selected and one of its drawers is opened. If a gold medal appears, what is the probability that the third box was selected? The probability seems to be ½, because the box is either the first or the third, and they seem equally probable. But a gold medal is less probable from the third box than from the first, so the third box is actually less probable than the first. By Bayes's theorem its probability is ⅓. Joseph Bertrand, a French mathematician, published the paradox in *Calcul des probabilités* ("Calculus of Probabilities," 1889). **See also** BAYES'S THEOREM, PROBABILITY. P.We.

Bertrand's paradox, an inconsistency arising from the classical definition of an event's probability as the number of favorable cases divided by the number of possible cases. Given a circle, a chord is selected at random. What is the probability that the chord is longer than a side of an equilateral triangle inscribed in the circle? The event has these characterizations: (1) the apex angle of an isosceles triangle inscribed in the circle and having the chord as a leg is less than 60°, (2) the chord intersects the diameter perpendicular to it less than ½ a radius from the circle's center, and (3) the chord's midpoint lies within a circle concentric with the original and of ¼ its area. The definition thus suggests that the event's probability is ⅓, ½, and also ¼. Joseph Bertrand, a French mathematician, published the paradox in *Calcul des probabilités* (1889). **See also** PROBABILITY. P.We.

Beth's definability theorem, a theorem for first-order logic. A theory defines a term τ implicitly if and only if an explicit definition of the term, on the basis of the other primitive concepts, is entailed by the theory. A theory defines a term implicitly if any two models of the theory with the same domain and the same extension for the other primitive terms are identical, i.e. also have the same extension for the term. An explicit definition of a term is a sentence that states necessary and sufficient conditions for the term's applicability. Beth's theorem was implicit in a method to show independence of a term that was first used by the Italian logician Alessandro Padoa (1868–1937). Padoa suggested, in 1900, that independence of a primitive algebraic term from the other terms occurring in a set of axioms can be established by two true interpretations of the axioms that differ only in the interpretation of the term whose independence has to be proved. He claimed, without proof, that the existence of two such models is not only sufficient for, but also implied by, independence.

Tarski first gave a proof of Beth's theorem in 1926 for the logic of the *Principia Mathematica* of Whitehead and Russell, but the result was obtained for first-order logic only in 1953 by the Dutch logician Evert Beth (1908–64). In modern expositions Beth's theorem is a direct implication of Craig's interpolation theorem. In a variation on Padoa's method, Karel de Bouvère described in 1959 a one-model method to show indefinability: if the set of logical consequences of a theory formulated in terms of the remaining vocabulary cannot be extended to a model of the full theory, a term is not explicitly definable in terms of the remaining vocabulary. In the philosophy of science literature this is called a failure of Ramsey-eliminability of the term.

Bhagavad Gita (from Sanskrit *Bhagavadgītā*, "Song of the Blessed One/Exalted Lord"), Hindu devotional poem composed and edited between the fifth century B.C. and the second century A.D. It contains eighteen chapters and seven hundred verses, and forms the sixth book (Chapters 23–40) of the Indian epic Mahabharata. In its narrative, the warrior Arjuna, reluctantly waiting to wage war, receives a revelation from the Lord Krishna that emphasizes selfless deeds and *bhakti*, or devotion. Strictly classified as *smriti*, or fallible tradition, the Gita is typically treated as *shruti*, or infallible revelation. Such major thinkers as Shankara, Rāmānuja, and Madhva wrote commentaries on this beloved book. Shankara reads it as teaching that enlightenment comes through right (Advaita Vedanta) knowledge alone, even without performance of religious duties. Rāmānuja takes it to hold that enlightenment comes through performance of religious duties, particularly devotion to God for whose sake alone all other duties must be performed if one's sins are to be washed away. Such devotion leads to (or at its zenith includes) self-knowledge and knowledge of personal Brahman. Madhva sees the Gita as emphasizing divine uniqueness and the necessity of love and attachment to God and not to oneself or the consequences of one's deeds. K.E.Y.

bhakti (Sanskrit), in Hindu theistic thought systems, devotion. *Bhakti* includes the ideas of faith, surrender, love, affection, and attachment. Its most common form of expression is worship by means of offerings, *pūjā*. Theistic thinkers such as Rāmānuja and Madhva argue that devotion is the key element that solves the human predicament. As a result the deity responds with grace or kindness (*prasādam*) and thereby causes the devotee to prosper or attain *moksha*. The *Bhakti Sutras* (twelfth century A.D.) distinguish "lower *bhakti*," i.e. devotion with personal goals in mind, from "higher *bhakti*," i.e. selfless devotion practiced only to please the deity. The latter is liberation. Modern Hindu philosophers, following Shankara and the modern Hindu apologist Swami Vivekānanda (1862–1902), often relegate *bhakti* to a lower path than knowledge (*jnāna*) for those who are unable to follow philosophy, but in the philosophical systems of many theists it is defended as the highest path, with the main obstacle as unbelief, not ignorance. **See also** HINDUISM. R.N.Mi.

bhavanga, a subliminal mode of consciousness, according to Theravada Buddhist philosophers, in which no mental activity occurs. The continued existence of the *bhavanga-mind* in states where there is no intentional mental activity (e.g., dreamless sleep) is what guarantees the continuance of a particular mental continuum in such states. It operates also in ordinary events of sensation and conceptualization, being connected with such intentional mental events in complex ways, and is appealed to as an explanatory category in the accounts of the process leading from death to rebirth. Some Buddhists also use it as a soteriological category, identifying the *bhavanga-mind* with mind in its pure state, mind as luminous and radiant. **See also** ĀLAYA-VIJÑĀNA, NIRODHA-SAMĀPATTI. P.J.G.

bi **(*pi*)** (Chinese, 'screen', 'shelter', or 'cover'), Xunzi's metaphor for an obscuration or blindness of mind. In this condition the mind is obstructed in its proper functioning, e.g. thinking, remembering, imagining, and judging. In short, a *bi* is anything that obstructs the mind's cognitive task. When the mind is in the state of *bi*, reason is, so to speak, not operating properly. The opposite of *bi* is clarity of mind, a precondition for the pursuit of knowledge. A.S.C.

bian **(*pien*),** Chinese Mohist technical term for disputation, defined as 'contending over converse claims'. It involves discrimination between what does and does not "fit the facts." In Xunzi, *bian* as discrimination pertains especially to the ability to distinguish mental states (such as anger, grief, love, hate, and desires) as well as proper objects of different senses. *Bian* is significantly used in the context of justification as a phase in ethical argumentation. Among other things, *bian* as justification pertains to projection of the significance of comparable past ethical experiences to present "hard cases" of human life. A.S.C.

biconditional, the logical operator, usually written with a triple-bar sign (≡) or a double-headed arrow (↔), used to indicate that two propositions have the same truth-value: that either both are true or else both are false. The term also designates a proposition having this sign, or a natural language expression of it, as its main connective; e.g., *P* if and only if *Q*. The truth table for the biconditional is

P	Q	P-biconditional-Q
T	T	T
T	F	F
F	T	F
F	F	T

The biconditional is so called because its application is logically equivalent to the conjunction '(*P*-conditional-*Q*)-and-(*Q*-conditional-*P*)'. **See also** TRUTH TABLE. R.W.B.

bioethics, the subfield of ethics that concerns the ethical issues arising in medicine and from advances in biological science. One central area of bioethics is the ethical issues that arise in relations between health care professionals and patients. A second area focuses on broader issues of social justice in health care. A third area concerns the ethical issues raised by new biological knowledge or technology.

In relations between health care professionals and patients, a fundamental issue is the appropriate role of each in decision making about patient care. More traditional views assigning principal decision-making authority to physicians have largely been replaced with ideals of shared decision making that assign a more active role to patients. Shared decision making is thought to reflect better the importance of patients' self-determination in controlling their care. This increased role for patients is reflected in the ethical and legal doctrine of informed consent, which requires that health care not be rendered without the informed and voluntary consent of a competent patient. The requirement that consent be informed places a positive responsibility on health care professionals to provide their patients with the information they need to make informed decisions about care. The requirement that consent be voluntary requires that treatment not be forced, nor that patients' decisions be coerced or manipulated. If patients lack the capacity to make competent health care decisions, e.g. young children or cognitively impaired adults, a surrogate, typically a parent in the case of children or a close family member in the case of adults, must decide for them. Surrogates' decisions should follow the patient's advance directive if one exists, be the decision the patient would have made in the circumstances if competent, or follow the patient's best interests if the patient has never been competent or the patient's wishes are not known.

A major focus in bioethics generally, and treatment decision making in particular, is care at or near the end of life. It is now widely agreed that patients are entitled to decide about and to refuse, according to their own values, any life-sustaining treatment. They are also entitled to have desired treatments that may shorten their lives, such as high doses of pain medications necessary to relieve severe pain from cancer, although in practice pain treatment remains inadequate for many patients. Much more controversial is whether more active means to end life such as physician-assisted suicide and voluntary euthanasia are morally permissible in individual cases or justified as public policy; both remain illegal except in a very few jurisdictions.

Several other moral principles have been central to defining professional-patient relationships in health care. A principle of truth telling requires that professionals not lie to patients. Whereas in the past it was common, especially with patients with terminal cancers, not to inform patients fully about their diagnosis and prognosis, studies have shown that practice has changed substantially and that fully informing patients does not have the bad effects on patients that had been feared in the past. Principles of privacy and confidentiality require that information gathered in the professional-patient relationship not be disclosed to third parties without patients' consent. Especially with highly personal information in mental health care, or information that may lead to discrimination, such as a diagnosis of AIDS, assurance of confidentiality is fundamental to the trust necessary to a well-functioning professional-patient relationship. Nevertheless, exceptions to confidentiality to prevent imminent and serious harm to others are well recognized ethically and legally.

More recently, work in bioethics has focused on justice in the allocation of health care. Whereas nearly all developed countries treat health care as a moral and legal right, and ensure it to all their citizens through some form of national health care system, in the United States about 15 percent of the population remains without any form of health insurance. This has fed debates about whether health care is a right or privilege, a public or individual responsibility. Most bioethicists have supported a right to health care because of health care's fundamental impact on people's well-being, opportunity, ability to plan their lives, and even lives themselves. Even if there is a moral right to health care, however, few defend an unlimited right to all beneficial health care, no matter how small the benefit and how high the cost. Consequently, it is necessary to prioritize or ration health care services to reflect limited budgets for health care, and both the standards and procedures for doing so are ethically controversial. Utilitarians and defenders of cost-effectiveness analysis in health policy support using limited resources to maximize aggregate health benefits for the population. Their critics argue that this ignores concerns about equity, concerns about how health care is distributed. For example, some have argued that equity requires giving priority to treating the worst-off or sickest, even at a sacrifice in aggregate health benefits; moreover, taking account, in prioritization, of differences in costs of different treatments can lead to ethically problematic results, such as giving higher priority to providing very small benefits to many persons than to providing very large but individually more expensive benefits, including lifesaving interventions, to a few persons, as the state of Oregon found in its initial widely publicized prioritization program. In the face of controversy over standards for rationing care, it is natural to rely on fair procedures to make rationing decisions.

Other bioethics issues arise from dramatic advances in biological knowledge and technology. Perhaps the most prominent example is new knowledge of human genetics, propelled in substantial part by the worldwide Human Genome Project, which seeks to map the entire human genome. This project and related research will enable the prevention of genetically transmitted diseases, but already raises questions about which conditions should be prevented in offspring and which should be accepted and lived with, particularly when the means of preventing the condition is abortion of the fetus.

Looking further into the future, new genetic knowledge and technology will likely enable us to enhance normal capacities, not just prevent or cure disease, and to manipulate the genes of future children, raising profoundly difficult questions about what kinds of persons to create and the degree to which deliberate human design should replace "nature" in the creation of our offspring. A dramatic example of new abilities to create offspring, though now limited to the animal realm, was the cloning in Scotland in 1997 of a sheep from a single cell of an adult sheep; this event raised the very controversial prospect of cloning human beings. Finally, new reproductive technologies, such as oocyte (egg) donation, and practices such as surrogate motherhood raise deep issues about the meaning and nature of parenthood and families.

bit (from *bi*nary digi*t*), a unit or measure of information. Suggested by John W. Tukey, a bit is both an amount of information (a reduction of eight equally likely possibilities to one generates three bits [= $\log_2 8$] of information) and a system of representing that quantity. The binary system uses 1's and 0's. **See also** INFORMATION THEORY. F.A.

bivalence, principle of. See PRINCIPLE OF BIVALENCE.

black box, a hypothetical unit specified only by functional role, in order to explain some effect or behavior. The term may refer to a single entity with an unknown structure, or unknown internal organization, which realizes some known function, or to any one of a system of such entities, whose organization and functions are inferred from the behavior of an organism or entity of which they are constituents. Within behaviorism and classical learning theory, the basic functions were taken to be generalized mechanisms governing the relationship of stimulus to response, including reinforcement, inhibition, extinction, and arousal. The organism was treated as a black box realizing these functions. Within cybernetics, though there are no simple input-output rules describing the organism, there is an emphasis on functional organization and feedback in controlling behavior. The components within a cybernetic system are treated as black boxes. In both cases, the details of underlying structure, mechanism, and dynamics are either unknown or regarded as unimportant. **See also** BEHAVIORISM, PHILOSOPHY OF MIND, THEORETICAL TERM. R.C.R.

Blackburn, Simon (b.1944), British philosopher specializing in metaethics, philosophy of language, and philosophy of mind and best known for the development of expressivism in metaethics and for quasi-realism, the philosophical program that seeks to explain and justify the realistic surface features of our language in various domains (such as language about ethics, causation, and modality) in a way that is compatible with expressivism. These ideas are first fully expressed in *Spreading the Word: Groundings in the Philosophy of Language* (1984), which argues that normative judgments are best viewed as expressing attitudes rather than reporting facts about them or the world. This theory, expressivism (which Blackburn earlier called "projectivism"), takes inspiration from the early emotivists, but the attitudes expressed have more complex structure than in Ayer's version of the theory. This structure is a crucial part of the quasi-realist program. To illustrate, consider that one realist feature of moral language is that moral claims can figure in embedded contexts such as logical syllogisms: 'If lying is wrong, then getting your little brother to lie is wrong. Lying is wrong. Therefore, getting your little brother to lie is wrong.' This seems a valid inference, but if moral claims are mere expressions of attitudes without truth-values, there is no way to understand the logical connections between the three claims. Blackburn offered several widely discussed attempts to grapple with this problem, which can be seen in his collection *Essays in Quasi-Realism* (1993). Quasi-realism also makes sense of the apparent truth-aptness of moral claims by appealing to a minimalist theory of truth. In *Ruling Passions: A Theory of Practical Reasoning* (2000) he further explores the implications of expressivism and quasi-realism for our moral practice; his particular aim is to show that the authority of morality is not undermined by a sentimentalist metaethics. He is also known for his efforts to popularize philosophy. He has written a number of engaging books for general audiences, including *Think* (1999), *Being Good* (2001), and *Lust* (2004). **See also** **EMOTIVISM, ETHICS, FREGE-GEACH PROBLEM, MORAL REALISM, TRUTH.** V.T.

bleen. See GRUE PARADOX.

blindsight, a residual visual capacity resulting from lesions in certain areas of the brain (the striate cortex, area 17). Under routine clinical testing, persons suffering such lesions appear to be densely blind in particular regions of the visual field. Researchers have long recognized that, in primates, comparable lesions do not result in similar deficits. It has seemed unlikely that this disparity could be due to differences in brain function, however. And, indeed, when human subjects are tested in the way non-human subjects are tested, the disparity vanishes. Although subjects report that they can detect nothing in the blind field, when required to "guess" at properties of items situated there, they perform remarkably well. They seem to "know" the contents of the blind field while remaining unaware that they know, often expressing astonishment on being told the results of testing in the blind field. **See also** PERCEPTION. J.F.H.

Bloch, Ernst (1885–1977), German philosopher. Influenced by Marxism, his views went beyond Marxism as he matured. He fled Germany in the 1930s, but returned after World War II to a professorship in East Germany, where his increasingly unorthodox ideas were eventually censored by the Communist authorities, forcing a move to West Germany in the 1960s. His major work, *The Principle of Hope* (1954–59), is influenced by German idealism, Jewish mysticism, Neoplatonism, utopianism, and numerous other sources besides Marxism. Humans are essentially unfinished, moved by a cosmic impulse, "hope," a tendency in them to strive for the as-yet-unrealized, which manifests itself as utopia, or vision of future possibilities. Despite his atheism, Bloch wished to retrieve the sense of self-transcending that he saw in the religious and mythical traditions of humankind. His ideas have consequently influenced theology as well as philosophy, e.g. the "theology of hope" of Jürgen Moltmann. R.H.K.

Blondel, Maurice (1861–1949), French Christian philosopher who discovered the deist background of human action. In his main work, *Action* (1893, 2d ed. 1950), Blondel held that action is part of the very nature of human beings and as such becomes an object of philosophy; through philosophy, action should find its meaning, i.e. realize itself rationally. An appropriate phenomenology of action through phenomenological description uncovers the phenomenal level of action but points beyond it. Such a supra-phenomenal sense of action provides it a metaphysical status. This phenomenology of action rests on an immanent dialectics of action: a gap between the aim of the action and its realization. This gap, while dissatisfying to the actor, also drives him toward new activities. The only immanent solution of this dialectics and its consequences is a transcendent one. We have to realize that we, like other humans, cannot grasp our own activities and must accept our limitations and our finitude as well as the insufficiency of our philosophy, which is now understood as a philosophy of insufficiency and points toward the existence of the supernatural element in every human act, namely God. Human activity is the outcome of divine grace. Through action one touches the existence of God, something not possible by logical argumentation.

In the later phase of his development Blondel deserted his early "anti-intellectualism" and stressed the close relation between thought and action, now understood as inseparable and mutually interrelated. He came to see philosophy as a rational instrument of understanding one's actions as well as one's insufficiency. G.Fl.

bodily continuity. See PERSONAL IDENTITY.

Bodin, Jean (c.1529–96), French political philosopher whose philosophy centers on the concept of sovereignty. His *Six livres de la république* (1577) defines a state as constituted by common public interests, families, and the sovereign. The sovereign is the lawgiver, who stands beyond the absolute rights he possesses; he must, however, follow the law of God, natural law, and the constitution. The ideal state was for Bodin a monarchy that uses aristocratic and democratic structures of government for the sake of the common good. In order to achieve a broader empirical picture of politics Bodin used historical comparisons. This is methodologically reflected in his *Methodus ad Facilem Historiarum Cognitionem* (1566).

Bodin was clearly a theorist of absolutism. As a member of the *Politique* group he played a practical role in emancipating the state from the church. His thinking was influenced by his experience of civil war. In his *Heptaplomeres* (posthumous) he pleaded for tolerance with respect to all religions, including Islam and Judaism. As a public prosecutor, however, he wrote a manual for judges in witchcraft trials (*De la démonomanie des sorciers*, 1580). By stressing the peacemaking role of a strong state Bodin was a forerunner of Hobbes.

Boehme, Jakob (1575–1624), German Protestant speculative mystic. Influenced especially by Paracelsus, Boehme received little formal education, but was successful enough as a shoemaker to devote himself to his writing, explicating his religious experiences. He published little in his lifetime, though enough to attract charges of heresy from local clergy. He did gather followers, and his works were published after his death. His writings are elaborately symbolic rather than argumentative, but respond deeply to fundamental problems in the Christian worldview. He holds that the Godhead, omnipotent will, is as nothing to us, since we can in no way grasp it. The *Mysterium Magnum*, the ideal world, is conceived in God's mind through an impulse to self-revelation. The actual world, separate from God, is created through his will, and seeks to return to the peace of the Godhead. The world is good, as God is, but its goodness falls away, and is restored at the end of history, though not entirely, for some souls are damned eternally. Human beings enjoy free will, and create themselves through rebirth in faith. The Fall is necessary for the self-knowledge gained in recovery from it. Recognition of one's hidden, free self is a recognition of God manifested in the world, so that human salvation completes God's act of self-revelation. It is also a recognition of evil rooted in the blind will underlying all individual existence, without which there would be nothing except the Godhead. Boehme's works influenced Hegel and the later Schelling. **See also** MYSTICISM, PARACELSUS. J.LO.

Boethius, Anicius Manlius Severinus (c.480–525), Roman philosopher and Aristotelian translator and commentator. He was born into a wealthy patrician family in Rome and had a distinguished political career under the Ostrogothic king Theodoric before being arrested and executed on charges of treason. His logic and philosophical theology contain important contributions to the philosophy of the late classical and early medieval periods, and his translations of and commentaries on Aristotle profoundly influenced the history of philosophy, particularly in the medieval Latin West.

His most famous work, *The Consolation of Philosophy*, composed during his imprisonment, is a moving reflection on the nature of human happiness and the problem of evil and contains classic discussions of providence, fate, chance, and the apparent incompatibility of divine foreknowledge and human free choice. He was known during his own lifetime, however, as a brilliant scholar whose knowledge of the Greek language and ancient Greek philosophy set him apart from his Latin contemporaries. He conceived his scholarly career as devoted to preserving and making accessible to the Latin West the great philosophical achievement of ancient Greece. To this end he announced an ambitious plan to translate into Latin and write commentaries on all of Plato and Aristotle, but it seems that he achieved this goal only for Aristotle's *Organon*. His extant translations include Porphyry's *Isagoge* (an introduction to Aristotle's *Categories*) and Aristotle's *Categories, On Interpretation, Prior Analytics, Topics*, and *Sophistical Refutations*. He wrote two commentaries on the *Isagoge* and *On Interpretation* and one on the *Categories*, and we have what appear to be his notes for a commentary on the *Prior Analytics*. His translation of the *Posterior Analytics* and his commentary on the *Topics* are lost. He also commented on Cicero's *Topica* and wrote his own treatises on logic, including *De syllogismis hypotheticis, De syllogismis* *categoricis, Introductio in categoricos syllogismos, De divisione*, and *De topicis differentiis*, in which he elaborates and supplements Aristotelian logic.

Boethius shared the common Neoplatonist view that the Platonist and Aristotelian systems could be harmonized by following Aristotle in logic and natural philosophy and Plato in metaphysics and theology. This plan for harmonization rests on a distinction between two kinds of forms: (1) forms that are conjoined with matter to constitute bodies – these, which he calls "images" (*imagines*), correspond to the forms in Aristotle's hylomorphic account of corporeal substances; and (2) forms that are pure and entirely separate from matter, corresponding to Plato's ontologically separate Forms. He calls these "true forms" and "the forms themselves." He holds that the former, "enmattered" forms depend for their being on the latter, pure forms. Boethius takes these three sorts of entities – bodies, enmattered forms, and separate forms – to be the respective objects of three different cognitive activities, which constitute the three branches of speculative philosophy. Natural philosophy is concerned with enmattered forms as enmattered, mathematics with enmattered forms considered apart from their matter (though they cannot be separated from matter in actuality), and theology with the pure and separate forms. He thinks that the mental abstraction characteristic of mathematics is important for understanding the Peripatetic account of universals: the enmattered, particular forms found in sensible things can be considered as universal when they are considered apart from the matter in which they inhere (though they cannot actually exist apart from matter). But he stops short of endorsing this moderately realist Aristotelian account of universals. His commitment to an ontology that includes not just Aristotelian natural forms but also Platonist Forms existing apart from matter implies a strong realist view of universals.

With the exception of *De fide catholica*, which is a straightforward credal statement, Boethius's theological treatises (*De Trinitate, Utrum Pater et Filius, Quomodo substantiae*, and *Contra Euthychen et Nestorium*) show his commitment to using logic and metaphysics, particularly the Aristotelian doctrines of the categories and predicables, to clarify and resolve issues in Christian theology. *De Trinitate*, e.g., includes a historically influential discussion of the Aristotelian categories and the applicability of various kinds of predicates to God. Running through these treatises is his view that predicates in the category of relation are unique by virtue of not always requiring for their applicability an ontological ground in the subjects to which they apply, a doctrine that gave rise to the common medieval distinction between so-called real and non-real relations.

Regardless of the intrinsic significance of Boethius's philosophical ideas, he stands as a monumental figure in the history of medieval philosophy rivaled in importance only by Aristotle and Augustine. Until the recovery of the works of Aristotle in the mid-twelfth century, medieval philosophers depended almost entirely on Boethius's translations and commentaries for their knowledge of pagan ancient philosophy, and his treatises on logic continued to be influential throughout the Middle Ages. The preoccupation of early medieval philosophers with logic and with the problem of universals in particular is due largely to their having been tutored by Boethius and Boethius's Aristotle. The theological treatises also received wide attention in the Middle Ages, giving rise to a commentary tradition extending from the ninth century through the Renaissance and shaping discussion of central theological doctrines such as the Trinity and Incarnation.

Boltzmann, Ludwig (1844–1906), Austrian physicist who was a spirited advocate of the atomic theory and a pioneer in developing the kinetic theory of gases and statistical mechanics. Boltzmann's most famous achievements were the transport equation, the H-theorem, and the probabilistic interpretation of entropy. This work is summarized in his *Vorlesungen über Gastheorie* ("Lectures on the Theory of Gases," 1896–98). He held chairs in physics at the universities of Graz, Vienna, Munich, and Leipzig before returning to Vienna as professor of theoretical physics in 1902. In 1903 he succeeded Mach at Vienna and lectured on the philosophy of science.

In the 1890s the atomic-kinetic theory was attacked by Mach and by the energeticists led by Wilhelm Ostwald. Boltzmann's counterattack can be found in his *Populäre Schriften* ("Popular Writings," 1905). Boltzmann agreed with his critics that many of his mechanical models of gas molecules could not be true but, like Maxwell, defended models as invaluable heuristic tools. Boltzmann also insisted that it was futile to try to eliminate all metaphysical pictures from theories in favor of bare equations. For Boltzmann, the goal of physics is not merely the discovery of equations but the construction of a coherent picture of reality. Boltzmann defended his H-theorem against the reversibility objection of Loschmidt and the recurrence objection of Zermelo by conceding that a spontaneous decrease in entropy was possible but extremely unlikely. Boltzmann's views that irreversibility depends on the probability of initial conditions and that entropy increase determines the direction of time are defended by Reichenbach in *The Direction of Time* (1956).

Bolzano, Bernard (1781–1848), Austrian philosopher. He studied philosophy, mathematics, physics, and theology in Prague; received the Ph.D.; was ordained a priest (1805); was appointed to a chair in religion at Charles University in 1806; and, owing to his criticism of the Austrian constitution, was dismissed in 1819. He composed his two main works from 1823 through 1841: the *Wissenschaftslehre* (4 vols., 1837) and the posthumous *Grössenlehre*. His ontology and logical semantics influenced Husserl and, indirectly, Łukasiewicz, Tarski, and others of the Warsaw School. His conception of ethics and social philosophy affected both the cultural life of Bohemia and the Austrian system of education.

Bolzano recognized a profound distinction between the actual thoughts and judgments (*Urteile*) of human beings, their linguistic expressions, and the abstract propositions (*Sätze an sich*) and their parts which exist independently of those thoughts, judgments, and expressions. A proposition in Bolzano's sense is a preexistent sequence of ideas-as-such (*Vorstellungen an sich*). Only propositions containing finite ideas-as-such are accessible to the mind. Real things existing concretely in space and time have subsistence (*Dasein*), whereas abstract objects such as propositions have only logical existence. Adherences, i.e. forces, applied to certain concrete substances give rise to subjective ideas, thoughts, or judgments. A subjective idea is a part of a judgment that is not itself a judgment. The set of judgments is ordered by a causal relation.

Bolzano's abstract world is constituted of sets, ideas-as-such, certain properties (*Beschaffenheiten*), and objects constructed from these. Thus, sentence shapes are a kind of ideas-as-such, and certain complexes of ideas-as-such constitute propositions. Ideas-as-such can be generated from expressions of a language by postulates for the relation of being an object of something. Analogously, properties can be generated by postulates for the relation of something being applied to an object.

Bolzano's notion of religion is based on his distinction between propositions and judgments. His *Lehrbuch der Religionswissenschaft* (4 vols., 1834) distinguishes between religion in the objective and subjective senses. The former is a set of religious propositions, whereas the latter is the set of religious views of a single person. Hence, a subjective religion can contain an objective one. By defining a religious proposition as being moral and imperatives the rules of utilitarianism, Bolzano integrated his notion of religion within his ontology.

In the *Grössenlehre* Bolzano intended to give a detailed, well-founded exposition of contemporary mathematics and also to inaugurate new domains of research. Natural numbers are defined, half a century before Frege, as properties of "bijective" sets (the members of which can be put in one-to-one correspondence), and real numbers are conceived as properties of sets of certain infinite sequences of rational numbers. The analysis of infinite sets brought him to reject the Euclidean doctrine that the whole is always greater than any of its parts and, hence, to the insight that a set is infinite if and only if it is bijective to a proper subset of itself. This anticipates Peirce and Dedekind. Bolzano's extension of the linear continuum of finite numbers by infinitesimals implies a relatively constructive approach to nonstandard analysis. In the development of standard analysis the most remarkable result of the *Grössenlehre* is the anticipation of Weirstrass's discovery that there exist nowhere differentiable continuous functions.

The *Wissenschaftslehre* was intended to lay the logical and epistemological foundations of Bolzano's mathematics. A theory of science in Bolzano's sense is a collection of rules for delimiting the set of scientific textbooks. Whether a class of true propositions is a worthwhile object of representation in a scientific textbook is an ethical question decidable on utilitarian principles.

Bolzano proceeded from an expanded and standardized ordinary language through which he could describe propositions and their parts. He defined the semantic notion of truth and introduced the function corresponding to a "replacement" operation on propositions. One of his major achievements was his definition of logical derivability (*logische Ableitbarkeit*) between sets of propositions: B is logically derivable from A if and only if all elements of the sum of A and B are simultaneously true for some replacement of their non-logical ideas-as-such and if all elements of *B* are true for any such replacement that makes all elements of *A* true. In addition to this notion, which is similar to Tarski's concept of consequence of 1936, Bolzano introduced a notion corresponding to Gentzen's concept of consequence. A proposition is universally valid (*allgemeingültig*) if it is derivable from the null class. In his proof theory Bolzano formulated counterparts to Gentzen's cut rule.

Bolzano introduced a notion of inductive probability as a generalization of derivability in a limited domain. This notion has the formal properties of conditional probability. These features and Bolzano's characterization of probability density by the technique of variation are reminiscent of Wittgenstein's inductive logic and Carnap's theory of regular confirmation functions.

The replacement of conceptual complexes in propositions would, if applied to a formalized language, correspond closely to a substitution-semantic conception of quantification. His own philosophical language was based on a kind of free logic. In essence, Bolzano characterized a substitution-semantic notion of consequence with a finite number of antecedents. His quantification over individual and general concepts amounts to the introduction of a non-elementary logic of lowest order containing a quantification theory of predicate variables but no set-theoretical principles such as choice axioms. His conception of universal validity and of the semantic superstructure of logic leads to a semantically adequate extension of the predicate-logical version of Lewis's system S5 of modal logic without paradoxes. It is also possible to simulate Bolzano's theory of probability in a substitution-semantically constructed theory of probability functions. Hence, by means of an ontologically parsimonious superstructure without possible-worlds metaphysics, Bolzano was able to delimit essentially the realms of classical logical truth and additive probability spaces.

In geometry Bolzano created a new foundation from a topological point of view. He defined the notion of an isolated point of a set in a way reminiscent of the notion of a point at which a set is well-dimensional in the sense of Urysohn and Menger. On this basis he introduced his topological notion of a continuum and formulated a recursive definition of the dimensionality of non-empty subsets of the Euclidean 3-space, which is closely related to the inductive dimension concept of Urysohn and Menger. In a remarkable paragraph of an unfinished late manuscript on geometry he stated the celebrated curve theorem of Jordan.

Bonaventure, Saint (c.1221–74), Italian theologian. Born John of Fidanza in Bagnorea, Tuscany, he was educated at Paris, earning a master's degree in arts and a doctorate in theology. He joined the Franciscans about 1243, while still a student, and was elected minister general of the order in 1257. Made cardinal bishop of Albano by Pope Gregory X in 1274, Bonaventure helped organize the Second Ecumenical Council of Lyons, during the course of which he died, in July 1274. He was canonized in 1482 and named a doctor of the church in 1587.

Bonaventure wrote and preached extensively on the relation between philosophy and theology, the role of reason in spiritual and religious life, and the extent to which knowledge in God is obtainable by the "wayfarer." His basic position is nicely expressed in *De reductione artium ad theologiam* ("On the Reduction of the Arts to Theology"): "the manifold wisdom of God, which is clearly revealed in sacred scripture, lies hidden in all knowledge and in all nature." He adds, "all divisions of knowledge are handmaids of theology." But he is critical of those theologians who wish to sever the connection between faith and reason. As he argues in another famous work, *Itinerarium mentis ad deum* ("The Mind's Journey unto God," 1259), "since, relative to our life on earth, the world is itself a ladder for ascending to God, we find here certain traces, certain images" of the divine hand, in which God himself is mirrored.

Although Bonaventure's own philosophical outlook is Augustinian, he was also influenced by Aristotle, whose newly available works he both read and appreciated. Thus, while upholding the Aristotelian ideas that knowledge of the external world is based on the senses and that the mind comes into existence as a *tabula rasa*, he also contends that divine illumination is necessary to explain both the acquisition of universal concepts from sense images and the certainty of intellectual judgment. His own illuminationist epistemology seeks a middle ground between, on the one hand, those who maintain that the eternal light is the sole reason for human knowing, providing the human intellect with its archetypal and intelligible objects, and, on the other, those holding that the eternal light merely influences human knowing, helping guide it toward truth. He holds that our intellect has certain knowledge when stable; eternal archetypes are "contuited by us [*a nobis contuita*],” together with intelligible species produced by its own fallible powers.

In metaphysics, Bonaventure defends exemplarism, the doctrine that all creation is patterned after exemplar causes or ideas in the mind of God. Like Aquinas, but unlike Duns Scotus, he argues that it is through such ideas that God knows all creatures. He also adopts the emanationist principle that creation proceeds from God’s goodness, which is self-diffusive, but differs from other emanationists, such as al-Fārābī, Avicenna, and Averroes, in arguing that divine emanation is neither necessary nor indirect (i.e., accomplished by secondary agents or intelligences). Indeed, he sees the views of these Islamic philosophers as typical of the errors bound to follow once Aristotelian rationalism is taken to its extreme. He is also well known for his anti-Aristotelian argument that the eternity of the world – something even Aquinas (following Maimonides) concedes as a theoretical possibility – is demonstrably false.

Bonaventure also subscribes to several other doctrines characteristic of medieval Augustinianism: universal hylomorphism, the thesis, defended by Ibn Gabirol and Avicenna (among others), that everything other than God is composed of matter and form; the plurality of forms, the view that subjects and predicates in the category of substance are ordered in terms of their metaphysical priority; and the ontological view of truth, according to which truth is a kind of rightness perceived by the mind. In a similar vein, Bonaventure argues that knowledge ultimately consists in perceiving truth directly, without argument or demonstration.

Bonaventure also wrote several classic works in the tradition of mystical theology. His best-known and most popular mystical work is the aforementioned *Itinerarium*, written in 1259 on a pilgrimage to La Verna, during which he beheld the six-winged seraph that had also appeared to Francis of Assisi when Francis received the stigmata. Bonaventure outlines a seven-stage spiritual journey, in which our mind moves from first considering God’s traces in the perfections of irrational creatures, to a final state of peaceful repose, in which our affections are “transferred and transformed into God.” Central to his writings on spiritual life is the theme of the “three ways”: the purgative way, inspired by conscience, which expels sin; the illuminative way, inspired by the intellect, which imitates Christ; and the unitive way, inspired by wisdom, which unites us to God through love.

Bonaventure’s writings most immediately influenced the work of other medieval Augustinians, such as Matthew of Aquasparta and John Peckham, and later, followers of Duns Scotus. But his modern reputation rests on his profound contributions to philosophical theology, Franciscan spirituality, and mystical thought, in all three of which he remains an authoritative source.

BonJour, Laurence (b.1943), American philosopher well known for his work in epistemology and especially for a clarification and widely debated defense of coherentism regarding the empirical realm (1985) and for an account of a priori justification (1998). He received his Ph.D. from Princeton University (1969) under Rorty and has spent most of his career at the University of Washington, Seattle.

BonJour’s publications are exemplars of clarity, accessibility, and depth, and have enjoyed a wide readership. He is known primarily for the following. (1) In reaction to the development of epistemological externalism in the 1960s and 1970s, he defended the internalist thesis that a belief is justified only if the believer has access to some reason supporting its truth. Central to his critique were counterexamples aimed to show that externalist conditions (including reliable belief-production) are not sufficient for justified belief. (2) At around the same time, BonJour argued against foundationalism regarding empirical justification, claiming that only something judgmental or belief-like can justify a belief. He developed a coherentist account on which justification for any empirical belief depends on its coherence with the rest of one’s beliefs. His influential first book, *The Structure of Empirical Knowledge* (1985), sharpened these critiques and developed and defended his coherentist alternative. (3) BonJour endorsed foundationalism regarding *a priori* justification even while defending coherentism regarding *empirical* justification. His second book, *In Defense of Pure Reason* (1998), argued against empiricism (and naturalistic epistemology) and for a version of rationalism for which rational insight into necessities provides a defeasible source of a priori justification. (4) In the late 1990s and early 2000s, he surprised many by embracing a traditional version of empirical foundationalism. He responded to objections against the possibility of such foundations (including his own) and argued that such a view can defeat skepticism regarding the external world. A.H.

boo-hurrah theory. See EMOTIVISM.

Book of Changes. See I-CHING.

book of life, expression found in Hebrew and Christian scriptures signifying a record kept by the Lord of those destined for eternal happiness (Exodus 32:32; Psalms 68; Malachi 3:16; Daniel 12:1; Philippians 4:3; Revelation 3:5, 17:8, 20:12, 21:27). Medieval philosophers often referred to the book of life when discussing issues of predestination, divine omniscience, foreknowledge, and free will. Figures like Augustine and Aquinas asked whether it represented God's unerring foreknowledge or predestination, or whether some names could be added or deleted from it. The term is used by some contemporary philosophers to mean a record of all the events in a person's life. **See also** FREE WILL PROBLEM. R.H.K.

Boole, George (1815–64), English mathematician and logician, widely considered the founder of mathematical logic. Called the Galileo of logic, he established the mathematical nature of logic. He is widely viewed as among the five greatest logicians, the others being Aristotle, Frege, Gödel, and Tarski.

"On a General Method in Analysis" (1844) won the Royal Society's prize for "the most significant contribution to mathematics" in the five years 1840–44. At thirty-four, though entirely self-taught, he became professor of mathematics at Queen's University. At his death at age forty-nine, he was among the most celebrated figures on the British intellectual scene, having received honorary doctoral degrees from Trinity College, Dublin, and from Oxford University.

In his lifetime Boole was known almost exclusively for mathematical analysis, which includes traditional algebra, differential equations, calculus of finite differences, and differential and integral calculus. Today his work in mathematical analysis is largely unknown; his fame rests on his logic. Boolean algebra, the branch of mathematics named in his honor, derives from his logic. A new edition of his *Laws of Thought* (London, 1854) appeared in 2003. In 1865, his logic was the subject of Charles Sanders Peirce's Harvard lecture, "Boole's Calculus of Logic." Peirce began prophetically: "Perhaps the most extraordinary view of logic which has ever been developed is that of Boole. His *Laws of Thought* is destined to mark a great epoch in logic; it will rival Aristotle's *Organon*."

See also ARISTOTLE, AXIOMATIC METHOD, BOOLEAN ALGEBRA, CALCULUS, DE MORGAN, FORMAL LOGIC, FREGE, GÖDEL, MATHEMATICAL ANALYSIS, PEIRCE, TARSKI, UNIVERSE OF DISCOURSE. J.Cor.

Boolean algebra, (1) an ordered triple $(\mathbf{B},-,\cap)$, where $\mathbf{B}$ is a set containing at least two elements and $-$ and $\cap$ are unary and binary operations in $\mathbf{B}$ such that (i) $a \cap b = b \cap a$, (ii) $a \cap (b \cap c) = (a \cap b) \cap c$, (iii) $a \cap -a = b \cap -b$, and (iv) $a \cap b = a$ if and only if $a \cap -b = a \cap -a$; (2) the theory of such algebras. Such structures are modern descendants of algebras published by the mathematician G. Boole in 1847 and representing the first successful algebraic treatment of logic. (Interpreting $-$ and $\cap$ as negation and conjunction, respectively, makes Boolean algebra a calculus of propositions. Likewise, if $\mathbf{B} = \{T,F\}$ and $-$ and $\cap$ are the truth-functions for negation and conjunction, then $(\mathbf{B},-,\cap)$ – the truth table for those two connectives – forms a two-element Boolean algebra.) Picturing a Boolean algebra is simple. $(\mathbf{B},-,\cap)$ is a *full subset algebra* if $\mathbf{B}$ is the set of all subsets of a given set and $-$ and $\cap$ are set complementation and intersection, respectively. Then every finite Boolean algebra is isomorphic to a full subset algebra, while every infinite Boolean algebra is isomorphic to a sub-algebra of such an algebra. It is for this reason that Boolean algebra is often characterized as the *calculus of classes*. **See also** SET THEORY, TRUTH TABLE. G.F.S.

bootstrapping, a defective procedure whereby the reliability of a source of belief is established by reference to that very source. The term was coined by Jonathan Vogel, who argued that reliabilism cannot find fault with evidently faulty bootstrapping maneuvers such as the following: Roxanne has a car. The gas gauge of her car is in fact reliable, though she has no justification for thinking that it is or that it is not. Roxanne now reasons as follows: (i) on this occasion the gas gauge indicates the tank is two-thirds full; (ii) on this occasion the gas tank is two-thirds full; (iii) hence, on this occasion the gas gauge is accurate. According to the reliabilist, Roxanne's belief in (i) is justified because formed by means of a reliable process, perception. Her belief in (ii) is justified because, *ex hypothesi*, the gas gauge is in fact reliable (though, of course, Roxanne does not know this). Assuming that justified belief is deductively closed, her belief in (iii) is justified because deducible from (i) and (ii). Repeating this reasoning on numerous occasions, Roxanne may inductively form the justified belief that the gas gauge is generally reliable. But this seems problematic, given the circularity of the procedure.

It has been argued that bootstrapping worries afflict not just reliabilism, but any epistemological theory that allows beliefs to be justified when they originate from a source whose reliability has not been ascertained.

In the literature on practical rationality, 'bootstrapping' also designates a problem faced by certain principles of instrumental reasoning. For instance, on one reading of the principle 'If you intend *E*, and *M* is a necessary means for *E*, then you ought to *M*', an agent can make it the case that she ought to *M* merely by intending an end for which *M* is a necessary means; e.g., if I intend to win the race and tripping my competitor is a necessary means to that end, it follows that tripping my competitor is what I ought to do.

See also CONDITIONING, EPISTEMOLOGY, INSTRUMENTAL RATIONALITY, RATIONALITY, RELIABILISM. F.L.

borderline case, in the logical sense, a case that falls within the "gray area" or "twilight zone" associated with a vague concept; in the pragmatic sense, a doubtful, disputed, or arguable case. These two senses are not mutually exclusive, of course. A moment of time near sunrise or sunset may be a borderline case of daytime or nighttime in the logical sense, but not in the pragmatic sense. A sufficiently freshly fertilized ovum may be a borderline case of a person in both senses. Goldbach's conjecture, or any of a large number of other disputed mathematical propositions, may be a borderline case in the pragmatic sense but not in the logical sense. A borderline case per se in either sense need not be a limiting case or a degenerate case. **See also** DEGENERATE CASE, LIMITING CASE, VAGUENESS. J.Cor.

Born interpretation. See QUANTUM MECHANICS.

Bosanquet, Bernard (1848–1923), British philosopher, the most systematic British absolute idealist, and, with F. H. Bradley, the leading British defender of absolute idealism. Although he derived his name from Huguenot ancestors, Bosanquet was thoroughly English. Born at Altwick and educated at Harrow and Balliol College, Oxford, he was for eleven years a fellow of University College, Oxford. The death of his father in 1880 and the resulting inheritance enabled Bosanquet to leave Oxford for London and a career as a writer and social activist. While writing, he taught courses for the London Ethical Society's Center for University Extension and donated time to the Charity Organization Society. In 1895 he married his co-worker in the Charity Organization Society, Helen Dendy, who was also the translator of Christoph Sigwart's *Logic*. Bosanquet was professor of moral philosophy at St. Andrews from 1903 to 1908. He gave the Gifford Lectures in 1911 and 1912. Otherwise he lived in London until his death.

Bosanquet's most comprehensive work, his two-volume Gifford Lectures, *The Principle of Individuality and Value* and *The Value and Destiny of the Individual*, covers most aspects of his philosophy. In *The Principle of Individuality and Value* he argues that the search for truth proceeds by eliminating contradictions in experience. (For Bosanquet a contradiction arises when there are incompatible interpretations of the same fact.) This involves making distinctions that harmonize the incompatible interpretations in a larger body of knowledge. Bosanquet thought there was no way to arrest this process short of recognizing that all human experience forms a comprehensive whole which is reality. Bosanquet called this totality "the Absolute." Just as conflicting interpretations of the same fact find harmonious places in the Absolute, so conflicting desires are also included. The Absolute thus satisfies all desires and provides Bosanquet's standard for evaluating other objects. This is because in his view the value of an object is determined by its ability to satisfy desires. From this Bosanquet concluded that human beings, as fragments of the Absolute, acquire greater value as they realize themselves by partaking more fully in the Absolute. In *The Value and Destiny of the Individual* Bosanquet explained how human beings could do this. As finite, human beings face obstacles they cannot overcome; yet they desire the good (i.e., the Absolute) which for Bosanquet overcomes all obstacles and satisfies all desires. Humans can best realize a desire for the good, Bosanquet thinks, by surrendering their private desires for the sake of the good. This attitude of surrender, which Bosanquet calls the religious consciousness, relates human beings to what is permanently valuable in reality and increases their own value and satisfaction accordingly.

Bosanquet's defense of this metaphysical vision rests heavily on his first major work, *Logic or the Morphology of Knowledge* (1888; 2d ed. 1911). As the second part of the title indicates, Bosanquet took the subject matter of logic to be the structure of knowledge. Like Hegel, who was in many ways his inspiration, Bosanquet thought that the nature of knowledge was defined by structures repeated in different parts of knowledge. He called these structures forms of judgment and tried to show that simple judgments are dependent on increasingly complex ones and finally on an all-inclusive judgment that defines reality. For example, the simplest element of knowledge is a demonstrative judgment like 'This is hot'. But making such a judgment presupposes understanding the contrast between 'this' and 'that'. Demonstrative judgments thus depend on comparative judgments like 'This is hotter than that'. Since these judgments are less dependent on other judgments, they more fully embody human knowledge. Bosanquet claimed that the series of increasingly complex judgments are not arranged in a simple linear order but develop along different branches, finally uniting in disjunctive judgments that attribute to reality an exhaustive set of mutually exclusive alternatives which are themselves judgments. When one contained judgment is asserted on the basis of another, a judgment containing both is an *inference*. For Bosanquet inferences are mediated judgments that assert their conclusions based on grounds. When these grounds are made fully explicit in a judgment containing them, that judgment embodies the nature of inference: that one must accept the conclusion or reject the whole of knowledge. Since for Bosanquet the difference between any judgment and the reality it represents is that a judgment is composed of ideas that abstract from reality, a fully comprehensive judgment includes all aspects of reality. It is thus identical to reality. By locating all judgments within this one, Bosanquet claimed to have described the morphology of knowledge as well as to have shown that thought is identical to reality.

Bosanquet removed an objection to this identification in *History of Aesthetics* (1892), where he traces the development of the philosophy of the beautiful from its inception through absolute idealism. According to Plato and Aristotle beauty is found in imitations of reality, while in objective idealism it *is* reality in sensuous form. Drawing heavily on Kant, Bosanquet saw this process as an overcoming of the opposition between sense and reason by showing how a pleasurable feeling can partake of reason. He thought that absolute idealism explained this by showing that we experience objects as beautiful because their sensible qualities exhibit the unifying activity of reason.

Bosanquet treated the political implications of absolute idealism in his *Philosophical Theory of the State* (1898; 3d ed. 1920), where he argues that humans achieve their ends only in communities. According to Bosanquet, all humans rationally will their own ends. Because their ends differ from moment to moment, the ends they rationally will are those that harmonize their desires at particular moments. Similarly, because the ends of different individuals overlap and conflict, what they rationally will are ends that harmonize their desires, which are the ends of humans in communities. They are willed by the general will, the realization of which is self-rule or liberty. This provides the rational ground of political obligation, since the most comprehensive system of modern life is the state, the end of which is the realization of the best life for its citizens.

Boscovich, Roger Joseph, or Rudjer Josip Bošković (1711–87), Croatian physicist and philosopher. Born of Serbian and Italian parents, he was a Jesuit and polymath best known for his *A Theory of Natural Philosophy Reduced to a Single Law of the Actions Existing in Nature*. This work attempts to explain all physical phenomena in terms of the attractions and repulsions of point particles (*puncta*) that are indistinguishable in their intrinsic qualitative properties. According to Boscovich's single law, *puncta* at a certain distance attract, until upon approaching one another they reach a point at which they repel, and eventually reach equilibrium. Thus, Boscovich defends a form of dynamism, or the theory that nature is to be understood in terms of force and not mass (where forces are functions of time and distance). By dispensing with extended substance, Boscovich avoided epistemological difficulties facing Locke's natural philosophy and anticipated developments in modern physics. Among those influenced by Boscovich were Kant (who defended a version of dynamism), Faraday, James Clerk Maxwell, and Lord Kelvin.

Boscovich's theory has proved to be empirically inadequate to account for phenomena such as light. A philosophical difficulty for Boscovich's *puncta*, which are physical substances, arises out of their zero-dimensionality. It is plausible that any power must have a basis in an object's intrinsic properties, and *puncta* appear to lack such support for their powers. However, it is extensional properties that *puncta* lack, and Boscovich could argue that the categorial property of being an unextended spatial substance provides the needed basis. J.Ho. & G.Ro.

bound variable. See ONTOLOGICAL COMMITMENT, VARIABLE.

Bouwsma, O(ets) K(olk) (1898–1978), American philosopher, a practitioner of ordinary language philosophy and celebrated teacher. Through work on Moore and contact with students such as Norman Malcolm and Morris Lazerowitz, whom he sent from Nebraska to work with Moore, Bouwsma discovered Wittgenstein. He became known for conveying an understanding of Wittgenstein's techniques of philosophical analysis through his own often humorous grasp of sense and nonsense. Focusing on a particular pivotal sentence in an argument, he provided imaginative surroundings for it, showing how, in the philosopher's mouth, the sentence lacked sense. He sometimes described this as "the method of failure." In connection with Descartes's evil genius, e.g., Bouwsma invents an elaborate story in which the evil genius tries but fails to permanently deceive by means of a totally paper world. Our inability to imagine such a deception undermines the sense of the evil genius argument. His writings are replete with similar stories, analogies, and teases of sense and nonsense for such philosophical standards as Berkeley's idealism, Moore's theory of sense-data, and Anselm's ontological argument.

Bouwsma did not advocate theories or put forward refutations of other philosophers' views. His talent lay rather in exposing some central sentence in an argument as disguised nonsense. In this, he went beyond Wittgenstein, working out the details of the latter's insights into language. In addition to this appropriation of Wittgenstein, Bouwsma also appropriated Kierkegaard, understanding him too as one who dispelled philosophical illusions – those arising from the attempt to understand Christianity. The ordinary language of religious philosophy was that of scriptures. He drew upon this language in his many essays on religious themes. His religious dimension made whole this person who gave no quarter to traditional metaphysics. His papers are published under the titles *Philosophical Essays, Toward a New Sensibility, Without Proof or Evidence,* and *Wittgenstein Conversations, 1949–51*. His philosophical notebooks are housed at the Humanities Research Center in Austin, Texas.

See also ORDINARY LANGUAGE PHILOSOPHY, WITTGENSTEIN. R.E.H.

Boyle, Robert (1627–91), British chemist and physicist who was a major figure in seventeenth-century natural philosophy. To his contemporaries he was "the restorer" in England of the mechanical philosophy. His program was to replace the vacuous explanations characteristic of Peripateticism (the "quality of whiteness" in snow explains why it dazzles the eyes) by explanations employing the "two grand and most catholic principles of bodies, matter and motion," matter being composed of corpuscles, with motion "the grand agent of all that happens in nature." Boyle wrote influentially on scientific methodology, emphasizing experimentation (a Baconian influence), experimental precision, and the importance of devising "good and excellent" hypotheses. The dispute with Spinoza on the validation of explanatory hypotheses contrasted Boyle's experimental way with Spinoza's way of rational analysis. The 1670s dispute with Henry More on the ontological grounds of corporeal activity confronted More's "Spirit of Nature" with the "essential modifications" (motion and the "seminal principle" of activity) with which Boyle claimed God had directly endowed matter. As a champion of the corpuscularian philosophy, Boyle was an important link in the development before Locke of the distinction between primary and secondary qualities. A leading advocate of natural theology, he provided in his will for the establishment of the Boyle Lectures to defend Protestant Christianity against atheism and materialism.

Bradley, F(rancis) H(erbert) (1846–1924), the most original and influential nineteenth-century British idealist. Born in Clapham, he was the fourth son of an evangelical minister. His younger brother A. C. Bradley was a well-known Shakespearean critic. From 1870 until his death Bradley was a fellow of Merton College, Oxford. A kidney ailment compelled him to lead a retiring life. This, combined with his forceful literary style, his love of irony, the dedication of three of his books to an unknown woman, and acclaim as the greatest British idealist since Berkeley, has lent an aura of mystery to his personal life.

The aim of Bradley's first important work, *Ethical Studies* (1876), is not to offer guidance for dealing with practical moral problems (Bradley condemned this as casuistry), but rather to explain what makes morality as embodied in the consciousness of individuals and in social institutions possible. Bradley thought it was the fact that moral agents take morality as an end in itself, which involves identifying their wills with an ideal (provided in part by their stations in society) and then transferring that ideal to reality through action. Bradley called this process "self-realization." He thought that moral agents could realize their good selves only by suppressing their bad selves, from which he concluded that morality could never be completely realized, since realizing a good self requires having a bad one. For this reason Bradley believed that the moral consciousness would develop into religious consciousness which, in his secularized version of Christianity, required dying to one's natural self through faith in the actual existence of the moral ideal.

In *Ethical Studies* Bradley admitted that a full defense of his ethics would require a metaphysical system, something he did not then have. Much of Bradley's remaining work was an attempt to provide the outline of such a system by solving what he called "the great problem of the relation between thought and reality." He first confronted this problem in *The Principles of Logic* (1883), which is his description of thought. He took thought to be embodied in judgments, which are distinguished from other mental activities by being true or false. This is made possible by the fact that their contents, which Bradley called ideas, represent reality. A problem arises because ideas are universals and so represent kinds of things, while the things themselves are all individuals. Bradley solves this problem by distinguishing between the logical and grammatical forms of a judgment and arguing that all judgments have the logical form of conditionals. They assert that universal connections between qualities obtain in reality. The qualities are universals, the connections between them are conditional, while reality is one individual whole that we have contact with in immediate experience. All judgments, in his view, are abstractions from a diverse but non-relational immediate experience. Since judgments are inescapably relational, they fail to represent accurately non-relational reality and so fail to reach truth, which is the goal of thought. From this Bradley concluded that, contrary to what some of his more Hegelian contemporaries were saying, thought is not identical to reality and is never more than partially true.

Appearance and Reality (1893) is Bradley's description of reality: it is experience, all of it, all at once, blended in a harmonious way. Bradley defended this view by means of his criterion for reality. Reality, he proclaimed, does not contradict itself; anything that does is merely appearance. In Part I of *Appearance and Reality* Bradley relied on an infinite regress argument, now called *Bradley's regress*, to contend that relations and all relational phenomena, including thought, are contradictory. They are appearance, not reality. In Part II he claimed that appearances are contradictory because they are abstracted by thought from the immediate experience of which they are a part. Appearances constitute the content of this whole, which in Bradley's view is experience. In other words, reality is experience in its totality. Bradley called this unified, consistent, all-inclusive reality "the Absolute."

Today Bradley is remembered mainly for his argument against the reality of relations, and as the philosopher who provoked Russell's and Moore's revolution in philosophy. He would be better remembered as a founder of twentieth-century philosophy who based metaphysical conclusions on his account of the logical forms of judgments.

Brahma. See BRAHMAN.

Brahman, in Hinduism, the ultimate reality, possessed of being, consciousness, and bliss, dependent on nothing else for existence. Brahman is conceived as a personal deity (Brahma) in Viśistadvaita and Dvaita Vedanta and as apersonal and quality-less in Advaita Vedanta, in which being, consciousness, and bliss are interpreted negatively. While Brahman is conceived as *saguna*, or 'with qualities', in Viśistadvaita and Dvaita, for Advaita Brahman is *nirguna*, or quality-less. For Viśistadvaita, 'Brahman' secondarily refers to the world dependent on Brahman strictly so called, namely all minds and material things that constitute Brahman's body. For Advaita, each apparently individual mind (or other thing) is identical to Brahman; Dvaita does not construe the world, or anything else, as Brahman's body. Enlightenment, or *moksha*, with its consequent escape from the cycle of rebirths, for Advaita involves recognizing one's identity with *nirguna* Brahman, and for Dvaita and Viśistadvaita involves repenting and forsaking one's sins and trusting a gracious Brahman for salvation. **See also** HINDUISM. Brandom, Robert (b.1950), American philosopher renowned for his doctrine of *inferentialism*.

He took his Ph.D. at Princeton in 1977, under Rorty, and since 1976 has been professor of philosophy of the University of Pittsburgh, where he met Wilfrid Sellars, whose ideas deeply influenced him. His most important book, *Making It Explicit* (1994), a volume of more than seven hundred pages, lays out his general philosophical doctrine, on which the meaning of an expression is a matter of inferential rules governing the employment of the expression. (In this way, inferentialism is differentiated from the concurrent *representationalism*, according to which meaningfulness is a matter of representing or *standing for*.) This view is based on the assumption that language is basically a norm-governed enterprise, and indeed that living in a human society amounts to steering within a rich network of normative social relationships and enjoying many kinds of normative statuses, which reach into many dimensions. Linguistic communication institutes an important stratum of such statuses (commitments and entitlements), and to understand language means being able to keep track of the statuses of one's fellow speakers – to keep score on them, as Brandom puts it. The social distribution is essential because it provides for the multiplicity of perspectives the intersections of which make the objectivity of linguistic content possible.

In *Between Saying and Doing* (2008), Brandom elaborates his view into a position he calls *analytic pragmatism*, which aims at combining the insights of classical pragmatism with the formal rigor of analytic philosophy. Aside from these books, Brandom published *Articulating Reasons* (2001), *Tales of the Mighty Dead* (2002), *Reason in Philosophy* (2009), and *Perspectives on Pragmatism* (2011). In recent years, he has been working on a monograph about the philosophy of Hegel, whose ideas he finds congenial to his own program.

Brandt, Richard B. (1910–97), American moral philosopher, most closely associated with *rule utilitarianism* (which term he coined). Brandt earned degrees from Denison College and Cambridge University, and obtained a Ph.D. from Yale in 1936. He taught at Swarthmore College from 1937 to 1964 and at the University of Michigan from 1964 to 1981. His six books and nearly one hundred articles included work on philosophy of religion, epistemology, philosophy of mind, philosophy of action, political philosophy, and philosophy of law. His greatest contributions were in moral philosophy. He first defended rule utilitarianism in his textbook *Ethical Theory* (1959), but greatly refined his view in the 1960s in a series of articles, which were widely discussed and reprinted and eventually compiled in *Morality, Utilitarianism, and Rights* (1992). Further refinements appear in his *Theory of the Good and the Right* (1979) and *Facts, Values, and Morality* (1996).

Brandt famously argued for a "reforming definition" of 'rational person'. He proposed that we use it to designate someone whose desires would survive exposure to all relevant empirical facts and to correct logical reasoning. He also proposed a "reforming definition" of 'morally right' that assigns it the descriptive meaning 'would be permitted by any moral code that all (or nearly all) rational people would publicly favor for the agent's society if they expected to spend a lifetime in that society'. In his view, rational choice between moral codes is determined not by prior moral commitments but by expected consequences. Brandt admitted that different rational people may favor different codes, since different rational people may have different levels of natural benevolence. But he also contended that most rational people would favor a rule-utilitarian code.

Bratman, Michael (b.1945), American philosopher and Stanford University professor who has identified special roles of intention in practical reasoning, interpersonal coordination, and the cross-temporal organization of behavior – roles that he argues cannot be played by belief-desire complexes. His "planning theory of intention" is motivated by these observations.

Influenced by Herbert Simon's work in decision theory, Bratman noted that intentions have a characteristic stability that help to reduce deliberation costs. When an agent intends to act later, it becomes irrational to deliberate again later, unless the rational landscape changes significantly. Thus, in a rational agent intentions override conditions that would otherwise prompt further deliberation. Observations of this kind, concerned with the rational pressures applicable to intending agents, provide the basis for Bratman's articulation of principles of rational coherence governing those with intentions. The planning theory was offered in "Two Faces of Intention" (*Philosophical Review*, 1984) and developed in detail in *Intention, Plans and Practical Reason* (1987).

Later, in essays since collected in two volumes, Bratman extended the planning theory to account for various phenomena of individual and collective rational psychology. Self-governance, identification, and valuing can all be understood through appeal to settled intentions to treat certain considerations as reasons for action, he argued. In essays included in the collections, and in *Shared Agency* (2013), he explains the distinctive features of collective intention and action through appeal to the planning theory.

A volume of Bratman's critical essays and replies will be published by Oxford University Press. In 2008 the International Foundation of Autonomous Agents and Multi-Agent Systems gave its highest award for influence to "Plans and Resource-Bounded Practical Reasoning" (*Computational Intelligence*, 1988, co-written with David Israel and Martha Pollack), which laid the groundwork for an artificial intelligence architecture incorporating aspects of the planning theory. G.Y.

Brentano, Franz (1838–1917), German philosopher, one of the most intellectually influential and personally charismatic of his time. He is known especially for his distinction between psychological and physical phenomena on the basis of intentionality or internal object-directedness of thought, his revival of Aristotelianism and empirical methods in philosophy and psychology, and his value theory and ethics supported by the concept of correct pro- and anti-emotions or love and hate attitudes. Brentano made noted contributions to the theory of metaphysical categories, phenomenology, epistemology, syllogistic logic, and philosophy of religion. His teaching made a profound impact on his students in Würzburg and Vienna, many of whom became internationally respected thinkers in their fields, including Meinong, Husserl, Twardowski, Christian von Ehrenfels, Anton Marty, and Freud.

Brentano began his study of philosophy at the Aschaffenburg Royal Bavarian Gymnasium; in 1856–58 he attended the universities of Munich and Würzburg, and then enrolled at the University of Berlin, where he undertook his first investigations of Aristotle's metaphysics under the supervision of F. A. Trendelenburg. In 1859–60, he attended the Academy in Münster, reading intensively in the medieval Aristotelians; in 1862 he received the doctorate in philosophy *in absentia* from the University of Tübingen. He was ordained a Catholic priest in 1864, and was later involved in a controversy over the doctrine of papal infallibility, eventually leaving the church in 1873. He taught first as *Privatdozent* in the Philosophical Faculty of the University of Würzburg (1866–74), and then accepted a professorship at the University of Vienna. In 1880 he decided to marry, temporarily resigning his position to acquire Saxon citizenship, in order to avoid legal difficulties in Austria, where marriages of former priests were not officially recognized. Brentano was promised restoration of his position after his circumvention of these restrictions, but although he was later reinstated as lecturer, his appeals for reappointment as professor were answered only with delay and equivocation. He left Vienna in 1895, retiring to Italy, his family's country of origin. At last he moved to Zürich, Switzerland, shortly before Italy entered World War I. Here he remained active both in philosophy and in psychology, despite his ensuing blindness, writing and revising numerous books and articles, frequently meeting with former students and colleagues, and maintaining an extensive philosophical-literary correspondence, until his death.

In *Psychologie vom empirischen Standpunkt* ("Psychology from an Empirical Standpoint," 1874), Brentano argued that intentionality is the mark of the mental, that every psychological experience contains an intended object – also called an intentional object – which the thought is about or toward which the thought is directed. Thus, *in* desire, something is desired. According to the immanent intentionality thesis, this means that the desired object is literally contained within the psychological experience of desire. Brentano claims that this is uniquely true of mental as opposed to physical or non-psychological phenomena, so that the intentionality of the psychological distinguishes mental from physical states. The immanent intentionality thesis provides a framework in which Brentano identifies three categories of psychological phenomena: thoughts (*Vorstellungen*), judgments, and emotive phenomena. He further maintains that every thought is also self-consciously reflected back onto itself as a secondary intended object in what he called the *eigentümliche Verfleckung*.

From 1905 through 1911, with the publication in 1911 of *Von der Klassifikation der psychischen Phänomene*, Brentano gradually abandoned the immanent intentionality thesis in favor of his later philosophy of reism, according to which only individuals exist, excluding putative nonexistent *irrealia*, such as lacks, absences, and mere possibilities. In the meantime, his students Twardowski, Meinong, and Husserl, reacting negatively to the idealism, psychologism, and related philosophical problems apparent in the early immanent intentionality thesis, developed alternative non-immanence approaches to intentionality, leading, in the case of Twardowski and Meinong and his students in the Graz school of phenomenological psychology, to the construction of *Gegenstandstheorie*, the theory of (transcendent existent and nonexistent intended) objects, and to Husserl's later transcendental phenomenology. The intentionality of the mental in Brentano's revival of the medieval Aristotelian doctrine is one of his most important contributions to contemporary non-mechanistic theories of mind, meaning, and expression. Brentano's immanent intentionality thesis was, however, rejected by philosophers who otherwise agreed with his underlying claim that thought is essentially object-directed.

Brentano's value theory (*Werttheorie*) offers a pluralistic account of value, permitting many different kinds of things to be valuable – although, in keeping with his later reism, he denies the existence of an abstract realm of values. Intrinsic value is objective rather than subjective, in the sense that he believes the pro- and anti-emotions we may have toward an act or situation are objectively correct if they present themselves to emotional preference with the same *apodicity* or unquestionable sense of rightness as other self-evident matters of non-ethical judgment. Among the controversial consequences of Brentano's value theory is the conclusion that there can be no such thing as absolute evil. The implication follows from Brentano's observation, first, that evil requires evil consciousness, and that consciousness of any kind, even the worst imaginable malice or malevolent ill will, is (considered merely as consciousness) intrinsically good. This means that necessarily there is always a mixture of intrinsic good even in the most malicious possible states of mind, by virtue alone of being consciously experienced, so that pure evil never obtains. Brentano's value theory admits of no defense against those who happen not to share the same "correct" emotional attitudes toward the situations he describes. If it is objected that to another person's emotional preferences only good consciousness is intrinsically good, while infinitely bad consciousness despite being a state of consciousness appears instead to contain no intrinsic good and is absolutely evil, there is no recourse within Brentano's ethics except to acknowledge that this contrary emotive attitude toward infinitely bad consciousness may also be correct, even though it contradicts his evaluations.

Brentano's empirical psychology and articulation of the intentionality thesis, his moral philosophy and value theory, his investigations of Aristotle's metaphysics at a time when Aristotelian realism was little appreciated in the prevailing climate of post-Kantian idealism, his epistemic theory of evident judgment, his suggestions for the reform of syllogistic logic, his treatment of the principle of sufficient reason and existence of God, his interpretation of a four-stage cycle of successive trends in the history of philosophy, together with his teaching and personal moral example, continue to inspire a variety of divergent philosophical traditions.

British empiricism, the seventeenth- and eighteenth-century philosophical tradition associated chiefly with Hobbes, Boyle, Locke, Berkeley, and Hume, commonly known simply as 'the Empiricists'. With the exception of Boyle, their views on a variety of topics in metaphysics, epistemology, philosophy of mind, and political theory have enjoyed canonical status among philosophers in the English-speaking world since at least the early twentieth century. Contrasted with 'Continental rationalism', however, 'British empiricism' is primarily a label of convenience. It signifies neither a single school of thought nor a unified tradition. Not only are there substantial differences of doctrine separating these British empiricists from each other, the similarities in their views on many important matters cohere with those of their rationalist contemporaries on the Continent (Descartes, Leibniz, and Spinoza).

Differences regarding the scope of human knowledge often serve as a convenient if blunt wedge to isolate empiricists and rationalists. However, the assumptions and concepts of seventeenth-century physical science – empiricism in a broader sense – form the bedrock of both traditions. Differences of doctrine are perhaps more fairly seen as innovative philosophical responses to the opportunity afforded by modern science to reexamine human nature and the world to which it belongs. The responses range from rival interpretations of agreed-upon data to significant differences about the very nature of knowledge.

Physics and astronomy together gave both traditions a method for analyzing anew the Aristotelian and scholastic dictum that all knowledge originates with sense-experience. Physicists (e.g., Galileo) portrayed a causal mechanism by which material objects produce such experience. On one side lies matter, which is defined by a handful of primary qualities and whose ultimate components are physical atoms; on the other side is a wide, supersaturated range of 'sensory atoms', called *ideas*, which are the individual colors, sounds, etc., that matter causes the mind to perceive. Both traditions construed ideas as the building blocks of experience, although they used this term with varying degrees of conceptual precision. Inevitably the physical model yields two causally connected domains: the mental world of ideas and the world of material objects which the mind must endeavor to represent. Empiricists and rationalists equally recognized the philosophical challenge to provide a systematic account that unites these domains. Although the philosophers differed in scientific expertise, they all began with ideas and worked outward from the body. Introspection was their accepted method of observation, and many of the arguments in both traditions confidently rely on the assumption that one's own occurrent ideas closely match what others experience. But their explanations differ notably regarding how body and mind are related and, indeed, where the mental domain begins. Locke and Berkeley offered fundamentally opposed accounts, as did Descartes and Spinoza. Locke and Descartes sought to retain two distinct domains. Hobbes and Berkeley aimed to assimilate one to the other, though each favored a different domain. The metaphysics of empiricism seems more complex than the science itself.

British empiricism is often characterized as hewing to the principle that all knowledge derives from sense-experience, in strong opposition to rationalism's doctrine that a priori knowledge (including the innate ideas of Descartes) is an important supplementary source. The first book of Locke's *Essay* inveighs against this doctrine. But not even Hume attempted to show that knowledge of logical principles is based on matters of fact, and Locke himself (in his fourth book) argues for a kind of certainty that does not require empirical support. On the whole, within the historical period of British empiricism, the existence and relevance of a priori knowledge (such as found in logic, mathematics, and geometry) was an accepted component of the empiricism of both traditions, though far less systematically deployed by the empiricists.

British empiricists. See BRITISH EMPIRICISM, RATIONALISM.

Broad, C(harlie) D(unbar) (1887–1971), English epistemologist, metaphysician, moral philosopher, and philosopher of science. He was educated at Trinity College, Cambridge, taught at several universities in Scotland, and then returned to Trinity, first as lecturer in moral science and eventually as Knightbridge Professor of Moral Philosophy. His philosophical views are in the broadly realist tradition of Moore and Russell, though with substantial influence also from his teachers at Cambridge, McTaggart and W. E. Johnson. Broad wrote voluminously and incisively on an extremely wide range of philosophical topics, including most prominently the nature of perception, a priori knowledge and concepts, the problem of induction, the mind-body problem, the free will problem, various topics in moral philosophy, the nature and philosophical significance of psychical research, the nature of philosophy itself, and various historical figures such as Leibniz, Kant, and McTaggart.

Broad's work in the philosophy of perception centers on the nature of sense-data (or *sensa*, as he calls them) and their relation to physical objects. He defends a rather cautious, tentative version of the causal theory of perception. With regard to a priori knowledge, Broad rejects the empiricist view that all such knowledge is of analytic propositions, claiming instead that reason can intuit necessary and universal connections between properties or characteristics; his view of concept acquisition is that while most concepts are abstracted from experience, some are a priori, though not necessarily innate. Broad holds that the rationality of inductive inference depends on a further general premise about the world, a more complicated version of the thesis that nature is uniform, which is difficult to state precisely and even more difficult to justify.

Broad's view of the mind-body problem is a version of dualism, though one that places primary emphasis on individual mental events, is much more uncertain about the existence and nature of the mind as a substance, and is quite sympathetic to epiphenomenalism. His main contribution to the free will problem consists in an elaborate analysis of the libertarian conception of freedom, which he holds to be both impossible to realize and at the same time quite possibly an essential precondition of the ordinary conception of obligation. Broad's work in ethics is diverse and difficult to summarize, but much of it centers on the issue of whether ethical judgments are genuinely cognitive in character.

Broad was one of the few philosophers to take psychical research seriously. He served as president of the Society for Psychical Research and was an occasional observer of experiments in this area. His philosophical writings on this subject, while not uncritical, are in the main sympathetic and are largely concerned to defend concepts like precognition against charges of incoherence and also to draw out their implications for more familiar philosophical issues.

As regards the nature of philosophy, Broad distinguishes between "critical" and "speculative" philosophy. Critical philosophy is analysis of the basic concepts of ordinary life and of science, roughly in the tradition of Moore and Russell. A very high proportion of Broad's own work consists of such analyses, often amazingly detailed and meticulous in character. But he is also sympathetic to the speculative attempt to arrive at an overall conception of the nature of the universe and the position of human beings therein, while at the same time expressing doubts that anything even remotely approaching demonstration is possible in such endeavors.

The foregoing catalog of views reveals something of the range of Broad's philosophical thought, but it fails to bring out what is most strikingly valuable about it. Broad's positions on various issues do not form anything like a system (he himself is reported to have said that there is nothing that answers to the description "Broad's philosophy"). While his views are invariably subtle, thoughtful, and critically penetrating, they rarely have the sort of one-sided novelty that has come to be so highly valued in philosophy. What they do have is exceptional clarity, dialectical insight, and evenhandedness. Broad's skill at uncovering and displaying the precise shape of a philosophical issue, clarifying the relevant arguments and objections, and cataloging in detail the merits and demerits of the opposing positions has rarely been equaled. One who seeks a clear-cut resolution of an issue is likely to be impatient and disappointed with Broad's careful, measured discussions, in which unusual effort is made to accord all positions and arguments their due. But one who seeks a comprehensive and balanced understanding of the issue in question is unlikely to find a more trustworthy guide.

See also PARAPSYCHOLOGY, PHILOSOPHY OF MIND. L.B.

Broome, John (b.1947), British philosopher and economist best known for his work on consequentialist ethics and applications thereof to population bioethics and global warming, and also for his work on rationality, normativity, and reasoning. Broome received a doctorate in economics from MIT (1972) and at this writing is White's Professor of Moral Philosophy at the University of Oxford. His early philosophical papers explored the connection between economic theory and ethical theory, many of which later appeared in *Ethics Out of Economics* (1999).

Broome is one of an important group of British philosophers who in the late 1980s and early 1990s spurred a revival of interest in sophisticated consequentialist ethical theories. Broome's *Weighing Goods: Equality, Uncertainty, and Time* (1991) has become a modern classic of utilitarianism. Broome took up distributive ethics again in *Weighing Lives* (2004). It extends his earlier work to include comparisons of the value of distributions across populations of varying size and membership. After publishing an early book on the ethics of climate change, *Counting the Cost of Global Warming*, he became a lead author for Working Group III of the United Nations International Panel on Climate Change. In *Climate Matters: Ethics in a Warming World* (2012) Broome argues that, principally, governments and public institutions, but also individuals, are obligated to present, and future people to reduce, greenhouse gas emissions.

Broome has also been a central figure in recent work on normativity and rationality. His early papers (e.g., "Normative Requirements," *Ratio*, 1999) stress the importance of focusing on *ought*s in addition to reasons and jointly form the contemporary *locus classicus* for a defense of the wide-scope view of rational requirements. Later work by Broome emphasizes the independence of rationality from normative reasons, sets out the logic of requirements, and explores the nature of theoretical and practical reasoning. He develops a comprehensive account of rationality and reasoning in *Rationality through Reasoning* (2013).

A.Rei.

Brouwer, Luitzgen Egbertus Jan (1881–1966), Dutch mathematician and philosopher and founder of the intuitionist school in the philosophy of mathematics. Educated at the Municipal University of Amsterdam, where he received his doctorate in 1907, he remained there for his entire professional career, as *Privaat-Docent* (1909–12) and then professor (1912–55). He was among the preeminent topologists of his time, proving several important results. Philosophically, he was also unique in his strongly held conviction that philosophical ideas and arguments concerning the nature of mathematics ought to affect and be reflected in its practice.

His general orientation in the philosophy of mathematics was Kantian. This was manifested in his radical critique of the role accorded to logical reasoning by classical mathematics; a role that Brouwer, following Kant, believed to be incompatible with the role that intuition must properly play in mathematical reasoning. The best-known, if not the most fundamental, part of his critique of the role accorded to logic by classical mathematics was his attack on the principle of the excluded middle and related principles of classical logic. He challenged their reliability, arguing that their unrestricted use leads to results that, intuitionistically speaking, are not true.

However, in its fundaments, Brouwer's critique was not so much an attack on particular principles of classical logic as a criticism of the general role that classical mathematics grants to logical reasoning. He believed that logical structure (and hence logical inference) is a product of the linguistic representation of mathematical thought and not a feature of that thought itself. He stated this view in the so-called First Act of Intuitionism, which contains not only the chief critical idea of Brouwer's position, but also its core positive element. This positive element says, with Kant, that mathematics is an essentially language-less activity of the mind. (Brouwer went on to say something with which Kant would have only partially agreed: that this activity has its origin in the perception of a move of time.) The critical element complements this by saying that mathematics is thus to be kept wholly distinct from mathematical language and the phenomena of language described by logic.

The so-called Second Act of Intuitionism then extends the positive part of the First Act by stating that the "self-unfolding" of the primordial intuition of a move of time is the basis not only of the construction of the natural numbers but also of the (intuitionistic) continuum. Together, these two ideas form the basis of Brouwer's philosophy of mathematics – a philosophy that is radically at odds with most of twentieth-century philosophy of mathematics.

See also PHILOSOPHY OF MATHEMATICS. M.D.

Bruno, Giordano (1548–1600), Italian speculative philosopher. He was born in Naples, where he entered the Dominican order in 1565. In 1576 he was suspected of heresy and abandoned his order. He studied and taught in Geneva, but left because of difficulties with the Calvinists. Thereafter he studied and taught in Toulouse, Paris, England, various German universities, and Prague. In 1591 he rashly returned to Venice, and was arrested by the Venetian Inquisition in 1592. In 1593 he was handed over to the Roman Inquisition, which burned him to death as a heretic. Because of his unhappy end, his support for the Copernican heliocentric hypothesis, and his pronounced anti-Aristotelianism, Bruno has been mistakenly seen as the proponent of a scientific worldview against medieval obscurantism. In fact, he should be interpreted in the context of Renaissance hermetism. Indeed, Bruno was so impressed by the hermetic corpus, a body of writings attributed to the mythical Egyptian sage Hermes Trismegistus, that he called for a return to the magical religion of the Egyptians. He was also strongly influenced by Lull, Nicholas of Cusa, Ficino, and Agrippa von Nettesheim, an early sixteenth-century author of an influential treatise on magic. Several of Bruno's works were devoted to magic, and it plays an important role in his books on the art of memory. Techniques for improving the memory had long been a subject of discussion, but he linked them with the notion that one could so imprint images of the universe on the mind as to achieve special knowledge of divine realities and the magic powers associated with such knowledge. He emphasized the importance of the imagination as a cognitive power, since it brings us into contact with the divine. Nonetheless, he also held that human ideas are mere shadows of divine ideas, and that God is transcendent and hence incomprehensible.

Bruno's best-known works are the Italian dialogues he wrote while in England, including the following, all published in 1584: *The Ash Wednesday Supper; On Cause, Principle and Unity; The Expulsion of the Triumphant Beast;* and *On the Infinite Universe and Worlds*. He presents a vision of the universe as a living and infinitely extended unity containing innumerable worlds, each of which is like a great animal with a life of its own. He maintained the unity of matter with universal form, or the World-Soul, thus suggesting a kind of pantheism attractive to later German idealists, such as Schelling. However, he never identified the World-Soul with God, who remained separate from matter and form. He combined his speculative philosophy of nature with the recommendation of a new naturalistic ethics. Bruno's support of Copernicus in *The Ash Wednesday Supper* was related to his belief that a living earth must move, and he specifically rejected any appeal to mere mathematics to prove cosmological hypotheses. In later work he described the monad as a living version of the Democritean atom. Despite some obvious parallels with both Spinoza and Leibniz, he seems not to have had much direct influence on seventeenth-century thinkers. E.J.A.

Brunschvicg, Léon (1869–1944), French philosopher, an influential professor at the Sorbonne and the École Normale Supérieure of Paris, and a founder of the *Revue de Métaphysique et de Morale* (1893) and the Société Française de Philosophie (1901). In 1940 he was forced by the Nazis to leave Paris and sought refuge in the non-occupied zone, where he died. A monistic idealist, Brunschvicg unfolded a philosophy of mind (*Introduction to the Life of the Mind*, 1900). His epistemology highlights judgment. Thinking is judging and judging is acting. He defined philosophy as "the mind's methodical self-reflection." Philosophy investigates man's growing self-understanding. The mind's recesses, or metaphysical truth, are accessible through analysis of the mind's timely manifestations. His major works therefore describe the progress of science as progress of consciousness: *The Stages of Mathematical Philosophy* (1912), *Human Experience and Physical Causality* (1922), *The Progress of Conscience in Western Philosophy* (1927), and *Ages of Intelligence* (1934). An heir of Renouvier, Cournot, and Revaisson, Brunschvicg advocated a moral and spiritual conception of science and attempted to reconcile idealism and positivism. J.-L.S.

brute, in metaphysical discourse, the characteristic that a fact, property, or state of affairs has if it is not explicable by, or grounded in, any more basic fact, property, or state of affairs. Arguably, there must be at least some brute facts (barring infinite regresses of explanation), although this would be denied by adherents of the principle of sufficient reason (e.g., Leibniz). However, this seems to presuppose that no fact can be self-explicable, or grounded in itself, and thus that explanation and grounding are irreflexive and asymmetrical relations, as opposed to antisymmetrical relations. (A relation *R* is irreflexive just in case for any object, *x*, in *R*'s domain, *x* is not *R* to *x*; *R* is asymmetrical just in case if *x* is *R* to *y*, then *y* is not *R* to *x;* and *R* is antisymmetrical just in case if *x* is *R* to *y* and *y* is *R* to *x*, then *x* is identical with *y*.) It might be supposed that self-explicability is ruled out by the general requirement that explanations be non-circular. However, it is not entirely clear that circular explanations must always be vicious, at least if the circle is of a special character. If explanation is an antisymmetrical relation, circular explanations involving more than one fact may still be ruled out, without ruling out self-explanation altogether. Suppose, as many consider plausible, that explanation is transitive, so that if *x* explains *y* and *y* explains *z*, then *x* explains *z*. Then, clearly, if *x* explains *y* and *y* explains *z*, but *z* also explains *x*, giving us a circle of explanation, transitivity implies that *x* explains *x* and thus that *x* is self-explicable. However, we may rule out a circular explanation of this kind while still accepting that there may be cases in which *x* directly explains itself, without the mediation of other facts. So there may still be room for the idea that some (but not all) facts are self-explicable. Certainly, it is common in everyday conversation to *say* that something is 'self-explanatory' – although by this it may merely be meant that the explanation is so obvious as to need no elaboration. However, even if some facts were strictly and literally self-explanatory in a direct fashion – God's existence might conceivably be such a fact, since he is said to be *causa sui* (his own cause) – this would not rule out the possibility of there also being brute facts, lacking any explanation or ground whatever. What might be an example of such a fact? Some would say that the fact that there is something rather than nothing is a brute fact. Others contend that there could not have been nothing and offer putative explanations for this supposed modal fact. Even if there are brute facts, there may be no guarantee that we have a reliable way of identifying them. **See also** EXPLANATION, GROUNDING, STATE OF AFFAIRS. E.J.L.

Buber, Martin (1878–1965), German Jewish philosopher, theologian, and political leader. Buber's early influences include Hasidism and neo-Kantianism. Eventually he broke with the latter and became known as a leading religious existentialist. His chief philosophic works include his most famous book, *Ich und du* ("I and Thou," 1923); *Moses* (1946); *Between Man and Man* (1947); and *Eclipse of God* (1952).

The crux of Buber's thought is his conception of two primary relationships: I-Thou and I-It. I-Thou is characterized by openness, reciprocity, and a deep sense of personal involvement. The I confronts its Thou not as something to be studied, measured, or manipulated, but as a unique presence that responds to the I in its individuality. I-It is characterized by the tendency to treat something as an impersonal object governed by causal, social, or economic forces. Buber rejects the idea that people are isolated, autonomous agents operating according to abstract rules. Instead, reality arises *between* agents as they encounter and transform each other. In a word, reality is dialogical. Buber describes God as the ultimate Thou, the Thou who can never become an It. Thus God is reached not by inference but by a willingness to respond to the concrete reality of the divine presence.

Buchmanism, also called the Moral Rearmament Movement, a non-creedal international movement that sought to bring about universal brotherhood through a commitment to an objectivist moral system derived largely from the Gospels. It was founded by Frank Buchman (1878–1961), an American Lutheran minister who resigned from his church in 1908 in order to expand his ministry. To promote the movement, Buchman founded the Oxford Group at Oxford University in 1921. L.P.P.

buckpassing. See SCANLON.

Buddha (from Sanskrit, 'the enlightened one'), a title (but not a name) of Siddhārta Gotama (c.563–c.483 B.C.), the historical founder of Buddhism, and of any of his later representations. 'Buddha' can also mean anyone who has attained the state of enlightenment (Buddhahood) sought in Buddhism. The Pali Canon mentions twenty-four Buddhas.

Siddhārta Gotama was the son of the ruler of a small state in what is now Nepal. Tradition says that he left home at the age of twenty-nine to seek enlightenment, achieved it at the age of thirty-five, and was a wandering teacher until his death at eighty. He found ready-made in Indian culture the ideas of karma ('fruits of action') and *samsāra* ('wheel of rebirth') as well as the view that escape from the wheel is the highest good, and offered his own Buddhist way of escape. **See also** BUDDHISM. K.E.Y.

Buddhagosa (fourth–fifth century A.D.), Theravada Buddhist philosopher whose major work was the *Visuddhimagga* ("Path of Purification"). He accepted the typical Buddhist doctrine that everything that exists (Nirvana aside) is impermanent and momentary. A mind at a moment is only a momentary collection of momentary states; over time it is a series of such collections; similarly for a physical object. He held that, through sensory perception, physical objects are known to exist mind-independently. To the objection that perception of an object cannot occur in a moment since perception requires memory, attention, recognition, examination, and the like, he theorized that there is physical time and there is mental time; a single physical moment passes while distinct mental moments mount to sixteen in number. Hence a complex perceptual process can occur within a series of mental moments while a single material moment passes. Critics (e.g., Buddhist Yogācāra philosophers) saw in this a denial of impermanence. **See also** BUDDHISM. K.E.Y.

Buddhism, a religion of eastern and central Asia founded by Siddhārta Gotama Buddha. He found ready-made in Indian culture the ideas of karma ('fruits of action'), *samsāra* ('wheel of rebirth'), and escape from the wheel as the highest good. Buddhist doctrine, like that of other Indian religions, offers its distinctive way to achieve that end. It teaches that at the core of the problem is desire or craving – for wealth, pleasure, power, continued existence – which fuels the flame of continued life. It adds that the solution is the snuffing out of craving by following the Eightfold Path (right speech, action, livelihood, effort, mindfulness, concentration, views, and intentions). The idea is that intuitive wisdom follows upon moral conduct and mental discipline in accord with Buddhist precepts. This involves accepting these claims: all existence is unsatisfactory (*dukkha*); all existence is impermanent (*anicca*); and there is no permanent self (*anatta*). Along with these claims go the doctrines of momentariness (everything that exists is transitory, lasting only a moment) and codependent origination (everything that exists does so dependently on other things).

Since God is typically conceived in monotheistic religions as existing independently and as either eternal or everlasting, there is no room within a Buddhist perspective for monotheism. Save for a heretical school, Buddhist traditions also reject all belief in substances. A substance, in this sense, is something that has properties, is not itself a property or a collection of properties, and endures through time. The obvious contrast to the Buddhist perspective is the notion of a self in Hinduism and Jainism, which is beginningless and endless, an indestructible entity sometimes conceived as inherently self-conscious and sometimes viewed as conscious only when embodied. But even the notion of a substance that endured but had a beginning or end or both, or a substance that existed dependently and endured so long as its sustaining conditions obtained, would run deep against the grain of typical Buddhist teaching.

The Buddha is said to have offered no opinion, and to have found no profit in speculation, on certain questions: whether the world is or is not eternal, whether the world is or is not infinite, and whether the soul is different from or identical to the body. The religious reason given for this indifference is that reflection on such matters does not lead to enlightenment. A philosophical reason sometimes given is that if, as Buddhism claims, there is no world of substances, whether minds or bodies, then these questions have no straightforward answer. They are like the question, What does the horn of the hare weigh? Hares have no horns to be heavy or light. Seen in the context of the assumptions common in the culture in which they were asked, the questions would suggest that there are substantival minds and bodies and a world made up of them, and to answer these questions, even negatively, would involve at least implicitly sanctioning that suggestion.

Broadly, Indian Buddhism divides into *Theravada* ('Doctrine of the Elders', namely those who heard and followed the Buddha; this school is also called *Hinayana*, or 'Lesser Vehicle') and *Mahayana* ('Greater Vehicle'). The Sautrāntika and Vaibhāsika schools belong to Theravada and the Mādhyamika and Yogācarā schools are Mahayana.

The Theravada schools. The Sautrāntika school holds that while sensory experience justifies belief in the existence of mind-independent objects, the justification it provides requires us to infer from our sensory experience physical objects that we do not directly experience; it embraces *representative realism*. Thus, while our seeming to experience mind-independent objects is no illusion, our knowledge that it is not illusory rests as much on inference as on perception. The explanation of the fact that we cannot perceive as we wish – that we see and taste but rice and water though we would prefer meat and wine – is that what we see depends on what there is to be represented and what the conditions are under which we do our perceiving.

The Vaibhāsika (followers of the *Vaibhāsha* commentary) school defends direct realism, contending that if sensory perception does not justify us in claiming actually to sense objects there is no way in which we can infer their existence. If what we directly experience are alleged representations or copies of objects we never see, from which we must then infer the objects copied, we have no reason to think that the copies *are* copies of anything. We do not determine the content of our perception because it typically is determined for us by the objects that we see. The very distinctions between dreams and waking perceptions, or veridical perceptions and illusions, to which idealists appeal, depend for their appropriateness to the idealist's purpose on our being able to tell that some perceptual experiences are reliable and some are not; but then the idealist cannot successfully use them. For both Theravada schools, there is no need to correct our belief in physical objects, or in minds, beyond our viewing both minds and objects as collections of (different sorts of) momentary states.

The Mahayana schools. The Mādhyamika school holds out for a more radical revision. Our experience of physical objects is reliable only if the beliefs that we properly base on it are true – only if things are as they sensorily seem. These beliefs are true only if we can sensorily distinguish between individual objects. But everything exists dependently, and nothing that exists dependently is an individual. So there are no individuals and we cannot distinguish between individual objects. So our sensory experience is not reliable, but rather is systematically illusory. Mādhyamika then adds the doctrine of an ineffable ultimate reality hidden behind our ordinary experience and descriptions, which is accessible only in esoteric enlightenment experience. In this respect it is like Advaita Vedanta, which it probably influenced. One result of the overall Mādhyamika teaching described here is that Nirvana and *samsāra*, the goal and ordinary life, are identified; roughly *samsāra* is how Nirvana seems to the unenlightened (as roughly, for Advaita, the world of dependent things is how quality-less Brahman appears to the unenlightened).

The Yogācāra (perhaps 'Yoga' because it used meditation to remove belief in mind-independent physical objects) school of Mahayana Buddhism contends for a more ambitious revision of our beliefs about objects than does Sautrāntika or Vaibhāsika, but a less radical one than the Mādhyamika. Against the latter, it contends that if mind itself is empty of essence and if all there is, is an ineffable reality, then there is no one to see the truth and no reliable way to discover it. Against the direct physical-object realism of the Vaibhāsika and the representational realism of the Sautrāntika, the Yogācāra philosophers argue that dream experience seems to be of objects that exist mind-independently and in a public space, and yet there are no such objects and there is no such space. What we have experiential evidence for is the existence of (non-substantival) minds and the experiences that those minds have. There are no substances at all and no physical states; there are only mental states that compose minds. Yogācāra philosophers too had to explain why our perceptual content is not something we can decide by whim, and its explanation came in terms of the theory that each collection of momentary states, and hence each series or stream of such collections, contains impressions that represent past experiences. These impressions become potent under certain circumstances and determine the content of one's explicit or conscious perception. The stream, or substream, of representative impressions is a storehouse of memories and plays a role in Yogācāra theory analogous to that of the *Ātman* or *Jīva* in some of the schools of Hinduism. Critics suspected it of being a thin surrogate for a substantival self. Asanga, Dignāga, and especially Vasubandhu were leading Yogācāra philosophers. Further, critics of the Yogācāra idealism argued that while the view contends that there are minds other than one's own, it provided no way in which that belief could be justified.

Our discussion has dealt with Indian Buddhism. Buddhism largely died out in India around the thirteenth century. It thrived in other places, especially China, Tibet, and Japan. Japanese Pure Land Buddhism resembles monotheism more than do any of the traditions that we have discussed. *Zen* is a form of Mahayana that developed in China in the sixth and seventh centuries A.D. and spread to Japan. It involves esoteric teachings outside the sacred writings, following which is believed to lead to realization of Buddhahood.

The metaphysical and epistemological issues briefly discussed here demonstrate that the Buddhist tradition found it natural to trace the consequences of views about the nature of objects and persons, and about what experience teaches, beyond the scope of what Buddhism as a religion might strictly require. There are direct realists, representational realists, and idealists, and the question arises as to whether idealism slides into solipsism. There is no way of telling what a particular religious doctrine may or may not be related to. Arguably, certain Buddhist doctrines are incompatible with certain views in contemporary physics (and Buddhist apologists have claimed that contemporary physics provides some sort of confirmation of basic Buddhist categories). There is no a priori way to limit the relationships that may come to light between apparently very diverse, and quite unrelated, issues and doctrines.

bundle theory, a view that accepts the idea that concrete objects consist of properties but denies the need for introducing substrata to account for their diversity. By contrast, one traditional view of concrete particular objects is that they are complexes consisting of two more fundamental kinds of entities: properties that can be exemplified by many different objects and a substratum that exemplifies those properties belonging to a particular object. Properties account for the *qualitative identity* of such objects while substrata account for their *numerical diversity*.

The bundle theory is usually glossed as the view that a concrete object is nothing but a bundle of properties. This gloss, however, is inadequate. For if a "bundle" of properties is, e.g., a *set* of properties, then bundles of properties differ in significant ways from concrete objects. For sets of properties are *necessary* and *eternal* while concrete objects are *contingent* and *perishing*.

A more adequate statement of the theory holds that a concrete object is a complex of properties which all stand in a fundamental contingent relation, call it *co-instantiation*, to one another. On this account, complexes of properties are neither necessary nor eternal. Critics of the theory, however, maintain that such complexes have all their properties *essentially* and cannot change properties, whereas concrete objects have some of their properties *accidentally* and undergo change. This objection fails to recognize that there are two distinct problems addressed by the bundle theory: (a) individuation and (b) identity through time. The first problem arises for *all* objects, both momentary and enduring. The second, however, arises only for enduring objects. The bundle theory typically offers two different solutions to these problems. An *enduring* concrete object is analyzed as a series of momentary objects which stand in some contingent relation *R*. Different versions of the theory offer differing accounts of the relation. For example, Hume holds that the self is a series of co-instantiated impressions and ideas, whose members are related to one another by causation and resemblance (this is his bundle theory of the self). A *momentary* object, however, is analyzed as a complex of properties all of which stand in the relation of co-instantiation to one another. Thus, even if one grants that a momentary complex of properties has all of its members essentially, it does not follow that an enduring object, which contains the complex as a temporal part, has those properties essentially unless one endorses the controversial thesis that an enduring object has its temporal parts essentially. Similarly, even if one grants that a momentary complex of properties cannot change in its properties, it does not follow that an enduring object, which consists of such complexes, cannot change in its properties.

Critics of the bundle theory argue that its analysis of momentary objects is also problematic. For it appears possible that two *different momentary objects* have all properties in common, yet there cannot be two *different complexes* with all properties in common. There are two responses available to a proponent of the theory. The first is to distinguish between a strong and a weak version of the theory. On the strong version, the thesis that a momentary object is a complex of co-instantiated properties is a *necessary truth*, while on the weak version it is a *contingent* truth. The *possibility* of two momentary objects with all properties in common impugns only the strong version of the theory. The second is to challenge the basis of the claim that it is possible for two momentary objects to have all their properties in common. Although critics allege that such a state of affairs is conceivable, proponents argue that investigation into the nature of conceivability does not underwrite this claim.

Burge, Tyler (b.1946), American philosopher highly influential in the philosophies of mind, psychology, and language, as well as epistemology and the history of philosophy. Burge investigates, both a priori and empirically, the nature and epistemology of sensation, perception, memory, introspection, self-knowledge, reason, critical reason, reflection, personhood, understanding, and communication. Burge's early work examined proper names, mass terms, demonstratives, truth, and epistemic and semantic paradoxes.

Burge is best known for anti-individualism (externalism) concerning the natures of many representational mental states. Anti-individualism takes many representational states to depend constitutively on their relations to a wider environment. To support anti-individualism, he develops Twin-Earth-style thought experiments involving incomplete understanding, nonstandard theory, and physical and social relations. He argues that perceptual anti-individualism is presupposed by perceptual psychology and best explains perceptual representational content (*Foundations of Mind*, 2007; *Origins of Objectivity*, 2010).

Burge distinguishes sensation from perception, perception from reason, and reason from critical reason. He rejects deflationary accounts of perception that blur it with sensation as well as hyper-intellectualized accounts that require reason for perceptual reference (*Origins*). He rejects naive realism and disjunctivism about perception ("Disjunctivism and Perceptual Psychology," 2010).

In epistemology, Burge develops teleological reliabilism concerning warrant. Warrant consists in meeting norms of adequacy in fulfilling representational functions. Warrant entails nonaccidental reliability in normal conditions. Burge distinguishes two subspecies: entitlement and justification. *Justifications* involve reasons within the individual's psychology. *Entitlements* are warrants without reasons. The distinction undermines hyper-intellectualization in epistemology ("Perceptual Entitlement," 2003; *Cognition Through Understanding*, 2013).

In the history of philosophy, Burge engages Descartes, Leibniz, Kant, and Frege. He has written extensively on Frege, emphasizing Frege's rationalism and Frege's distinction between sense and linguistic meaning (*Truth, Thought, Reason*, 2005).

P.J.Gr.

Buridan, Jean (c.1300–after 1358), French philosopher. He was born in Béthune and educated at the University of Paris. Unlike most philosophers of his time, Buridan spent his academic career as a master in the faculty of arts, without seeking an advanced degree in theology. He was also unusual in being a secular cleric rather than a member of a religious order.

Buridan wrote extensively on logic and natural philosophy, although only a few of his works have appeared in modern editions. The most important on logic are the *Summulae de dialectica* ("Sum of Dialectic"), an introduction to logic conceived as a revision of, and extended commentary on, the *Summulae logicales* of Peter of Spain, a widely used logic textbook of the period; and the *Tractatus de consequentiis*, a treatise on modes of inference. Most of Buridan's other writings are short literal commentaries (*expositiones*) and longer critical studies (*quaestiones*) of Aristotle's works.

Like most medieval nominalists, Buridan argued that universals have no real existence, except as concepts by which the mind "conceives of many things indifferently." Likewise, he included only particular substances and qualities in his basic ontology. But his nominalist program is distinctive in its implementation. He differs, e.g., from Ockham in his accounts of motion, time, and quantity (appealing, in the latter case, to quantitative forms to explain the impenetrability of bodies). In natural philosophy, Buridan is best known for introducing to the West the non-Aristotelian concept of impetus, or impressed force, to explain projectile motion. Although asses appear often in his examples, the particular example that has come (via Spinoza and others) to be known as "Buridan's ass," an ass starving to death between two equidistant and equally tempting piles of hay, is unknown in Buridan's writings. It may, however, have originated as a caricature of Buridan's theory of action, which attempts to find a middle ground between Aristotelian intellectualism and Franciscan voluntarism by arguing that the will's freedom to act consists primarily in its ability to defer choice in the absence of a compelling reason to act one way or the other.

Buridan's intellectual legacy was considerable. His works continued to be read and discussed in universities for centuries after his death. Three of his students and disciples, Albert of Saxony, Marsilius of Inghen, and Nicole Oresme, went on to become distinguished philosophers in their own right.

Buridan's ass. See BURIDAN.

Burke, Edmund (1729–97), British statesman and one of the eighteenth century's greatest political writers. Born in Dublin, he moved to London to study law, then undertook a literary and political career. He sat in the House of Commons from 1765 to 1794. In speeches and pamphlets during these years he offered an ideological perspective on politics that endures to this day as the fountain of conservative wisdom.

The philosophical stance that pervades Burke's parliamentary career and writings is skepticism, a profound distrust of political rationalism – i.e., the achievement in the political realm of abstract and rational structures, ideals, and objectives. Burkean skeptics are profoundly anti-ideological, detesting what they consider the complex, mysterious, and existential givens of political life distorted, criticized, or planned from a perspective of abstract, generalized, and rational categories. The seminal expression of Burke's skeptical conservatism is found in the *Reflections on the Revolution in France* (1790). The conservatism of the *Reflections* was earlier displayed, however, in Burke's response to radical demands in England for democratic reform of Parliament in the early 1780s. The English radicals assumed that legislators could remake governments, when all wise men knew that "a prescriptive government never was made upon any foregone theory." How ridiculous, then, to put governments on Procrustean beds and make them fit "the theories which learned and speculative men have made." Such prideful presumption required much more rational capacity than could be found among ordinary mortals.

One victim of Burke's skepticism is the vaunted liberal idea of the social contract. Commonwealths were neither constructed nor ought they to be renovated according to a priori principles. The concept of an original act of contract is just such a principle. The only contract in politics is the agreement that binds generations past, present, and future, one that "is but a clause in the great primeval contract of an eternal society." Burke rejects the voluntaristic quality of rationalist liberal contractualism. Individuals are not free to create their own political institutions. Political society and law are not "subject to the will of those who, by an obligation above them, and infinitely superior, are bound to submit their will to that law." Men and groups "are not morally at liberty, at their pleasure, and on their speculations of a contingent improvement" to rip apart their communities and dissolve them into an "unsocial, uncivil, unconnected chaos."

Burke saw our stock of reason as small; despite this people still fled their basic limitations in flights of ideological fancy. They recognized no barrier to their powers and sought in politics to make reality match their speculative visions. Burke devoutly wished that people would appreciate their weakness, their "subordinate rank in the creation." God has "subjected us to act the part which belongs to the place assigned us." And that place is to know the limits of one's rational and speculative faculties.

Instead of relying on their own meager supply of reason, politicians should avail themselves "of the general bank and capital of nations and of ages." Because people forget this they weave rational schemes of reform far beyond their power to implement.

Burke stands as the champion of political skepticism in revolt against Enlightenment rationalism and its "smugness of adulterated metaphysics," which produced the "revolution of doctrine and theoretic dogma." The sins of the French were produced by the "clumsy subtlety of their political metaphysics." The "faith in the dogmatism of philosophers" led them to rely on reason and abstract ideas, on speculation and a priori principles of natural right, freedom, and equality as the basis for reforming governments. Englishmen, like Burke, had no such illusions; they understood the complexity and fragility of human nature and human institutions, they were not "the converts of Rousseau . . . the disciples of Voltaire; Helvetius [had] made no progress amongst [them]."

See also POLITICAL PHILOSOPHY. I.K.

Burley, Walter (c.1275–c.1344), English philosopher who taught philosophy at Oxford and theology at Paris. An orthodox Aristotelian and a realist, he attacked Ockham's logic and his interpretation of the Aristotelian categories. Burley commented on almost of all of Aristotle's works in logic, natural philosophy, and moral philosophy.

An early Oxford Calculator, Burley began his work as a fellow of Merton College in 1301. By 1310 he was at Paris. A student of Thomas Wilton, he probably incepted before 1322; by 1324 he was a fellow of the Sorbonne. His commentary on Peter Lombard's *Sentences* has been lost. After leaving Paris, Burley was associated with the household of Richard of Bury and the court of Edward III, who sent him as an envoy to the papal curia in 1327. *De vita et moribus philosophorum* ("On the Life and Manners of Philosophers"), an influential, popular account of the lives of the philosophers, has often been attributed to Burley, but modern scholarship suggests that the attribution is incorrect.

Many of Burley's independent works dealt with problems in natural philosophy, notably *De intensione et remissione formarum* ("On the Intension and Remission of Forms"), *De potentiis animae* ("On the Faculties of the Soul"), and *De substantia orbis. De primo et ultimo instanti* ("On First and Last Instants") discusses which temporal processes have intrinsic, which extrinsic limits. In his *Tractatus de formis* Burley attacks Ockham's theory of quantity. Similarly, Burley's theory of motion opposed Ockham's views. Ockham restricts the account of motion to the thing moving, and the quality, quantity, and place acquired by motion. By contrast, Burley emphasizes the process of motion and the quantitative measurement of that process. Burley attacks the view that the forms successively acquired in motion are included in the form finally acquired. He ridicules the view that contrary qualities (hot and cold) could simultaneously inhere in the same subject producing intermediate qualities (warmth).

Burley emphasized the formal character of logic in his *De puritate artis logicae* ("On the Purity of the Art of Logic"), one of the great medieval treatises on logic. Ockham attacked a preliminary version of *De puritate* in his *Summa logicae;* Burley called Ockham a beginner in logic. In *De puritate artis logicae*, Burley makes syllogistics a subdivision of consequences. His treatment of negation is particularly interesting for his views on double negation and the restrictions on the rule that not-not-p implies p. Burley distinguished between analogous words and analogous concepts and natures. His theory of analogy deserves detailed discussion. These views, like the views expressed in most of Burley's works, have seldom been carefully studied by modern philosophers.

See also OCKHAM, PETER LOMBARD. R.W.

business ethics, the field of applied ethics whose core subjects are the moral legitimacy and normative functions of business, justice within business organizations, and the obligations of managers and business professionals to diverse stakeholders. It is a multidisciplinary research field, encompassing psychological, sociological, and organizational scholarship in addition to conceptual and normative scholarship. Contemporary philosophical work in business ethics is distinctive in typically taking into account social science research and legal scholarship rather than engaging in theory development independently of research by economists, organizational and industrial psychologists, sociologists, management scholars, and legal scholars. The scope of business ethics as a field is *micro*, *meso*, and *macro*.

At the micro level philosophical business ethics addresses such issues as the role of virtue in organizational life and the principles that should guide managers. Some scholars argue that virtue, understood as positive character traits, enhances the ability to compete in a capitalist marketplace. For example, practical reason has been defended as a virtue necessary for the good governance of organizations. Other scholars argue that competiveness undermines the ability of businesspeople to exhibit virtue. Still other scholars argue that a virtuous business life provides meaningfulness to work in a way that a corrupt business life does not. Social scientific analysis of the role of virtue in organizational life is likely necessary to help adjudicate some of these theoretical disputes.

Increasing attention has also been paid to the principles that should guide managers in business life. Like bioethicists who defend the idea that specific ethical principles should guide the practice of medicine, philosophers have defended the idea that ethical principles should guide the management of organizations, businesses in particular. It has been shown that particularist objections citing the indeterminacy of ethical principles in specific cases can be met with Kantian resources (as argued by J. Smith and W. Dubbink). Ethical principles may be understood as values worthy of endorsement that provide motivation but must be implemented case by case. In an organizational context, ethical principles can be utilized to produce organizational values statements and policies and to inform incentive structures. The internalization of ethical principles by employees is itself a manifestation of a type of virtue.

At a meso level the field focuses on organizational ontology, organizational justice, organizational legitimacy, ethical organizational cultures and practices, justice in compensation, and organizational responsibility in relation to various stakeholders and the environment, among other subjects. Whether corporations are properly regarded as collective agents and whether moral responsibility is properly attributable to corporations rather than merely to individual employees have been subjects of ongoing debate for at least thirty-five years. There appears to be some agreement among many scholars that corporate policies and corporate internal decision structures confer agency (though not personhood) on corporations but that such agency is compatible with the claim that individual employees or executives are properly held responsible for their actions as a part of that decision structure.

Perhaps the most important problems in business ethics, and the ones that have contributed to the most substantial body of literature, revolve around the fiduciary duty of managers to act on behalf of shareholders of publicly traded corporations and the relationship of those duties to competing duties to other stakeholders (as argued by Edward Freeman and others). The duty to maximize profits for shareholders is regarded by the majority of scholars in fields such as economics and finance, at least those who concern themselves with the problem, as not merely a legal duty but a moral duty. The duty is typically grounded in consequentialist reasoning, but the arguments that would support a duty to shareholders (or other owners of a business such as private equity investors) over and above all other possible ethical duties have largely gone undefended. The standard story is that property rights and liberty rights allow for the legitimate exchange of property and for labor constrained by contracts freely entered into, or else are protected by exit rights in capitalist markets. However, factors such as background injustice, deception, negative externalities, and political influences on the regulation of business interests undermine the standard story and create the need for more complex analysis of market exchanges regarding a range of ethical problems.

The normative legitimacy of business is particularly a problem for businesses operating internationally in a variety of political contexts and with widely varying background conditions of justice. Scholars with libertarian sympathies typically emphasize the positive role of foreign direct investment in enhancing the welfare of developing nations. They tend to defend low wages, poor working conditions, and lax environmental standards on the grounds that the jobs and other benefits do not make anyone worse off, while at the same time they enhance the well-being of workers by providing them with employment opportunities, provide consumers in industrial nations with inexpensive goods, and enhance shareholder wealth. Critics of multinational corporations tend to emphasize the diminished autonomy of impoverished workers, basic human rights, and negative externalities.

Business ethicists have sought to articulate universal norms to guide international business and have developed several theoretical frameworks that provide the grounds for the normative legitimacy of business organizations. One of the best developed is integrative social contracts theory, which grounds legitimacy in "hypernorms" established by macro-social contractors who are aware of both their political and economic preferences. On this model a convergence of religious, cultural, and philosophical beliefs produces a range of substantive norms while allowing for a range of micro-social contracts in particular economic communities. However, this theoretical framework has been criticized for permitting a variety of counterintuitive hypernorms such as gender discrimination and slavery. In its place, theorists have sought alternative theoretical basis for international business, including a deliberative democracy framework grounded in Habermas and a Rawlsian global justice framework. More recently a cosmopolitan human rights perspective has been defended. This development coincides with the emergence of a human rights framework for business supported by the United Nations and other international organizations.

At a macro level the field parallels some elements of political philosophy and public policy by taking up questions regarding the legitimacy of different varieties of capitalism, property rights, the regulatory frameworks that ought to govern businesses, and the appropriate role of businesses in political processes.

In recent years the concept of *sustainability* has become an increasingly common focus in organizational ethics and should be understood as distinct from the concept of sustainable development. In an organizational context the concept sometimes refers to environmental sustainability alone – where the emphasis is on conducting business in a way that, relative to environmental constraints (such as consumption of raw material), is possible long term – and sometimes to both environmental and social sustainability. While these concepts are not yet well defined, social sustainability typically refers to ethical consideration for stakeholders – taking account of their long-term interests – while environmental sustainability relative to business can be understood as the internalization of the costs of negative environmental externalities.

Butler, Joseph (1692–1752), English theologian and Anglican bishop who made important contributions to moral philosophy, to the understanding of moral agency, and to the development of deontological ethics. Better known in his own time for *The Analogy of Religion* (1736), a defense, along broadly empiricist lines, of orthodox, "revealed" Christian doctrine against deist criticism, Butler's main philosophical legacy was a series of highly influential arguments and theses contained in a collection titled *Sermons* (1725) and in two "Dissertations" appended to *The Analogy* – one on virtue and the other on personal identity. The analytical method of these essays ("everything is what it is and not another thing") provided a model for much of English-speaking moral philosophy to follow. For example, Butler is often credited with refuting *psychological hedonism*, the view that all motives can be reduced to the desire for pleasure or happiness. The sources of human motivation are complex and structurally various, he argued. Appetites and passions seek their own peculiar objects, and pleasure must itself be understood as involving an intrinsic positive regard for a particular object. Other philosophers had maintained, like Butler, that we can desire, e.g., the happiness of others intrinsically, and not just as a means to our own happiness. And others had argued that those who aim single-mindedly at their own happiness are unlikely to attain it. Butler's distinctive contribution was to demonstrate that happiness and pleasure themselves require completion by specific objects for which we have an intrinsic positive regard. Self-love, the desire for our own happiness, is a *reflective* desire for, roughly, the satisfaction of our other desires. But self-love is not our only reflective desire; we also have "a settled reasonable principle of benevolence." We can consider the goods of others and come on reflection to desire their welfare more or less independently of particular emotional involvement such as compassion.

In morals, Butler equally opposed attempts to reduce virtue to benevolence, even of the most universal and impartial sort. Benevolence seeks the good or happiness of others, whereas the regulative principle of virtue is conscience, the faculty of moral approval or disapproval of conduct and character. Moral agency requires, he argued, the capacities to reflect disinterestedly on action, motive, and character, to judge these in distinctively moral terms (and not just in terms of their relation to the non-moral good of happiness), and to guide conduct by such judgments. Butler's views about the centrality of conscience in the moral life were important in the development of deontological ethics as well as in the working out of an associated account of moral agency. Along the first lines, he argued in the "Dissertation" that what it is right for a person to do depends, not just on the (non-morally) good or bad consequences of an action, but on such other morally relevant features as the relationships the agent bears to affected others (e.g., friend or beneficiary), or whether fraud, injustice, treachery, or violence is involved. Butler thus distinguished analytically between distinctively moral evaluation of action and assessing an act's relation to such non-moral values as happiness. And he provided succeeding deontological theorists with a litany of examples where the right thing to do is apparently not what would have the best consequences.

Butler believed God instills a "principle of reflection" or conscience in us through which we intrinsically disapprove of such actions as fraud and injustice. But he also believed that God, being omniscient and benevolent, fitted us with these moral attitudes because "He foresaw this constitution of our nature would produce more happiness, than forming us with a temper of mere general benevolence." This points, however, toward a kind of anti-deontological or consequentialist view, sometimes called *indirect consequentialism*, which readily acknowledges that what it is right to do does not depend on which *act* will have the best consequences. It is entirely appropriate, according to indirect consequentialism, that conscience approve or disapprove of acts on grounds other than a calculation of consequences precisely because its doing so has the best consequences. Here we have a version of the sort of view later to be found, e.g., in Mill's defense of utilitarianism against the objection that it conflicts with justice and rights. Morality is a system of social control that demands allegiance to considerations other than utility, e.g. justice and honesty. But it is justifiable only to the extent that the system itself has utility.

This sets up something of a tension. From the conscientious perspective an agent must distinguish between the question of which action would have the best consequences and the question of what he should do. And from that perspective, Butler thinks, one will necessarily regard one's answer to the second question as authoritative for conduct. Conscience necessarily implicitly asserts its own authority, Butler famously claimed. Thus, insofar as agents come to regard their conscience as simply a method of social control with good consequences, they will come to be alienated from the inherent authority their conscience implicitly claims. A similar issue arises concerning the relation between conscience and self-love. Butler says that both self-love and conscience are "superior principles in the nature of man" in that an action will be unsuitable to a person's nature if it is contrary to either. This makes conscience's authority conditional on its not conflicting with self-love (and vice versa). Some scholars, moreover, read other passages as implying that no agent could reasonably follow conscience unless doing so was in the agent's interest. But again, it would seem that an agent who internalized such a view would be alienated from the authority that, if Butler is right, conscience implicitly claims. For Butler, conscience or the principle of reflection is uniquely the faculty of practical *judgment*. Unlike either self-love or benevolence, even when these are added to the powers of inference and empirical cognition, only conscience makes moral agency possible. Only a creature with conscience can accord with or violate his own judgment of what he ought to do, and thereby be a "law to himself." This suggests a view that, like Kant's, seeks to link deontology to a conception of autonomous moral agency.

C

cabala (from Hebrew *qabbala*, 'tradition'), a system of Jewish mysticism and theosophy practiced from the thirteenth to the eighteenth century; loosely all forms of Jewish mysticism. Believed by its adherents to be a tradition communicated to Moses at Sinai, the main body of cabalistic writing, the *Zohar*, is thought to be the work primarily of Moses de León of Guadalajara, in the thirteenth century, though he attributed it to the second-century rabbi Simon bar Yohai. The *Zohar* builds on earlier Jewish mysticism, and is replete with gnostic and Neoplatonic themes. It offers the initiated access to the mysteries of God's being, human destiny, and the meaning of the commandments. The transcendent and strictly unitary God of rabbinic Judaism here encounters ten apparently real divine powers, called *sefirot*, which together represent God's being and appearance in the cosmos and include male and female principles. Evil in the world is seen as a reflection of a cosmic rupture in this system, and redemption on earth entails restoration of the divine order. Mankind can assist in this task through knowledge, piety, and observance of the law.

Isaac Luria in the sixteenth century developed these themes with graphic descriptions of the dramas of creation, cosmic rupture, and restoration, the latter process requiring human assistance more than ever. A.L.I.

Caird, Edward (1835–1908), Scottish philosopher, a leading absolute idealist. Influential as both a writer and a teacher, Caird was professor of moral philosophy at Glasgow and master of Balliol College, Oxford. His aim in philosophy was to overcome intellectual oppositions. In his main work, *The Critical Philosophy of Kant* (1889), he argued that Kant had done this by using reason to synthesize rationalism and empiricism while reconciling science and religion. In Caird's view, Kant unfortunately treated reason as subjective, thereby retaining an opposition between self and world. Loosely following Hegel, Caird claimed that objective reason, or the Absolute, was a larger whole in which both self and world were fragments. In his *Evolution of Religion* (1893) Caird argued that religion progressively understands God as the Absolute and hence as what reconciles self and world. This allowed him to defend Christianity as the highest evolutionary stage of religion without defending the literal truth of Scripture. **See also** **IDEALISM**, **PHILOSOPHY OF RELIGION.** J.W.A.

Cajetan, original name, Tommaso de Vio (c.1469–1534), Italian prelate and theologian. Born in Gaeta (from which he took his name), he entered the Dominican order in 1484 and studied philosophy and theology at Naples, Bologna, and Padua. He became a cardinal in 1517; during the following two years he traveled to Germany, where he engaged in a theological controversy with Luther. His major work is a *Commentary on St. Thomas' Summa of Theology* (1508), which promoted a renewal of interest in Scholastic and Thomistic philosophy during the sixteenth century. In agreement with Aquinas, Cajetan places the origin of human knowledge in sense perception. In contrast with Aquinas, he denies that the immortality of the soul and the existence of God as our creator can be proved. Cajetan's work in logic was based on traditional Aristotelian syllogistic logic but is original in its discussion of the notion of analogy. Cajetan distinguishes three types: analogy of inequality, analogy of attribution, and analogy of proportion. Whereas he rejected the first two as improper, he regarded the last as the basic type of analogy and appealed to it in explaining how humans come to know God and how analogical reasoning applied to God and God's creatures avoids being equivocal. **See also** **THOMISM.** P.Gar.

calculi of relations. See RELATIONAL LOGIC.

calculus, a central branch of mathematics, originally conceived in connection with the determination of the tangent (or normal) to a curve and of the area between it and some fixed axis; but it also embraced the calculation of volumes and of areas of curved surfaces, the lengths of curved lines, etc. *Mathematical analysis* is a still broader branch that subsumed the calculus under its rubric (see below), together with the theories of functions and of infinite series. Still more general and/or abstract versions of analysis have been developed during the twentieth century, with applications to other branches of mathematics, such as probability theory.

The origins of the calculus go back to Greek mathematics, usually in problems of determining the slope of a tangent to a curve and the area enclosed underneath it by some fixed axes or by a closed curve; sometimes related questions such as the length of an arc of a curve, or the area of a curved surface, were considered. The subject flourished in the seventeenth century when the analytical geometry of Descartes gave algebraic means to extend the procedures. It developed further when the problems of slope and area were seen to require the finding of new functions, and that the pertaining processes were seen to be inverse. Newton and Leibniz had these insights in the late seventeenth century, independently and in different forms.

In the Leibnizian *differential calculus* the differential dx was proposed as an infinitesimal increment on x, and of the same dimension as x; the slope of the tangent to a curve with y as a function of x was the *ratio* dy/dx. The *integral,* $\int x$, was infinitely large and of the dimension of x; thus for linear variables x and y the area $\int y\, dx$ was the sum of the areas of rectangles y high and dx wide. All these quantities were variable, and so could admit higher-order differentials and integrals (ddx, $\int\int x$, etc.). This theory was extended during the eighteenth century, especially by Euler, to functions of several independent variables, and with the creation of the calculus of variations. The chief motivation was to solve differential equations: they were motivated largely by problems in mechanics, which was then the single largest branch of mathematics.

Newton's less successful *fluxional calculus* used limits in its basic definitions, thereby changing dimensions for the defined terms. The fluxion was the rate of change of a variable quantity relative to "time"; conversely, that variable was the "fluent" of its fluxion. These quantities were also variable; fluxions and fluents of higher orders could be defined from them.

A third tradition was developed during the late eighteenth century by J. L. Lagrange. For him the "derived functions" of a function $f(x)$ were definable by purely algebraic means from its Taylorian power-series expansion about any value of x. By these means it was hoped to avoid the use of both infinitesimals and limits, which exhibited conceptual difficulties, the former due to their unclear ontology as values greater than zero but smaller than any orthodox quantity, the latter because of the naive theories of their deployment.

In the early nineteenth century the Newtonian tradition died away, and Lagrange's did not gain general conviction; however, the Leibniz-Euler line kept some of its health, for its utility in physical applications. But all these theories gradually became eclipsed by the mathematical analysis of A. L. Cauchy. As with Newton's calculus, the theory of limits was central, but they were handled in a much more sophisticated way. He replaced the usual practice of defining the integral as (more or less) *automatically* the inverse of the differential (or fluxion or whatever) by giving *independent* definitions of the derivative and the integral; thus for the first time the fundamental "theorem" of the calculus, stating their inverse relationship, became a genuine theorem, requiring sufficient conditions upon the function to ensure its truth. Indeed, Cauchy pioneered the routine specification of necessary and/or sufficient conditions for truth of theorems in analysis. His discipline also incorporated the theory of (dis)continuous functions and the convergence or divergence of infinite series. Again, general definitions were proffered and conditions sought for properties to hold.

Cauchy's discipline was refined and extended in the second half of the nineteenth century by K. Weierstrass and his followers at Berlin. The study of existence theorems (as for irrational numbers), and also technical questions largely concerned with trigonometric series, led to the emergence of set topology. In addition, special attention was given to processes involving several variables changing in value together, and as a result the importance of quantifiers was recognized – e.g., reversing their order from 'there is a y such that for all x . . .' to 'for all x, there is a y . . .'. This developed later into general set theory, and then to mathematical logic: Cantor was the major figure in the first aspect, while G. Peano pioneered much for the second.

Under this regime of "rigor," infinitesimals such as dx became unacceptable as mathematical objects. However, they always kept an unofficial place because of their utility when applying the calculus, and since World War II theories have been put forward in which the established level of rigor and generality is preserved (and even improved) but in which infinitesimals are reinstated. The best known of these theories, the non-standard analysis of A. Robinson, makes use of model theory by defining infinitesimals as arithmetical inverses of the transfinite integers generated by a "non-standard model" of Peano's postulates for the natural numbers.

Calvin, John (1509–64), French theologian and church reformer, a major figure in the Protestant Reformation. He was especially important for the so-called Reformed churches in France, Switzerland, the Netherlands, Germany, Scotland, and England. Calvin was a theologian in the humanist tradition rather than a philosopher. He valued philosophy as "a noble gift of God" and cited philosophers (especially Plato) when it suited his purposes; but he rejected philosophical speculation about "higher things" and despised – though sometimes exploiting its resources – the dominant (Scholastic) philosophy of his time, to which he had been introduced at the University of Paris. His eclectic culture also included a variety of philosophical ideas, of whose source he was often unaware, that inevitably helped to shape his thought. His *Christianae religionis institutio* (1st ed. 1536, but repeatedly enlarged; in English generally cited as *Institutes*), his theological treatises, his massive biblical commentaries, and his letters, all of which were translated into most European languages, thus helped to transmit various philosophical motifs and attitudes in an unsystematic form both to contemporaries and to posterity. He passed on to his followers impulses derived from both the *antiqui* and the *moderni*.

From the former he inherited an intellectualist anthropology that conceived of the personality as a hierarchy of faculties properly subordinated to reason, which was at odds with his evangelical theology; and, though he professed to scorn Stoicism, a moralism often more Stoic than evangelical. He also relied occasionally on the Scholastic *quaestio*, and regularly treated substantives, like the *antiqui*, as real entities. These elements in his thought also found expression in tendencies to a natural theology based on an innate and universal religious instinct that can discern evidences of the existence and attributes of God everywhere in nature, and a conception of the Deity as immutable and intelligible. This side of Calvinism eventually found expression in Unitarianism and universalism.

It was, however, in uneasy tension with other tendencies in his thought that reflect both his biblicism and a nominalist and Scotist sense of the extreme transcendence of God. Like other humanists, therefore, he was also profoundly skeptical about the capacity of the human mind to grasp ultimate truth, an attitude that rested, for him, on both the consequences of original sin and the merely conventional origins of language. Corollaries of this were his sense of the contingency of all human intellectual constructions and a tendency to emphasize the utility rather than the truth even of such major elements in his theology as the doctrine of predestination. It may well be no accident, therefore, that later skepticism and pragmatism have been conspicuous in thinkers nurtured by later Calvinism, such as Bayle, Hume, and James.

Cambridge change, a non-genuine change. If I turn pale, I am changing, whereas your turning pale is only a Cambridge change in me. When I acquire the property of being such that you are pale, *I* do not change. In general, an object's acquiring a new property is not a sufficient condition for that object to change (although some *other* object may genuinely change). Thus also, my being such that you are pale counts only as a *Cambridge property* of me, a property such that my gaining or losing it is only a Cambridge change. Cambridge properties are a proper subclass of extrinsic properties: being south of Chicago is considered an extrinsic property of me, but since my moving to Canada would be a genuine change, being south of Chicago cannot, for me, be a Cambridge property.

The concept of a Cambridge change reflects a way of thinking entrenched in common sense, but it is difficult to clarify, and its philosophical value is controversial. Neither science nor formal semantics, e.g., supports this viewpoint. Perhaps Cambridge changes and properties are, for better or worse, inseparable from a vague, intuitive metaphysics.

Cambridge Platonists, a group of seventeenth-century philosopher-theologians at the University of Cambridge, principally including Benjamin Whichcote (1609–83), often designated the father of the Cambridge Platonists; Henry More; Ralph Cudworth (1617–88); and John Smith (1616–52). Whichcote, Cudworth, and Smith received their university education in or were at some time fellows of Emmanuel College, a stronghold of the Calvinism in which they were nurtured and against which they rebelled under mainly Erasmian, Arminian, and Neoplatonic influences. Other Cambridge men who shared their ideas and attitudes to varying degrees were Nathanael Culverwel (1618–51), Peter Sterry (1613–72), George Rust (d.1670), John Worthington (1618–71), and Simon Patrick (1625–1707).

As a generic label, 'Cambridge Platonists' is a handy umbrella term rather than a dependable signal of doctrinal unity or affiliation. The Cambridge Platonists were not a self-constituted group articled to an explicit manifesto; no two of them shared quite the same set of doctrines or values. Their Platonism was not exclusively the pristine teaching of Plato, but was formed rather from Platonic ideas supposedly prefigured in Hermes Trismegistus, in the Chaldean Oracles, and in Pythagoras, and which they found in Origen and other church fathers, in the Neoplatonism of Plotinus and Proclus, and in the Florentine Neoplatonism of Ficino. They took contrasting and changing positions on the important belief (originating in Florence with Giovanni Pico della Mirandola) that Pythagoras and Plato derived their wisdom ultimately from Moses and the cabala. They were not equally committed to philosophical pursuits, nor were they equally versed in the new philosophies and scientific advances of the time.

The Cambridge Platonists' concerns were ultimately religious and theological rather than primarily philosophical. They philosophized as theologians, making eclectic use of philosophical doctrines (whether Platonic or not) for apologetic purposes. They wanted to defend "true religion," namely, their latitudinarian vision of Anglican Christianity, against a variety of enemies: the Calvinist doctrine of predestination; sectarianism; religious enthusiasm; fanaticism; the "hidebound, strait-laced spirit" of Interregnum Puritanism; the "narrow, persecuting spirit" that followed the Restoration; atheism; and the impieties incipient in certain trends in contemporary science and philosophy. Notable among the latter were the doctrines of the mechanical philosophers, especially the materialism and mechanical determinism of Hobbes and the mechanistic pretensions of the Cartesians.

The existence of God, the existence, immortality, and dignity of the human soul, the existence of spirit activating the natural world, human free will, and the primacy of reason are among the principal teachings of the Cambridge Platonists. They emphasized the positive role of reason in all aspects of philosophy, religion, and ethics, insisting in particular that it is *ir*rationality that endangers the Christian life. Human reason and understanding was "the Candle of the Lord" (Whichcote's phrase), perhaps their most cherished image. In Whichcote's words, "To go against Reason, is to go against God. . . . Reason is the Divine Governor of Man's Life; it is the very Voice of God." Accordingly, "there is no real clashing at all betwixt any genuine point of Christianity and what true Philosophy and right Reason does determine or allow" (More). Reason directs us to the self-evidence of first principles, which "must be seen in their own light, and are perceived by an inward power of nature." Yet in keeping with the Plotinian mystical tenor of their thought, they found within the human soul the "Divine Sagacity" (More's term), which is the prime cause of human reason and therefore superior to it. Denying the Calvinist doctrine that revelation is the only source of spiritual light, they taught that the "natural light" enables us to know God and interpret the Scriptures.

Cambridge Platonism was uncompromisingly innatist. Human reason has inherited immutable intellectual, moral, and religious notions, "anticipations of the soul," which negate the claims of empiricism. The Cambridge Platonists were skeptical with regard to certain kinds of knowledge, and recognized the role of skepticism as a critical instrument in epistemology. But they were dismissive of the idea that Pyrrhonism be taken seriously in the practical affairs of the philosopher at work, and especially of the Christian soul in its quest for divine knowledge and understanding. Truth is not compromised by our inability to devise apodictic demonstrations. Indeed Whichcote passed a moral censure on those who pretend "the doubtfulness and uncertainty of reason."

Innatism and the natural light of reason shaped the Cambridge Platonists' moral philosophy. The unchangeable and eternal ideas of good and evil in the divine mind are the exemplars of ethical axioms or noemata that enable the human mind to make moral judgments. More argued for a "boniform faculty," a faculty higher than reason by which the soul rejoices in reason's judgment of the good.

The most philosophically committed and systematic of the group were More, Cudworth, and Culverwel. Smith, perhaps the most intellectually gifted and certainly the most promising (note his dates), defended Whichcote's Christian teaching, insisting that theology is more "a Divine Life than a Divine Science." More exclusively theological in their leanings were Whichcote, who wrote little of solid philosophical interest; Rust, who followed Cudworth's moral philosophy; and Sterry. Only Patrick, More, and Cudworth (all fellows of the Royal Society) were sufficiently attracted to the new science (especially the work of Descartes) to discuss it in any detail or to turn it to philosophical and theological advantage. Though often described as a Platonist, Culverwel was really a neo-Aristotelian with Platonic embellishments and, like Sterry, a Calvinist. He denied innate ideas and supported the *tabula rasa* doctrine, commending "the Platonists . . . that they lookt upon the spirit of a man as the Candle of the Lord, though they were deceived in the time when 'twas lighted."

The Cambridge Platonists were influential as latitudinarians, as advocates of rational theology, as severe critics of unbridled mechanism and materialism, and as the initiators, in England, of the intuitionist ethical tradition. In the England of Locke they are a striking counterinstance of innatism and non-empirical philosophy.

camera obscura, a darkened enclosure that focuses light from an external object by a pinpoint hole instead of a lens, creating an inverted, reversed image on the opposite wall. The adoption of the camera obscura as a model for the eye revolutionized the study of visual perception by rendering obsolete previous speculative philosophical theories, in particular the emanation theory, which explained perception as due to emanated copy-images of objects entering the eye, and theories that located the image of perception in the lens rather than the retina. By shifting the location of sensation to a projection on the retina, the camera obscura doctrine helped support the distinction of primary and secondary sense qualities, undermining the medieval realist view of perception and moving toward the idea that consciousness is radically split from the world. **See also** PERCEPTION. T.H.L.

Campanella, Tommaso (1568–1639), Italian theologian, philosopher, and poet. He joined the Dominican order in 1582. Most of the years between 1592 and 1634 he spent in prison for heresy and for conspiring to replace Spanish rule in southern Italy with a utopian republic. He fled to France in 1634 and spent his last years in freedom. Some of his best poetry was written while he was chained in a dungeon; and during less rigorous confinement he managed to write over a hundred books, not all of which survive. His best-known work, *The City of the Sun* (1602; published 1623), describes a community governed in accordance with astrological principles, with a priest as head of state. In later political writings, Campanella attacked Machiavelli and called for either a universal Spanish monarchy with the pope as spiritual head or a universal theocracy with the pope as both spiritual and temporal leader. His first publication was *Philosophy Demonstrated by the Senses* (1591), which supported the theories of Telesio and initiated his lifelong attack on Aristotelianism. He hoped to found a new Christian philosophy based on the two books of nature and Scripture, both of which are manifestations of God. While he appealed to sense experience, he was not a straightforward empiricist, for he saw the natural world as alive and sentient, and he thought of magic as a tool for utilizing natural processes. In this he was strongly influenced by Ficino. Despite his own difficulties with Rome, he wrote in support of Galileo. **See also** FICINO, TELESIO. E.J.A.

Campbell, Norman Robert (1880–1949), British physicist and philosopher of science. A successful experimental physicist, Campbell (with A. Wood) discovered the radioactivity of potassium. His analysis of science depended on a sharp distinction between experimental laws and theories. Experimental laws are generalizations established by observations. A theory has the following structure. First, it requires a (largely arbitrary) hypothesis, which in itself is untestable. To render it testable, the theory requires a "dictionary" of propositions linking the hypothesis to scientific laws, which can be established experimentally. But theories are not merely logical relations between hypotheses and experimental laws; they also require concrete analogies or models.

Indeed, the models suggest the nature of the propositions in the dictionary. The analogies are essential components of the theory and, for Campbell, are nearly always mechanical. His theory of science greatly influenced Nagel's *The Structure of Science* (1961). **See also** PHILOSOPHY OF SCIENCE, THEORETICAL TERM. R.E.B.

Camus, Albert (1913–60), French philosophical novelist and essayist who was also a prose poet and the conscience of his times. He was born and raised in Algeria, and his experiences as a fatherless, tubercular youth, as a young playwright and journalist in Algiers, and later in the anti-German resistance in Paris during World War II informed everything he wrote. His best-known writings are not overtly political; his most famous works, the novel *The Stranger* (written in 1940, published in 1942) and his book-length essay *The Myth of Sisyphus* (written in 1941, published in 1943) explore the notion of 'the absurd', which Camus alternatively describes as the human condition and as "a widespread sensitivity of our times." The absurd, briefly defined, is the confrontation between ourselves – with our demands for rationality and justice – and an "indifferent universe." Sisyphus, who was condemned by the gods to the endless, futile task of rolling a rock up a mountain (whence it would roll back down of its own weight), thus becomes an exemplar of the human condition, struggling hopelessly and pointlessly to achieve something. The odd antihero of *The Stranger*, on the other hand, unconsciously accepts the absurdity of life. He makes no judgments, accepts the most repulsive characters as his friends and neighbors, and remains unmoved by the death of his mother and his own killing of a man. Facing execution for his crime, he "opens his heart to the benign indifference of the universe."

But such stoic acceptance is not the message of Camus's philosophy. Sisyphus thrives (he is even "happy") by virtue of his scorn and defiance of the gods, and by virtue of a "rebellion" that refuses to give in to despair. This same theme motivates Camus's later novel, *The Plague* (1947), and his long essay *The Rebel* (1951). In his last work, however, a novel called *The Fall* published in 1956, the year before he won the Nobel Prize in Literature, Camus presents an unforgettably perverse character named Jean-Baptiste Clamence, who exemplifies all the bitterness and despair rejected by his previous characters and in his earlier essays. Clamence, like the character in *The Stranger*, refuses to judge people, but whereas Meursault (the "stranger") is incapable of judgment, Clamence (who was once a lawyer) makes it a matter of philosophical principle, "for who among us is innocent?" It is unclear where Camus's thinking was heading when he was killed in an automobile accident (with his publisher, Gallimard, who survived).

Canguilhem, Georges (1904–96), French historian and philosopher of science. Canguilhem succeeded Gaston Bachelard as director of the Institut d'Histoire des Sciences et des Techniques at the University of Paris. He developed and sometimes revised Bachelard's view of science, extending it to issues in the biological and medical sciences, where he focused particularly on the concepts of the normal and the pathological (*The Normal and the Pathological*, 1966). On his account norms are not objective in the sense of being derived from value-neutral scientific inquiry, but are rooted in the biological reality of the organisms that they regulate.

Canguilhem also introduced an important methodological distinction between concepts and theories. Rejecting the common view that scientific concepts are simply functions of the theories in which they are embedded, he argued that the use of concepts to interpret data is quite distinct from the use of theories to explain the data. Hence the same concepts may occur in very different theoretical contexts. Canguilhem made particularly effective use of this distinction in tracing the origin of the concept of reflex action.

Cantor, Georg (1845–1918), German mathematician, one of a number of late nineteenth-century mathematicians and philosophers (including Frege, Dedekind, Peano, Russell, and Hilbert) who transformed both mathematics and the study of its philosophical foundations. The philosophical import of Cantor's work is threefold. First, it was primarily Cantor who turned arbitrary collections into objects of mathematical study, sets. Second, he created a coherent *mathematical* theory of the infinite, in particular a theory of transfinite numbers. Third, linking these, he was the first to indicate that it might be possible to present mathematics as nothing but the theory of sets, thus making set theory foundational for mathematics. This contributed to the view that the foundations of mathematics should itself become an object of mathematical study. Cantor also held to a form of principle of plenitude, the belief that all the infinities given in his theory of transfinite numbers are represented not just in mathematical (or "immanent" reality), but also in the "transient" reality of God's created world.

Cantor's main, direct achievement is his theory of transfinite numbers and infinity. He characterized (as did Frege) sameness of size in terms of one-to-one correspondence, thus accepting the paradoxical results known to Galileo and others, e.g., that the collection of *all* natural numbers has the same cardinality or size as that of all *even* numbers. He added to these surprising results by showing (1874) that there is the same number of algebraic (and thus rational) numbers as there are natural numbers, but that there are *more* points on a continuous line than there are natural (or rational or algebraic) numbers, thus revealing that there are at least two different kinds of infinity present in ordinary mathematics, and consequently demonstrating the need for a mathematical treatment of these infinities. This latter result is often expressed by saying that the continuum is *uncountable. Cantor's theorem* of 1892 is a generalization of part of this, for it says that the set of all subsets (the *power-set*) of a given set must be cardinally greater than that set, thus giving rise to the possibility of indefinitely many different infinities. (The collection of all real numbers has the same size as the power-set of natural numbers.) Cantor's theory of transfinite numbers (1880–97) was his developed mathematical theory of infinity, with the infinite cardinal numbers (the ℵ-, or aleph-, numbers) based on the infinite ordinal numbers that he introduced in 1880 and 1883. The ℵ-numbers are in effect the cardinalities of infinite *well-ordered* sets. The theory thus generates two famous questions, whether *all* sets (in particular the continuum) can be well ordered, and if so which of the ℵ-numbers represents the cardinality of the continuum. The former question was answered positively by Zermelo in 1904, though at the expense of postulating one of the most controversial principles in the history of mathematics, the axiom of choice. The latter question is the celebrated *continuum problem*. Cantor's famous *continuum hypothesis* (CH) is his conjecture that the cardinality of the continuum is represented by $\aleph_1$, the second aleph. CH was shown to be independent of the usual assumptions of set theory by Gödel (1938) and Cohen (1963). Extensions of Cohen's methods show that it is consistent to assume that the cardinality of the continuum is given by almost any of the vast array of ℵ-numbers. The continuum problem is now widely considered insoluble.

Cantor's conception of set is often taken to admit the whole universe of sets as a set, thus engendering contradiction, in particular in the form of *Cantor's paradox*. For Cantor's theorem would say that the power-set of the universe must be bigger than it, while, since this power-set is a set of sets, it must be *contained* in the universal set, and thus can be no bigger. However, it follows from Cantor's early (1883) considerations of what he called the "absolute infinite" that none of the collections discovered later to be at the base of the paradoxes can be proper sets. Moreover, correspondence with Hilbert in 1897 and Dedekind in 1899 (see Cantor, *Gesammelte Abhandlungen mathematischen und philosophischen Inhalts*, 1932) shows clearly that Cantor was well aware that contradictions will arise if such collections *are* treated as ordinary sets.

cardinal virtues, prudence (practical wisdom), courage, temperance, and justice. Medievals deemed them cardinal (from Latin *cardo*, 'hinge') because of their pivotal role in human flourishing. In Plato's *Republic*, Socrates explains them through a doctrine of the three parts of the soul, suggesting that a person is *prudent* when knowledge of how to live (wisdom) informs her *reason, courageous* when informed reason governs her *capacity for wrath*, temperate when it also governs her *appetites*, and *just* when each part performs its proper task with informed reason in control. Development of thought on the cardinal virtues was closely tied to the doctrine of the unity of the virtues, i.e. that a person possessing one virtue will have them all. **See also** VIRTUE ETHICS. J.L.A.G.

Carlyle, Thomas (1795–1881), Scottish-born essayist, historian, and social critic, one of the most popular writers and lecturers in nineteenth-century Britain. His works include literary criticism, history, and cultural criticism. With respect to philosophy, his views on the theory of history are his most significant contributions. According to Carlyle, great personages are the most important causal factor in history. *On Heroes, Hero-Worship and the Heroic in History* (1841) asserts, "Universal History, the history of what man has accomplished in this world, is at bottom the History of the Great Men who have worked here. They were the leaders of men, these great ones; the modellers, patterns, and in a wide sense creators, of whatsoever the general mass of men contrived to do or to attain; all things that we see standing accomplished in the world are properly the outer material result, the practical realisation and embodiment, of Thoughts that dwelt in the Great Men sent into the world: the soul of the whole world's history, it may justly be considered, were the history of these."

Carlyle's doctrine has been challenged from many directions. Hegelian and Marxist philosophers maintain that the so-called great men of history are not really the engine of history, but merely reflections of deeper forces, such as economic ones, while contemporary historians emphasize the priority of "history from below" – the social history of everyday people – as far more representative of the historical process.

Carnap, Rudolf (1891–1970), German-born American philosopher who was a leader of the Vienna Circle, a movement loosely called logical positivism or logical empiricism. He made fundamental contributions to semantics and the philosophy of science, as well as to the foundations of probability and inductive logic. He was a staunch advocate of, and active in, the unity of science movement.

Carnap received his Ph.D. in philosophy from the University of Jena in 1921. His first major work was *Die Logische Aufbau der Welt* (1928), in which he sought to apply the new logic recently developed by Frege and by Russell and Whitehead to problems in the philosophy of science. Although influential, it was not translated until 1967, when it appeared as *The Logical Structure of the World*. It was important as one of the first clear and unambiguous statements that the important work of philosophy concerned logical structure: that language and its logic were to be the focus of attention. In 1935 Carnap left his native Germany for the United States, where he taught at the University of Chicago and then at UCLA.

Die Logiche Syntax der Sprache (1934) was rapidly translated into English, appearing as *The Logical Syntax of Language* (1937). This was followed in 1941 by *Introduction to Semantics*, and in 1942 by *The Formalization of Logic*. In 1947 *Meaning and Necessity* appeared; it provided the groundwork for a modal logic that mirrored the meticulous semantic development of first-order logic in the first two volumes. One of the most important concepts introduced in these volumes was that of a *state description*. A state description is the linguistic counterpart of a possible world: in a given language, the most complete description of the world that can be given.

Carnap then turned to one of the most pervasive and important problems to arise in both the philosophy of science and the theory of meaning. To say that the meaning of a sentence is given by the conditions under which it would be verified (as the early positivists did) or that a scientific theory is verified by predictions that turn out to be true, is to speak loosely. Absolute verification does not occur. To carry out the program of scientific philosophy in a realistic way, we must be able to speak of the support given by inconclusive evidence, either in providing epistemological justification for scientific knowledge or in characterizing the meanings of many of the terms of our scientific language. This calls for an understanding of probability or, as Carnap preferred to call it, degree of confirmation. We must distinguish between two senses of probability: what he called probability$_1$, corresponding to credibility, and probability$_2$, corresponding to the frequency or empirical conception of probability defended by Reichenbach and von Mises. 'Degree of confirmation' was to be the formal concept corresponding to credibility.

The first book on this subject, written from the same point of view as the works on semantics, was *The Logical Foundations of Probability* (1950). The goal was a logical definition of '$\boldsymbol{c}(h,e)$': the degree of confirmation of a hypothesis h, relative to a body of evidence e, or the degree of rational belief that one whose total evidence was e should commit to h. Of course we must first settle on a formal language in which to express the hypothesis and the evidence; for this Carnap chooses a first-order language based on a finite number of one-place predicates, and a countable number of individual constants. Against this background, we perform the following reductions: '$\boldsymbol{c}(h,e)$' represents a conditional probability; thus it can be represented as the ratio of the absolute probability of h & e to the absolute probability of e. Absolute probabilities are represented by the value of a measure function $\boldsymbol{m}$, defined for sentences of the language. The problem is to define $\boldsymbol{m}$. But every sentence in Carnap's languages is equivalent to a disjunction of state descriptions; the measure to be assigned to it must, according to the probability calculus, be the sum of the measures assigned to its constituent state descriptions. Now the problem is to define $\boldsymbol{m}$ for state descriptions. (Recall that state descriptions were part of the machinery Carnap developed earlier.) The function $\boldsymbol{c}\dagger$ is a confirmation function based on the assignment of equal measures to each state description. It is inadequate, because if h is not entailed by e, $\boldsymbol{c}\dagger(h,e) = \boldsymbol{m}\dagger(h)$, the a priori measure assigned to h. We cannot "learn from experience." A measure that does not have that drawback is $\boldsymbol{m}^*$, which is based on the assignment of equal measures to each structure description. A structure description is a set of state descriptions; two state descriptions belong to the same structure description just in case one can be obtained from the other by a permutation of individual constants. Within the structure description, equal values are assigned to each state description.

In the next book, *The Continuum of Inductive Methods*, Carnap takes the rate at which we learn from experience to be a fundamental parameter of his assignments of probability. Like measures on state descriptions, the values of the probability of the singular predictive inference determine all other probabilities. The "singular predictive inference" is the inference from the observation that individual 1 has one set of properties, individual 2 has another set of properties, etc., to the conclusion: individual j will have property k.

Finally, in the last works (*Studies in Inductive Logic and Probability*, Vols. I [1971] and II [1980], edited with Richard Jeffrey) Carnap offered two long articles constituting his *Basic System of Inductive Logic*. This system is built around a language having families of attributes (e.g., color or sound) that can be captured by predicates. The basic structure is still monadic, and the logic still lacks identity, but there are more parameters. There is a parameter λ that reflects the "rate of learning from experience"; and a parameter η that reflects an inductive relation between values of attributes belonging to families. With the introduction of arbitrary parameters, Carnap was edging toward a subjective or personalistic view of probability. How far he was willing to go down the subjectivist garden path is open to question; that he discovered more to be relevant to inductive logic than the "language" of science seems clear.

Carnap's work on probability measures on formal languages is destined to live for a long time. So too is his work on formal semantics. He was a staunch advocate of the fruitfulness of formal studies in philosophy, of being clear and explicit, and of offering concrete examples. Beyond the particular philosophical doctrines he advocated, these commitments characterize his contribution to philosophy.

Carneades. See academy.

Carroll, Lewis, pen name of Charles Lutwidge Dodgson (1832–98), English writer and mathematician. The eldest son of a large clerical family, he was educated at Rugby and Christ Church, Oxford, where he remained for the rest of his uneventful life, as mathematical lecturer (until 1881) and curator of the senior common room. His mathematical writings (under his own name) are more numerous than important. He was, however, the only Oxonian of his day to contribute to symbolic logic, and is remembered for his syllogistic diagrams, for his methods for constructing and solving elaborate sorites problems, for his early interest in logical paradoxes, and for the many amusing examples that continue to reappear in modern textbooks. Fame descended upon him almost by accident, as the author of *Alice's Adventures in Wonderland* (1865), *Through the Looking Glass* (1872), *The Hunting of the Snark* (1876), and *Sylvie and Bruno* (1889–93); saving the last, the only children's books to bring no blush of embarrassment to an adult reader's cheek.

Dodgson took deacon's orders in 1861, and though pastorally inactive, was in many ways an archetype of the prim Victorian clergyman. His religious opinions were carefully thought out, but not of great philosophic interest. The Oxford movement passed him by; he worried about sin (though rejecting the doctrine of eternal punishment), abhorred profanity, and fussed over Sunday observance, but was oddly tolerant of theatergoing, a lifelong habit of his own. Apart from the sentimental messages later inserted in them, the *Alice* books and *Snark* are blessedly devoid of religious or moral concern. Full of rudeness, aggression, and quarrelsome, if fallacious, argument, they have, on the other hand, a natural attraction for philosophers, who pillage them freely for illustrations. Humpty-Dumpty, the various Kings and Queens, the Mad Hatter, the Caterpillar, the White Rabbit, the Cheshire Cat, the Unicorn, the Tweedle brothers, the Bellman, the Baker, and the Snark make fleeting appearances in the pages of Russell, Moore, Broad, Quine, Nagel, Austin, Ayer, Ryle, Blanshard, and even Wittgenstein (an unlikely admirer of the Mock Turtle). The first such allusion (to the March Hare) is in Venn's *Symbolic Logic* (1881). The usual reasons for quotation are to make some point about meaning, stipulative definition, the logic of negation, time reversal, dream consciousness, the reification of fictions and nonentities, or the absurdities that arise from taking "ordinary language" too literally. (For exponents of word processing, the effect of running 'Jabberwocky' through a spell-checker is to extinguish all hope for the future of artificial intelligence.)

Though he was himself no philosopher, Carroll's unique sense of philosophic humor keeps him (and his illustrator, Sir John Tenniel) effortlessly alive in the modern age. *Alice* has been translated into seventy-five languages; new editions and critical studies appear every year; imitations, parodies, cartoons, quotations, and ephemera proliferate beyond number; and Carroll societies flourish in several countries, notably Britain and the United States. Cartwright, Nancy Delaney (b.1944), American-born joint citizen of the United Kingdom and United States, philosopher of natural and social science, pioneer of practice-based philosophy of science, and member of the influential "Stanford School," known especially for contributions to the understanding of scientific realism and objectivity, the nature and limits of scientific knowledge, causality, modeling, and evidence-based policymaking, and also for her mentoring of young scholars.

Cartwright, an empiricist, argues that the world as imaged – and manipulated – by the sciences is not that pictured by previous generations of empiricists. First, causes and capacities (powers) are not only real, but also primary objects of scientific knowledge. Capacities can be measured, and the methods of modern science make no sense without them. Second, science yields a diverse patchwork of laws, not a unified system thereof. And while "fundamental" laws (e.g., those of physics) may be true, they apply only to those special situations their models fit, hold only *ceteris paribus*, and are generated by systems of components with stable capacities ("nomological machines"). Third, there is no single, correct theory of causation: different kinds of causal systems require different characterizations of causality and different methods for finding causes. Her work on evidence-based policymaking puts her thinking on causality and mechanisms to practical use by explaining what kinds of evidence are necessary for effective policies and why current guides to policymaking generally fail to provide them.

Cartwright is professor of philosophy at Durham University and the University of California, San Diego (since 1998), and previously taught at the London School of Economics (1991–2012) and Stanford University (1973–91). Her major books are *How the Laws of Physics Lie* (1983), *Nature's Capacities and Their Measurement* (1989), *The Dappled World* (1999), *Hunting Causes and Using Them* (2007), and (with Jeremy Hardie) *Evidence-Based Policy* (2012). L.R.

causal theory of action, any causal account of what it is for an agent to do something. Causal theories maintain that performing an action entails that an appropriate internal state of the agent causes a particular result in a certain way. Your leg can move without your moving your leg; a causal theory might maintain that the latter event occurs only if your desire (or intention, or volition), not a seizure, causes your leg to move. The initiating state must produce the result in a specific way, not by a "wayward" or "deviant" causal chain. You do not move your leg if your leg moves because a surgeon secretly wired you so that your desire activates an external pulley that moves it.

Causal theories account for different ways of acting in terms of different causal processes. Moving your leg via its own muscles differs in this way from moving it with your hand. *Voluntary* action (e.g., moving your leg normally) differs from *involuntary* action (e.g., coughing) both in the neural pathways involved and in the initiating state. The distinction between *intentional* and *unintentional* action is similarly explained. Turning on the light is intentional only if the initiating cause is the desire or intention to turn it on. If you turned it on unintentionally, then it came on because you wanted to do something else instead, say turn on the fan. A robot can turn on a light, but cannot do so intentionally because it has no mental states at all.

A causal theory of *reasons* accounts for the distinction between merely having a reason for doing something one does and doing it *for* that reason, in terms of whether the reasons causally connect to the action in the right way. Thus someone whose reason for going to the store was to get bread went there in part as a result of wanting to get bread. Someone who had that reason, but went there for a different reason, also wanted to get bread, but this is not what caused him to go. The causal theory is sometimes characterized as maintaining that reasons *are* causes. But this is implausible and inessential to the theory. In our example, the agent's reason was *to get bread*. The cause was the agent's desiring to get it.

Some causal theorists seek a semantic analysis, hence a noncircular definition of terms like 'intentionally'. Achieving this is not essential to causal theories, and most syntactically unstructured expressions of natural languages, especially those that interest philosophers, are difficult or impossible to define. A difficulty for any semantic causal theory is specifying the right sort of causal chain without either circularity or specialized terminology.

Cārvāka, Indian materialism. Its varieties share the view that the mind is simply the body and its capacities, but differ as to whether every mental property is simply a physical property under some psychological description (reductive materialism) or there are emergent irreducibly mental properties that are caused by physical properties and themselves have no causal impact (epiphenomenalism). Some Cārvāka epistemologists, at least according to their critics, accept only perception as a reliable source of knowledge, but in its most sophisticated form Cārvāka, not unlike logical positivism, allows inference at least to conclusions that concern perceptually accessible states of affairs. **See also** HINDUISM. K.E.Y.

Cassirer, Ernst (1874–1945), German philosopher and intellectual historian. He was born in the German city of Breslau (now Wroclaw, Poland) and educated at various German universities. He completed his studies in 1899 at Marburg under Hermann Cohen, founder of the Marburg School of neo-Kantianism. Cassirer lectured at the University of Berlin from 1906 to 1919, then accepted a professorship at the newly founded University of Hamburg. With the rise of Nazism he left Germany in 1933, going first to a visiting appointment at All Souls College, Oxford (1933–35), and then to a professorship at the University of Göteborg, Sweden (1935–41). In 1941 he went to the United States; he taught first at Yale (1941–44) and then at Columbia (1944–45).

Cassirer's works may be divided into those in the history of philosophy and culture and those that present his own systematic thought. The former include major editions of Leibniz and Kant; his four-volume study *The Problem of Knowledge* (Vols. 1–3, 1906–20; Vol. 4, 1950), which traces the subject from Nicholas of Cusa to the twentieth century; and individual works on Descartes, Leibniz, Kant, Rousseau, Goethe, the Renaissance, the Enlightenment, and English Platonism. The latter include his multivolume *The Philosophy of Symbolic Forms* (1923–29), which presents a philosophy of human culture based on types of symbolism found in myth, language, and mathematical science; and individual works concerned with problems in such fields as logic, psychology, aesthetics, linguistics, and concept formation in the humanities. Two of his best-known works are *An Essay on Man* (1944) and *The Myth of the State* (1946).

Cassirer did not consider his systematic philosophy and his historical studies to be separate endeavors; each grounded the other. Because of his involvement with the Marburg School, his philosophical position is frequently but mistakenly typed as neo-Kantian. Kant had an important influence on him, but so did Hegel, Herder, Wilhelm von Humboldt, Goethe, Leibniz, and Vico. Cassirer derives his principal philosophical concept, *symbolic form*, most directly from Heinrich Hertz's conception of notation in mechanics and the conception of the symbol in art of the Hegelian aesthetician Friedrich Theodor Vischer. In a wider sense his conception of symbolic form is a transformation of 'idea' and 'form' within the whole tradition of philosophical idealism. Cassirer's conception of symbolic form is not based on a distinction between the symbolic and the literal. In his view all human knowledge depends on the power to form experience through some type of symbolism. The forms of human knowledge are coextensive with forms of human culture. Those he most often analyzes are myth and religion, art, language, history, and science. These forms of symbolism constitute a total system of human knowledge and culture that is the subject matter of philosophy.

Cassirer's influence is most evident in the aesthetics of Susanne Langer (1895–1985), but his conception of the symbol has entered into theoretical anthropology, psychology, structural linguistics, literary criticism, myth theory, aesthetics, and phenomenology. His studies of the Renaissance and the Enlightenment still stand as groundbreaking works in intellectual history.

See also HEGEL, LEIBNIZ, NEO-KANTIANISM, VICO. D.P.V.

Castañeda, Hector-Neri (1924–91), American analytical philosopher. Heavily influenced by his own critical reaction to Quine, Chisholm, and his teacher Wilfrid Sellars, Castañeda published four books and more than 175 essays. His work combines originality, rigor, and penetration, together with an unusual comprehensiveness – his network of theory and criticism reaches into nearly every area of philosophy, including action theory; deontic logic and practical reason; ethics; history of philosophy; metaphysics and ontology; philosophical methodology; philosophy of language, mind, and perception; and the theory of knowledge. His principal contributions are to metaphysics and ontology, indexical reference, and deontic logic and practical reasoning.

In metaphysics and ontology, Castañeda's chief work is guise theory, first articulated in a 1974 essay, a complex and global account of language, mind, ontology, and predication. By holding that ordinary concrete individuals, properties, and propositions all break down or separate into their various aspects or guises, he theorizes that thinking and reference are directed toward the latter. Each guise is a genuine item in the ontological inventory, having properties internally and externally. In addition, guises are related by standing in various sameness relations, only one of which is the familiar relation of strict identity. Since every guise enjoys bona fide ontological standing, whereas only some of these actually exist, Castañeda's ontology and semantics are Meinongian. With its intricate account of predication, guise theory affords a unified treatment of a wide range of philosophical problems concerning reference to nonexistents, negative existentials, intentional identity, referential opacity, and other matters.

Castañeda also played a pivotal role in emphasizing the significance of indexical reference. If, e.g., Paul assertively utters, 'I prefer Chardonnay', it would obviously be incorrect for Bob to report, 'Paul says that I prefer Chardonnay', since the last statement expresses the speaker's (Bob's) reference, not Paul's. At the same time, Castañeda contends, it is likewise incorrect for Bob to report Paul's saying as either 'Paul says that Paul prefers Chardonnay' or 'Paul says that Al's luncheon guest prefers Chardonnay' (when Paul *is* Al's only luncheon guest), since each of these fails to represent the essentially indexical element of Paul's assertion. Instead, Bob may correctly report, 'Paul says that he himself prefers Chardonnay', where 'he himself' is a quasi-indicator, serving to depict Paul's reference to himself *qua* self. For Castañeda (and others), quasi-indicators are a person's irreducible, essential means for describing the thoughts and experiences of others. A complete account of his view of indexicals, together with a full articulation of guise theory and his unorthodox theories of definite descriptions and proper names, is contained in *Thinking, Language, and Experience* (1989).

Castañeda's main views on practical reason and deontic logic turn on his fundamental practition-proposition distinction. A number of valuable essays on these views, together with his important replies, are collected in James E. Tomberlin, ed., *Agent, Language, and the Structure of the World* (1983), and Tomberlin, ed., *Hector-Neri Castañeda* (1986). The latter also includes Castañeda's revealing intellectual autobiography.

See also DEONTIC LOGIC, GUISE THEORY, MEINONG, PRACTICAL REASONING, PRACTITION, QUASI-INDICATOR. J.E.T.

casuistry, the case-analysis approach to the interpretation of general moral rules. Casuistry starts with paradigm cases of how and when a given general moral rule should be applied, and then reasons by analogy to cases in which the proper application of the rule is less obvious – e.g., a case in which lying is the only way for a priest not to betray a secret revealed in confession. The point of considering the series of cases is to ascertain the morally relevant similarities and differences between cases. Casuistry's heyday was the first half of the seventeenth century. Reacting against casuistry's popularity with the Jesuits and against its tendency to qualify general moral rules, Pascal penned a polemic against casuistry from which the term never recovered (see his *Provincial Letters*, 1656). But the kind of reasoning to which the term refers is flourishing in contemporary practical ethics. B.W.H.

categorical theory, a theory all of whose models are isomorphic. Because of its weak expressive power, in first-order logic with identity only theories with a finite model can be categorical; without identity no theories are categorical. A more interesting property, therefore, is being categorical in power: a theory is categorical in power α when the theory has, up to isomorphism, only one model with a domain of cardinality α. Categoricity in power shows the capacity to characterize a structure completely, only limited by cardinality. For example, the first-order theory of dense order without endpoints is categorical in power ω, the cardinality of the natural numbers. The first-order theory of simple discrete orderings with initial element, the ordering of the natural numbers, is not categorical in power ω. There are countable discrete orders, not isomorphic to the natural numbers, that are elementary equivalent to it, i.e. have the same elementary, first-order theory. In first-order logic categorical theories are complete. This is not necessarily true for extensions of first-order logic for which no completeness theorem holds. In such a logic a set of axioms may be categorical without providing an informative characterization of the theory of its unique model. The term 'elementary equivalence' was introduced around 1936 by Tarski for the property of being indistinguishable by elementary means. According to Oswald Veblen, who first used the term 'categorical' in 1904, in a discussion of the foundations of geometry, that term was suggested to him by the American pragmatist John Dewey. **See also** COMPLETENESS, MODEL THEORY. Z.G.S.

categoricity, the semantic property belonging to a set of sentences, a "postulate set," that implicitly defines (completely describes, or characterizes up to isomorphism) the structure of its intended interpretation or *standard model*. The best-known categorical set of sentences is the postulate set for number theory attributed to Peano, which completely characterizes the structure of an arithmetic progression. This structure is exemplified by the system of natural numbers with zero as distinguished element and successor (addition of 1) as distinguished function. Other exemplifications of this structure are obtained by taking as distinguished element an arbitrary integer, taking as distinguished function the process of adding an arbitrary positive or negative integer and taking as universe of discourse (or domain) the result of repeated application of the distinguished function to the distinguished element (see, e.g., Russell's *Introduction to the Mathematical Philosophy*, 1918).

More precisely, a postulate set is defined to be *categorical* if every two of its models (satisfying interpretations or realizations) are isomorphic (to each other), where, of course, two interpretations are *isomorphic* if between their respective universes of discourse there exists a one-to-one correspondence by which the distinguished elements, functions, relations, etc., of the one are mapped exactly onto those of the other. The importance of the analytic geometry of Descartes involves the fact that the system of points of a geometrical line with the "left-of relation" distinguished is isomorphic to the system of real numbers with the "less-than" relation distinguished. Categoricity, the ideal limit of success for the axiomatic method considered as a method for characterizing subject matter rather than for reorganizing a science, is known to be impossible with respect to certain subject matters using certain formal languages. The concept of categoricity can be traced back at least as far as Dedekind; the word is due to Dewey.

categories, table of. See KANT.

categories of the understanding. See KANT.

category, an ultimate class. Categories are the highest genera of entities in the world. They may contain species but are not themselves species of any higher genera. Aristotle, the first philosopher to discuss categories systematically, listed ten, including substance, quality, quantity, relation, place, and time. If a set of categories is complete, then each entity in the world will belong to a category and no entity will belong to more than one category. A prominent example of a set of categories is Descartes's dualistic classification of mind and matter. This example brings out clearly another feature of categories: an attribute that can belong to entities in one category cannot be an attribute of entities in any other category. Thus, entities in the category of matter have extension and color while no entity in the category of mind can have extension or color. **See also** ARISTOTLE, GENUS GENERALISSIMUM, RYLE. J.W.M.

category mistake, the placing of an entity in the wrong category. In one of Ryle's examples, to place the activity of exhibiting team spirit in the same class with the activities of pitching, batting, and catching is to make a category mistake; exhibiting team spirit is not a special function like pitching or batting but instead a way those special functions are performed. A second use of 'category mistake' is to refer to the attribution to an entity of a property which that entity cannot have (not merely does not happen to have), as in 'This memory is violet' or, to use an example from Carnap, 'Caesar is a prime number'. These two kinds of category mistake may seem different, but both involve misunderstandings of the natures of the things being talked about. It is thought that they go beyond simple error or ordinary mistakes, as when one attributes a property to a thing which that thing could have but does not have, since category mistakes involve attributions of properties (e.g., being a special function) to things (e.g., team spirit) that those things cannot have. According to Ryle, the test for category differences depends on whether replacement of one expression for another in the same sentence results in a type of unintelligibility that he calls "absurdity." **See also** ARISTOTLE, GENUS GENERALISSIMUM, RYLE. J.W.M.

category-preserving. See LOGICAL FORM.

category theory, a mathematical theory that studies the universal properties of structures via their relationships with one another. A category C consists of two collections Ob_C and Mor_C, the *objects* and the *morphisms* of C, satisfying the following conditions: (i) for each pair (a, b) of objects there is associated a collection $Mor_C(a, b)$ of morphisms such that each member of Mor_C belongs to one of these collections; (ii) for each object a of Ob_C there is a morphism id_a, called the *identity* on a; (iii) a composition law associating with each morphism $f: a \rightarrow b$ and each morphism $g: b \rightarrow c$ a morphism $gf: a \rightarrow c$, called the *composite* of f and g; (iv) for morphisms $f: a \rightarrow b$, $g: b \rightarrow c$, and $h: c \rightarrow d$, the equation $h(gf) = (hg)f$ holds; (v) for any morphism $f: a \rightarrow b$, we have $id_b f = f$ and $f id_a = f$. Sets with specific structures together with a collection of mappings preserving these structures are categories. Examples: (1) sets with functions between them; (2) groups with group homomorphisms; (3) topological spaces with continuous functions; (4) sets with surjections instead of arbitrary maps constitute a different category. But a category need not be composed of sets and set-theoretical maps. Examples: (5) a collection of propositions linked by the relation of logical entailment is a category and so is any preordered set; (6) a monoid taken as the unique object and its elements as the morphisms is a category. The properties of an object of a category are determined by the morphisms that are coming out of and going into this object. Objects with a universal property occupy a key position. Thus, a terminal object a is characterized by the following universal property: for any object b there is a unique morphism from b to a. A singleton set is a terminal object in the category of sets. The Cartesian product of sets, the product of groups, and the conjunction of propositions are all terminal objects in appropriate categories. Thus category theory unifies concepts and sheds a new light on the notion of universality. **See also** PHILOSOPHY OF MATHEMATICS. J.-P.M.

causal law, a statement describing a regular and invariant connection between types of events or states, where the connections involved are causal in some sense. When one speaks of causal laws as distinguished from laws that are not causal, the intended distinction may vary. Sometimes, a law is said to be causal if it relates events or states occurring at successive times, also called a *law of succession:* e.g., 'Ingestion of strychnine leads to death.' A causal law in this sense contrasts with a *law of coexistence*, which connects events or states occurring at the same time (e.g., the Wiedemann-Franz law relating thermal and electric conductivity in metals).

One important kind of causal law is the *deterministic law*. Causal laws of this kind state exceptionless connections between events, while probabilistic or statistical laws specify probability relationships between events. For any system governed by a set of deterministic laws, given the state of a system at a time, as characterized by a set of state variables, these laws will yield a unique state of the system for any later time (or, perhaps, at any time, earlier or later). Probabilistic laws will yield, for a given antecedent state of a system, only a probability value for the occurrence of a certain state at a later time. The laws of classical mechanics are often thought to be paradigmatic examples of causal laws in this sense, whereas the laws of quantum mechanics are claimed to be essentially probabilistic.

Causal laws are sometimes taken to be laws that explicitly specify certain events as causes of certain other events. Simple laws of this kind will have the form 'Events of kind *F* cause events of kind *G*'; e.g., 'Heating causes metals to expand'. A weaker related concept is this: a causal law is one that states a regularity between events which in fact are related as cause to effect, although the statement of the law itself does not say so (laws of motion expressed by differential equations are perhaps causal laws in this sense). These senses of 'causal law' presuppose a prior concept of causation.

Finally, causal laws may be contrasted with *teleological laws*, laws that supposedly describe how certain systems, in particular biological organisms, behave so as to achieve certain "goals" or "end states." Such laws are sometimes claimed to embody the idea that a future state that does not as yet exist can exert an influence on the present behavior of a system. Just what form such laws take and exactly how they differ from ordinary laws have not been made wholly clear, however.

causal theory of proper names, the view that proper names designate what they name by virtue of a kind of causal connection to it. This view is a special case, and in some instances an unwarranted interpretation, of a *direct reference view* of names. On this approach, proper names, e.g. 'Machiavelli', are, as J. S. Mill wrote, "purely denotative . . . they denote the individuals who are called by them; but they do not indicate or imply any attributes as belonging to those individuals" (*A System of Logic*, 1879). Proper names may *suggest* certain properties to many competent speakers, but any such associated information is no part of the definition of the name. Names, on this view, have no definitions. What connects a name to what it names is not the latter's satisfying some condition specified in the name's definition. Names, instead, are simply attached to things, applied as labels, as it were. A proper name, once attached, becomes a socially available device for making the relevant name bearer a subject of discourse.

On the other leading view, the *descriptivist view*, a proper name is associated with something like a definition. 'Aristotle', on this view, applies by definition to whoever satisfies the relevant properties – e.g., is 'the teacher of Alexander the Great, who wrote the *Nicomachean Ethics*'. Russell, e.g., maintained that ordinary proper names (which he contrasted with logically proper or genuine names) have definitions, that they are abbreviated definite descriptions. Frege held that names have sense, a view whose proper interpretation remains in dispute, but is often supposed to be closely related to Russell's approach. Others, most notably Searle, have defended descendants of the descriptivist view. An important variant, sometimes attributed to Frege, denies that names have articulable definitions, but nevertheless associates them with senses. And the bearer will still be, by definition (as it were), the unique thing to satisfy the relevant mode of presentation.

The direct reference approach is sometimes misleadingly called the causal theory of names. But the key idea need have nothing to do with causation: a proper name functions as a tag or label for its bearer, not as a surrogate for a descriptive expression. Whence the (allegedly) misleading term 'causal theory of names'?

Contemporary defenders of Mill's conception like Keith Donnellan and Kripke felt the need to expand upon Mill's brief remarks. What connects a present use of a name with a referent? Here Donnellan and Kripke introduce the notion of a "historical chain of communication." As Kripke tells the story a baby is baptized with a proper name. The name is used, first by those present at the baptism, subsequently by those who pick up the name in conversation, reading, and so on. The name is thus propagated, spread by usage "from link to link as if by a chain" (*Naming and Necessity*, 1980). There emerges a historical chain of uses of the name that, according to Donnellan and Kripke, bridges the gap between a present use of the name and the individual so named.

This "historical chain of communication" is occasionally referred to as a "casual chain of communication." The idea is that one's use of the name can be thought of as a causal factor in one's listener's ability to use the name to refer to the same individual. However, although Kripke in *Naming and Necessity* does occasionally refer to the chain of communication as *causal*, he more often simply speaks of the chain of communication, or of the fact that the name has been passed "by tradition from link to link." The causal aspect is not one that Kripke underscores. In more recent writings on the topic, as well as in lectures, Kripke never mentions causation in this connection, and Donnellan questions whether the chain of communication should be thought of as a causal chain.

This is not to suggest that there is no view properly called a "causal theory of names." There is such a view, but it is not the view of Kripke and Donnellan. The causal theory of names is a view propounded by physicalistically minded philosophers who desire to "reduce" the notion of "reference" to something more physicalistically acceptable, such as the notion of a causal chain running from "baptism" to later use. This is a view whose motivation is explicitly rejected by Kripke, and should be sharply distinguished from the more popular anti-Fregean approach sketched above.

H.W.

causal theory of reference. See PHILOSOPHY OF LANGUAGE.

causa sui (Latin, 'cause of itself'), an expression applied to God to mean in part that God owes his existence to nothing other than himself. It does not mean that God somehow brought himself into existence. The idea is that the very nature of God logically requires that he exists. What accounts for the existence of a being that is *causa sui* is its own nature. **See also** PHILOSOPHY OF RELIGION.

W.L.R.

causation, the relation between cause and effect, or the act of bringing about an effect, which may be an event, a state, or an object (say, a statue). The concept of causation has long been recognized as one of fundamental philosophical importance. Hume called it "the cement of the universe": causation is the relation that connects events and objects of this world in significant relationships. The concept of causation seems pervasively present in human discourse. It is expressed by not only 'cause' and its cognates but by countless other terms, such as 'produce', 'bring about', 'issue', 'generate', 'result', 'effect', and 'determine'. Moreover, many common transitive verbs ('causatives'), such as 'kill', 'break', and 'move', tacitly contain causal relations (e.g., killing involves causing to die). The concept of action, or doing, involves the idea that the agent (intentionally) causes a change in some object or other; similarly, the concept of perception involves the idea that the object perceived causes in the perceiver an appropriate perceptual experience. The physical concept of force, too, appears to involve causation as an essential ingredient: force is the causal agent of changes in motion. Further, causation is intimately related to *explanation:* to ask for an explanation of an event is, often, to ask for its cause. It is sometimes thought that our ability to make predictions, and inductive inference in general, depends on our knowledge of causal connections (or the assumption that such connections are present): the knowledge that water quenches thirst warrants the predictive inference from 'X is swallowing water' to 'X's thirst will be quenched'. More generally, the identification and systematic description of causal relations that hold in the natural world have been claimed to be the preeminent aim of science. Finally, causal concepts play a crucial role in moral and legal reasoning – e.g., in the assessment of responsibilities and liabilities.

Event causation is the causation of one event by another. A sequence of causally connected events is called a causal chain. *Agent causation* refers to the act of an agent (person, object) in bringing about a change; thus, my opening the window (i.e., my causing the window to open) is an instance of agent causation. There is a controversy as to whether agent causation is reducible to event causation. My opening the window seems reducible to event causation since in reality a certain motion of my arms, an event, causes the window to open. Some philosophers, however, have claimed that not all cases of agent causation are so reducible. *Substantival causation* is the creation of a genuinely new substance, or object, as opposed to changes in preexisting substances or a mere rearrangement of them. The possibility of substantival causation, at least in the natural world, has been disputed by some philosophers. Event causation, however, has been the primary focus of philosophical discussion in the modern and contemporary period.

The analysis of event causation has been controversial. The following four approaches have been prominent: the regularity analysis, the counterfactual analysis, the manipulation analysis, and the probabilistic analysis. The heart of the *regularity* (or *nomological*) *analysis*, associated with Hume and J. S. Mill, is the idea that causally connected events must instantiate a general regularity between like kinds of events. More precisely: if *c* is a cause of *e*, there must be types or kinds of events, *F* and *G*, such that *c* is of kind *F, e* is of kind *G*, and events of kind *F* are regularly followed by events of kind *G*. Some take the regularity involved to be merely de facto "constant conjunction" of the two event types involved; a more popular view is that the regularity must hold as a matter of "nomological necessity" – i.e., it must be a "law." An even stronger view is that the regularity must represent a causal law. A law that does this job of subsuming causally connected events is called a "covering" or "subsumptive" law, and versions of the regularity analysis that call for such laws are often referred to as the "covering-law" or "nomic-subsumptive" model of causality.

The regularity analysis appears to give a satisfactory account of some aspects of our causal concepts: e.g., causal claims are often tested by re-creating the event or situation claimed to be a cause and then observing whether a similar effect occurs. In other respects, however, the regularity account does not seem to fare so well: e.g., it has difficulty explaining the apparent fact that we can have knowledge of causal relations without knowledge of general laws. It seems possible to know, for instance, that someone's contraction of the flu was caused by her exposure to a patient with the disease, although we know of no regularity between such exposures and contraction of the disease (it may well be that only a very small fraction of persons who have been exposed to flu patients contract the disease). Do I need to know general regularities about itchings and scratchings to know that the itchy sensation on my left elbow caused me to scratch it? Further, not all regularities seem to represent causal connections (e.g., Reid's example of the succession of day and night; two successive symptoms of a disease). Distinguishing causal from non-causal regularities is one of the main problems confronting the regularity theorist.

According to the *counterfactual analysis*, what makes an event a cause of another is the fact that if the cause event had not occurred the effect event would not have. This accords with the idea that cause is a condition that is *sine qua non* for the occurrence of the effect. The view that a cause is a necessary condition for the effect is based on a similar idea. The precise form of the counterfactual account depends on how counterfactuals are understood (e.g., if counterfactuals are explained in terms of laws, the counterfactual analysis may turn into a form of the regularity analysis).

The counterfactual approach, too, seems to encounter various difficulties. It is true that on the basis of the fact that if Larry had watered my plants, as he had promised, my plants would not have died, I could claim that Larry's not watering my plants caused them to die. But it is also true that if George Bush had watered my plants, they would not have died; but does that license the claim that Bush's not watering my plants caused them to die? Also, there appear to be many cases of dependencies expressed by counterfactuals that, however, are not cases of causal dependence: e.g., if Socrates had not died, Xanthippe would not have become a widow; if I had not raised my hand, I would not have signaled. The question, then, is whether these non-causal counterfactuals can be distinguished from causal counterfactuals without the use of causal concepts. There are also questions about how we could verify counterfactuals – in particular, whether our knowledge of causal counterfactuals is ultimately dependent on knowledge of causal laws and regularities.

Some have attempted to explain causation in terms of action, and this is the *manipulation analysis:* the cause is an event or state that we can produce at will, or otherwise manipulate, to produce a certain other event as an effect. Thus, an event is a cause of another provided that by bringing about the first event we can bring about the second. This account exploits the close connection noted earlier between the concepts of action and cause, and highlights the important role that knowledge of causal connections plays in our control of natural events. However, as an analysis of the concept of cause, it may well have things backward: the concept of action seems to be a richer and more complex concept that presupposes the concept of cause, and an analysis of cause in terms of action could be accused of circularity.

The reason we think that someone's exposure to a flu patient was the cause of her catching the disease, notwithstanding the absence of an appropriate regularity (even one of high probability), may be this: exposure to flu patients increases the probability of contracting the disease. Thus, an event, *X*, may be said to be a *probabilistic cause* of an event, *Y*, provided that the probability of the occurrence of *Y*, given that *X* has occurred, is greater than the antecedent probability of *Y*. To meet certain obvious difficulties, this rough definition must be elaborated (e.g., to eliminate the possibility that *X* and *Y* are collateral effects of a common cause). There is also the question whether probabilistic causation is to be taken as an analysis of the general concept of causation, or as a special kind of causal relation, or perhaps only as evidence indicating the presence of a causal relationship. Probabilistic causation has of late been receiving increasing attention from philosophers.

When an effect is brought about by two independent causes either of which alone would have sufficed, one speaks of *causal overdetermination*. Thus, a house fire might have been caused by both a short circuit and a simultaneous lightning strike; either event alone would have caused the fire, and the fire, therefore, was causally overdetermined. Whether there are actual instances of overdetermination has been questioned; one could argue that the fire that would have been caused by the short circuit alone would not have been the same fire, and similarly for the fire that would have been caused by the lightning alone.

The steady buildup of pressure in a boiler would have caused it to explode but for the fact that a bomb was detonated seconds before, leading to a similar effect. In such a case, one speaks of *preemptive*, or *superseding, cause*. We are apt to speak of causes in regard to changes; however, "unchanges," e.g. this table's standing here through some period of time, can also have causes: the table continues to stand here because it is supported by a rigid floor. The presence of the floor, therefore, can be called a *sustaining cause* of the table's continuing to stand.

A cause is usually thought to precede its effect in time; however, some have argued that we must allow for the possibility of a cause that is temporally posterior to its effect – *backward causation* (sometimes called *retrocausation*). And there is no universal agreement as to whether a cause can be simultaneous with its effect – *concurrent causation*. Nor is there a general agreement as to whether cause and effect must, as a matter of conceptual necessity, be "contiguous" in time and space, either directly or through a causal chain of contiguous events – *contiguous causation*.

The attempt to "analyze" causation seems to have reached an impasse; the proposals on hand seem so widely divergent that one wonders whether they are all analyses of one and the same concept. But each of them seems to address some important aspect of the variegated notion that we express by the term 'cause', and it may be doubted whether there is a unitary concept of causation that can be captured in an enlightening philosophical analysis. On the other hand, the centrality of the concept, both to ordinary practical discourse and to the scientific description of the world, is difficult to deny. This has encouraged some philosophers to view causation as a primitive, one that cannot be further analyzed. There are others who advocate the extreme view (causal nihilism) that causal concepts play no role whatever in the advanced sciences, such as fundamental physical theories of space-time and matter, and that the very notion of cause is an anthropocentric projection deriving from our confused ideas of action and power.

Cavell, Stanley Louis (b.1926), American philosopher whose work has explored skepticism and its consequences. He was Walter M. Cabot Professor of Aesthetics and General Value Theory at Harvard from 1963 until 1997. Central to Cavell's thought is the view that skepticism is not a theoretical position to be refuted by philosophical theory or dismissed as a mere misuse of ordinary language; it is a reflection of the fundamental limits of human knowledge of the self, of others, and of the external world.

Cavell's work defends J. L. Austin from both positivism and deconstructionism (*Must We Mean What We Say?* 1969; *The Pitch of Philosophy*, 1994), but not because Cavell is an "ordinary language" philosopher. Rather, his defense of Austin has combined with his response to skepticism to make him a philosopher of the ordinary: he explores the conditions of the possibility and limits of ordinary language, ordinary knowledge, ordinary action, and ordinary human relationships. He uses both the resources of ordinary language and the discourse of philosophers, such as Wittgenstein, Heidegger, Thoreau, and Emerson, and of the arts. Cavell has explored the ineliminability of skepticism in *Must We Mean What We Say?*, notably in its essay on *King Lear*, and has developed his analysis in his 1979 magnum opus, *The Claim of Reason*. He has examined the benefits of acknowledging the limits of human self-understanding, and the costs of refusing to do so, in a broad range of contexts from film (*The World Viewed*, 1971; *Pursuits of Happiness*, 1981; *Contesting Tears*, 1996) to American philosophy (*The Senses of Walden*, 1972; the chapters on Emerson in *This New Yet Unapproachable America*, 1989, and *Conditions Handsome and Unhandsome*, 1990).

The Claim of Reason develops Cavell's approach by looking at Wittgenstein's notion of criteria. Criteria are not rules for the use of our words that can guarantee the correctness of the claims we make by them; rather, criteria bring out what we claim by using the words we do. More generally, in making claims to knowledge, undertaking actions, and forming interpersonal relationships, we always risk failure, but it is also precisely in that room for risk that we find the possibility of freedom. This argument is indebted not only to Wittgenstein but also to Kant, especially in the *Critique of Judgment*.

Cavell has used his view as a key to understanding classics of the theater and film. Regarding such tragic figures as Lear, he argues that their tragedies result from their refusal to accept the limits of human knowledge and human love, and their insistence on an illusory absolute and pure love. *The World Viewed* argues for a realistic approach to film, meaning that we should acknowledge that our cognitive and emotional responses to films are responses to the realities of the human condition they portray. This "ontology of film" prepared the way for Cavell's treatment of the genre of comedies of remarriage in *Pursuits of Happiness*. It also grounds his treatment of melodrama in *Contesting Tears*, which argues that human beings must remain tragically unknown to each other if we do not acknowledge the limits to our knowledge of each other.

In *The Claim of Reason* and later works Cavell has also contributed to moral philosophy by his defense – against Rawls's critique of "moral perfectionism" – of "Emersonian perfectionism": the view that no general principles of conduct can ever be employed in practice without the ongoing but never completed perfection of knowledge of oneself and of the others on and with whom one acts. Cavell's Emersonian perfectionism is thus another application of his Wittgensteinian and Kantian recognition that rules must always be supplemented by the capacity for judgment.

Cavendish, Margaret, Duchess of Newcastle (1623–73), English author of some dozen works in a variety of forms. Her central philosophical interest was the developments in natural science of her day. Her earliest works endorsed a kind of atomism, but her settled view, in *Philosophical Letters* (1664), *Observations upon Experimental Philosophy* (1666), and *Grounds of Natural Philosophy* (1668), was a kind of organic materialism. Cavendish argues for a hierarchy of increasingly fine matter, capable of self-motion. *Philosophical Letters*, among other matters, raises problems for the notion of inert matter found in Descartes, and *Observations upon Experimental Philosophy* criticizes microscopists such as Hooke for committing a double error, first of preferring the distortions introduced by instruments to unaided vision and second of preferring sense to reason. **See also** ORGANISM. M.At.

cellular automaton. See SELF-REPRODUCING AUTOMATON.

Celsus (late second century A.D.?), anti-Christian writer known only as the author of a work called *The True Doctrine* (*Alethēs Logos*), which is quoted extensively by Origen of Alexandria in his response, *Against Celsus* (written in the late 240s). *The True Doctrine* is important mainly because it is the first anti-Christian polemic of which we have significant knowledge. Origen considers Celsus to be an Epicurean, but he is uncertain about this. There are no traces of Epicureanism in Origen's quotations from Celsus, which indicate instead that he is an eclectic Middle Platonist of no great originality, a polytheist whose conception of the "unnameable" first deity transcending being and knowable only by "synthesis, analysis, or analogy" is based on Plato's description of the Good in *Republic* VI. In accordance with the *Timaeus*, Celsus believes that God created "immortal things" and turned the creation of "mortal things" over to them. According to him, the universe has a providential organization in which humans hold no special place, and its history is one of eternally repeating sequences of events separated by catastrophes. **See also** MIDDLE PLATONISM, ORIGEN. I.M.

central state materialism. See PHILOSOPHY OF MIND.

certainty, the property of being certain, which is either a psychological property of persons or an epistemic feature of proposition-like objects (e.g., beliefs, utterances, statements). We can say that a person, S, is *psychologically certain* that *p* (where '*p*' stands for a proposition) provided S has no doubt whatsoever that *p* is true. Thus, a person can be certain regardless of the degree of epistemic warrant for a proposition. In general, philosophers have not found this an interesting property to explore. The exception is Peter Unger, who argued for skepticism, claiming that (1) psychological certainty is required for knowledge and (2) no person is ever certain of anything or hardly anything. As applied to propositions, 'certain' has no univocal use. For example, some authors (e.g., Chisholm) may hold that a proposition is *epistemically certain* provided no proposition is more warranted than it. Given that account, it is possible that a proposition is certain, yet there are legitimate reasons for doubting it just as long as there are equally good grounds for doubting every equally warranted proposition. Other philosophers have adopted a Cartesian account of certainty in which a proposition is epistemically certain provided it is warranted and there are no legitimate grounds whatsoever for doubting it.

Both Chisholm's and the Cartesian characterizations of epistemic certainty can be employed to provide a basis for skepticism. If knowledge entails certainty, then it can be argued that very little, if anything, is known. For, the argument continues, only tautologies or propositions like 'I exist' or 'I have beliefs' are such that either nothing is more warranted or there are absolutely no grounds for doubt. Thus, hardly anything is known. Most philosophers have responded either by denying that 'certainty' is an absolute term, i.e. admitting of no degrees, or by denying that knowledge requires certainty (Dewey, Chisholm, Wittgenstein, and Lehrer). Others have agreed that knowledge does entail absolute certainty, but have argued that absolute certainty is possible (e.g., Moore).

Sometimes 'certain' is modified by other expressions, as in 'morally certain' or 'metaphysically certain' or 'logically certain'. Once again, there is no universally accepted account of these terms. Typically, however, they are used to indicate degrees of warrant for a proposition, and often that degree of warrant is taken to be a function of the *type* of proposition under consideration. For example, the proposition that smoking causes cancer is *morally certain* provided its warrant is sufficient to justify acting as though it were true. The evidence for such a proposition may, of necessity, depend upon recognizing particular features of the world. On the other hand, in order for a proposition, say that every event has a cause, to be *metaphysically certain*, the evidence for it must not depend upon recognizing particular features of the world but rather upon recognizing what must be true in order for our world to be the kind of world it is – i.e., one having causal connections. Finally, a proposition, say that every effect has a cause, may be *logically certain* if it is derivable from "truths of logic" that do not depend in any way upon recognizing anything about our world. Since other taxonomies for these terms are employed by philosophers, it is crucial to examine the use of the terms in their contexts.

character, the comprehensive set of ethical and intellectual dispositions of a person. Intellectual virtues – like carefulness in the evaluation of evidence – promote, for one, the practice of seeking truth. Moral or ethical virtues – including traits like courage and generosity – dispose persons not only to choices and actions but also to attitudes and emotions. Such dispositions are generally considered relatively stable and responsive to reasons.

Appraisal of character transcends direct evaluation of particular actions in favor of examination of some set of virtues or the admirable human life as a whole. On some views this admirable life grounds the goodness of particular actions. This suggests seeking guidance from role models, and their practices, rather than relying exclusively on rules. Role models will, at times, simply perceive the salient features of a situation and act accordingly. Being guided by role models requires some recognition of just who should be a role model. One may act out of character, since dispositions do not automatically produce particular actions in specific cases. One may also have a conflicted character if the virtues one's character comprises contain internal tensions (between, say, tendencies to impartiality and to friendship). The importance of formative education to the building of character introduces some good fortune into the acquisition of character. One can have a good character with a disagreeable personality or have a fine personality with a bad character because personality is not typically a normative notion, whereas character is. **See also** CARDINAL VIRTUES, ETHICS, PERSONAL IDENTITY, EPISTEMOLOGY, VIRTUE ETHICS. Charron, Pierre (1541–1603), French Catholic theologian who became the principal expositor of Montaigne's ideas, presenting them in didactic form. His first work, *The Three Truths* (1595), presented a negative argument for Catholicism by offering a skeptical challenge to atheism, non-Christian religions, and Calvinism. He argued that we cannot know or understand God because of his infinitude and the weakness of our faculties. We can have no good reasons for rejecting Christianity or Catholicism. Therefore, we should accept it on faith alone. His second work, *On Wisdom* (1603), is a systematic presentation of Pyrrhonian skepticism coupled with a fideistic defense of Catholicism. The skepticism of Montaigne and the Greek Skeptics is used to show that we cannot know anything unless God reveals it to us. This is followed by offering an ethics to live by, an undogmatic version of Stoicism. This is the first modern presentation of a morality apart from any religious considerations. Charron's *On Wisdom* was extremely popular in France and England. It was read and used by many philosophers and theologians during the seventeenth century. Some claimed that his skepticism opened his defense of Catholicism to question, and suggested that he was insincere in his fideism. He was defended by important figures in the French Catholic Church. **See also** MONTAIGNE. R.H.P.

cheapest-cost avoider, in the economic analysis of law, the party in a dispute that could have prevented the dispute, or minimized the losses arising from it, with the lowest loss to itself. The term encompasses several types of behavior. As the lowest-cost accident avoider, it is the party that could have prevented the accident at the lowest cost. As the lowest-cost insurer, it is the party that could been have insured against the losses arising from the dispute. This could be the party that could have purchased insurance at the lowest cost or self-insured, or the party best able to appraise the expected losses and the probability of the occurrence. As the lowest-cost briber, it is the party least subject to transaction costs. This party is the one best able to correct any legal errors in the assignment of the entitlement by purchasing the entitlement from the other party. As the lowest-cost information gatherer, it is the party best able to make an informed judgment as to the likely benefits and costs of an action. **See also** COASE THEOREM, PHILOSOPHY OF ECONOMICS. M.S.M.

***cheng* (*ch'eng*)** (Chinese, 'sincerity'). It means much more than just a psychological attitude. Mencius barely touched upon the subject; it was in the Confucian *Doctrine of the Mean* that the idea was greatly elaborated. The ultimate metaphysical principle is characterized by *cheng*, as it is true, real, totally beyond illusion and delusion. According to the classic, sincerity is the Way of Heaven; to think how to be sincere is the Way of man; and only those who can be absolutely sincere can fully develop their nature, after which they can assist in the transforming and nourishing process of Heaven and Earth. **See also** MENCIUS. S.-h.L.

Cheng Hao (Ch'eng Hao) (1032–85), Cheng Yi (Ch'eng Yi) (1033–1107), Chinese philosophers, brothers who established mature Neo-Confucianism. They elevated the notion of *li* (pattern) to preeminence and systematically linked their metaphysics to central ethical notions, e.g. *xing* (nature) and *xin* (heart/mind).

Cheng Hao was more mystical and a stronger intuitionist. He emphasized a universal, creative spirit of life, *ren* (benevolence), which permeates all things, just as *qi* (ether/vital force) permeates one's body, and likened an "unfeeling" (i.e., unbenevolent) person to an "unfeeling" (i.e., paralyzed) person. Both fail to realize a unifying "oneness." Cheng Yi presented a more detailed and developed philosophical system in which the *li* (pattern) in the mind was awakened by perceiving the *li* in the world, particularly as revealed in the classics, and by *tui* (extending/inferring) their interconnections. If one studies with *jing* (reverential attentiveness), one can gain both cognitively accurate and affectively appropriate "real knowledge," which Cheng Yi illustrates with an allegory about those who "know" (i.e., have heard that) tigers are dangerous and those who "know" because they have been mauled.

The two brothers differ most in their views on self-cultivation. For Cheng Hao, it is more an inner affair: setting oneself right by bringing into full play one's moral intuition. For Cheng Yi, self-cultivation was more external: *zhi zhi* (extending knowledge) through *ge wu* (investigating things). Here lie the beginnings of the major schools of Neo-Confucianism: the Lu-Wang and Cheng-Zhu schools. **See also** LI^1, NEO-CONFUCIANISM. P.J.I.

Chen Xianzheng (Ch'en Hsien-chang) (1428–1500), Chinese poet-philosopher. In the early Ming dynasty, Zhu Xi's *lixue* (learning of principles) had been firmly established as the orthodoxy and became somewhat fossilized. Chen opposed this trend and emphasized "self-attained learning" by digging deep into the self to find meaning in life. He did not care for book learning and conceptualization, and chose to express his ideas and feelings through poems. Primarily a Confucian, he also drew from Buddhism and Daoism. He was credited with being the first to realize the depth and subtlety of *xinxue* (learning of the mind), later developed into a comprehensive philosophy by Wang Yangming. **See also** NEO-CONFUCIANISM, WANG YANGMING, ZHU XI. Chinese Legalism, the collective views of the Chinese "school of laws" theorists, so called in recognition of the importance given to strict application of laws in the work of Shang Yang (390–338 B.C.) and his most prominent successor, Hanfeizi (d.223 B.C.). The Legalists were political realists who believed that success in the context of Warring States China (403–221 B.C.) depended on organizing the state into a military camp, and that failure meant nothing less than political extinction. Although they challenged the viability of the Confucian model of ritually constituted community with their call to law and order, they sidestepped the need to dispute the ritual-versus-law positions by claiming that different periods had different problems, and different problems required new and innovative solutions.

Shang Yang believed that the fundamental and complementary occupations of the state, agriculture and warfare, could be prosecuted most successfully by insisting on adherence to clearly articulated laws and by enforcing strict punishments for even minor violations. There was an assumed antagonism between the interests of the individual and the interests of the state. By manipulating rewards and punishments and controlling the "handles of life and death," the ruler could subjugate his people and bring them into compliance with the national purpose. Law would replace morality and function as the exclusive standard of good. Fastidious application of the law, with severe punishments for infractions, was believed to be a policy that would arrest criminality and quickly make punishment unnecessary.

Given that the law served the state as an objective and impartial standard, the goal was to minimize any reliance upon subjective interpretation. The Legalists thus conceived of the machinery of state as operating automatically on the basis of self-regulating and self-perpetuating "systems." They advocated techniques of statecraft (*shu*) such as "accountability" (*xingming*), the demand for absolute congruency between stipulated duties and actual performance in office, and "doing nothing" (*wuwei*), the ruler residing beyond the laws of the state to reformulate them when necessary, but to resist reinterpreting them to accommodate particular cases.

Han Feizi, the last and most influential spokesperson of Legalism, adapted the military precept of strategic advantage (*shi*) to the rule of government. The ruler, without the prestige and influence of his position, was most often a rather ordinary person. He had a choice: he could rely on his personal attributes and pit his character against the collective strength of his people, or he could tap the collective strength of the empire by using his position and his exclusive power over life and death as a fulcrum to ensure that his will was carried out. What was strategic advantage in warfare became political purchase in the government of the state. Only the ruler with the astuteness and the resolve to hoard and maximize all of the advantages available to him could guarantee continuation in power. Hanfei believed that the closer one was to the seat of power, the greater threat one posed to the ruler. Hence, all nobler virtues and sentiments – benevolence, trust, honor, mercy – were repudiated as means for conspiring ministers and would-be usurpers to undermine the absolute authority of the throne. Survival was dependent upon total and unflagging distrust.

Chinese philosophy, philosophy produced in China from the sixth century B.C. to the present.

Traditional Chinese philosophy. Its history may be divided into six periods:

(1) Pre-Qin, before 221 B.C.
  Spring and Autumn, 722–481 B.C.
  Warring States, 403–222 B.C.
(2) Han, 206 B.C.–A.D. 220
  Western (Former) Han, 206 B.C.–A.D. 8
  Xin, A.D. 9–23
  Eastern (Later) Han, A.D. 25–220
(3) Wei-Jin, 220–420
  Wei, 220–65
  Western Jin, 265–317
  Eastern Jin, 317–420
(4) Sui-Tang, 581–907
  Sui, 581–618
  Tang, 618–907
  Five Dynasties, 907–60
(5) Song-(Yuan)-Ming, 960–1644
  Northern Song, 960–1126
  Southern Song, 1127–1279
  Yuan (Mongol), 1271–1368
  Ming, 1368–1644
(6) Qing (Manchu), 1644–1912

In the late Zhou dynasty (1111–249 B.C.), before Qin (221–206 B.C.) unified the country, China entered the so-called Spring and Autumn period and the Warring States period, and Zhou culture was in decline. The so-called hundred schools of thought were contending with one another; among them six were philosophically significant:

(a) *Rujia* (Confucianism), represented by Confucius (551–479 B.C.), Mencius (371–289 B.C.?), and Xunzi (fl. 298–238 B.C.)

(b) *Daojia* (Daoism), represented by Laozi (sixth or fourth century B.C.) and Zhuangzi (between 399 and 295 B.C.)
(c) *Mojia* (Mohism), represented by Mozi (fl. 479–438 B.C.)
(d) *Mingjia* (Logicians), represented by Hui Shi (380–305 B.C.), Gongsun Long (b.380 B.C.?)
(e) *Yinyangjia* (Yin-yang school), represented by Zou Yan (305–240 B.C.?)
(f) *Fajia* (Legalism), represented by Hanfei (d.233 B.C.)

Thus, China enjoyed its first golden period of philosophy in the Pre-Qin period. As most Chinese philosophies were giving responses to existential problems then, it is no wonder Chinese philosophy had a predominantly practical character. It has never developed the purely theoretical attitude characteristic of Greek philosophy.

During the Han dynasty, in 136 B.C., Confucianism was established as the state ideology. But it was blended with ideas of Daoism, Legalism, and the Yin-yang school. An organic view of the universe was developed; creative thinking was replaced by study of the so-called Five Classics: *Book of Poetry, Book of History, Book of Changes, Book of Rites*, and *Spring and Autumn Annals*. As the first emperor of Qin burned the classics except for the *Yijing*, scholars were asked in the early Han to write down the texts they had memorized in modern script. Later some texts in ancient script were discovered, but were rejected as spurious by modern-script supporters. Hence there were constant disputes between the modern-script school and the ancient-script school.

Wei-Jin scholars were fed up with studies of the classics in trivial detail. They also showed a tendency to step over the bounds of rites. Their interest turned to something more metaphysical; the *Laozi*, the *Zhuangzi*, and the *Yijing* were their favorite readings. Especially influential were Xiang Xiu's (fl. A.D. 250) and Guo Xiang's (d.A.D. 312) *Commentaries* on the *Zhuangzi*, and Wang Bi's (226–49) *Commentaries* on the *Laozi* and *Yijing*. Although Wang's perspective was predominantly Daoist, he was the first to brush aside the *Xiangshu* (forms and numbers) approach to the study of the *Yijing* and concentrate on *yili* (meanings and principles) alone. Song philosophers continued the *yili* approach, but they reinterpreted the classics from a Confucian perspective.

Although Buddhism was imported into China in the late Han period, it took several hundred years for the Chinese to absorb Buddhist insights and ways of thinking. First the Chinese had to rely on *geyi* (matching the concepts) by using Daoist ideas to transmit Buddhist messages. After the Chinese learned a great deal from Buddhism by translating Buddhist texts into Chinese, they attempted to develop the Chinese versions of Buddhism in the Sui-Tang period. On the whole they favored Mahayana over Hinayana (Theravada) Buddhism, and they developed a much more life-affirming attitude through Huayan and Tiantai Buddhism, which they believed to represent Buddha's mature thought. Chan went even further, seeking sudden enlightenment instead of scripture studies. Chan, exported to Japan, has become Zen, a better-known term in the West.

In response to the Buddhist challenge, the Neo-Confucian thinkers gave a totally new interpretation of Confucian philosophy by going back to insights implicit in Confucius's so-called Four Books: the *Analects*, the *Mencius, The Great Learning*, and the *Doctrine of the Mean* (the latter two were chapters taken from the *Book of Rites*). They were also fascinated by the Yijing. They borrowed ideas from Buddhism and Daoism to develop a new Confucian cosmology and moral metaphysics. Song-Ming Neo-Confucianism brought Chinese philosophy to a new height; some consider the period the Chinese Renaissance. The movement started with Zhou Dunyi (1017–73), but the real founders of Neo-Confucianism were the Cheng brothers: Cheng Hao (1032–85) and Cheng Yi (1033–1107). Then came Zhu Xi (1130–1200), a great synthesizer often compared to Thomas Aquinas or Kant in the West, who further developed Cheng Yi's ideas into a systematic philosophy and originated the so-called Cheng-Zhu school. But he was opposed by his younger contemporary Lu Xiangshan (1139–93). During the Ming dynasty, Wang Yangming (1472–1529) reacted against Zhu Xi by reviving the insight of Lu Xiangshan, hence the so-called Lu-Wang school.

During the Qing dynasty, under the rule of the Manchus, scholars turned to historical scholarship and showed little interest in philosophical speculation. In the late Qing, Kang Youwei (1858–1927) revived the modern-script school, pushed for radical reform, but failed miserably in his attempt.

Contemporary Chinese philosophy. Three important trends can be discerned, intertwined with one another: the importation of Western philosophy, the dominance of Marxism on Mainland China, and the development of contemporary New Confucian philosophy. During the early twentieth century China awoke to the fact that traditional Chinese culture could not provide all the means for China to enter into the modern era in competition with the Western powers. Hence the first urgent task was to learn from the West.

Almost all philosophical movements had their exponents, but they were soon totally eclipsed by Marxism, which was established as the official ideology in China after the Communist takeover in 1949. Mao Zedong (1893–1976) succeeded in the line of Marx, Engels, Lenin, and Stalin. The Communist regime was intolerant of all opposing views. The Cultural Revolution was launched in 1967, and for a whole decade China closed its doors to the outside world. Almost all the intellectuals inside or outside the Communist party were purged or suppressed. After the Cultural Revolution was over, universities were reopened in 1978. From 1979 to 1989, intellectuals enjoyed unprecedented freedom. One editorial in *People's Daily News* said that Marx's ideas were the product of the nineteenth century and did not provide all the answers for problems at the present time, and hence it was desirable to develop Marxism further. Such a message was interpreted by scholars in different ways. Although the thoughts set forth by scholars lacked depth, the lively atmosphere could be compared to the May Fourth New Culture Movement in 1919. Unfortunately, however, violent suppression of demonstrators in Peking's Tiananmen Square in 1989 put a stop to all this. Control of ideology became much stricter for the time being, although the doors to the outside world were not completely closed.

As for the Nationalist government, which had fled to Taiwan in 1949, the control of ideology under its jurisdiction was never total on the island; liberalism has been strong among the intellectuals. Analytic philosophy, existentialism, and hermeneutics all have their followers; today even radicalism has its attraction for certain young scholars.

Even though mainstream Chinese thought in the twentieth century has condemned the Chinese tradition altogether, that tradition has never completely died out. In fact the most creative talents were found in the contemporary New Confucian movement, which sought to bring about a synthesis between East and West. Among those who stayed on the mainland, Feng Youlan (1895–1990) and He Lin (1902–92) changed their earlier views after the Communist takeover, but Liang Shuming (1893–1988) and Xiong Shili (1885–1968) kept some of their beliefs. Qian Mu (1895–1990) and Tang Junyi (1909–78) moved to Hong Kong and Thomé H. Fang (1899–1976), Xu Fuguan (1903–82), and Mou Zongsan (1909–95) moved to Taiwan, where they exerted profound influence on younger scholars. Today contemporary New Confucianism is still a vital intellectual movement in Hong Kong, Taiwan, and overseas; it is even studied in Mainland China. The New Confucians urge a revival of the traditional spirit of *ren* (humanity) and *sheng* (creativity); at the same time they turn to the West, arguing for the incorporation of modern science and democracy into Chinese culture.

The New Confucian philosophical movement in the narrower sense derived inspiration from Xiong Shili. Among his disciples the most original thinker is Mou Zongsan, who has developed his own system of philosophy. He maintains that the three major Chinese traditions – Confucian, Daoist, and Buddhist – agree in asserting that humans have the endowment for intellectual intuition, meaning personal participation in *dao* (the Way). But the so-called third generation has a much broader scope; it includes scholars with varied backgrounds such as Yu Yingshi (b.1930), Liu Shuxian (b.1934), and Du Weiming (b.1940), whose ideas have an impact on intellectuals at large and whose selected writings have recently been allowed to be published on the mainland. The future of Chinese philosophy will still depend on the interactions of imported Western thought, Chinese Marxism, and New Confucianism.

ching (Chinese, 'reverence', 'seriousness', 'attentiveness', 'composure'). In early texts, *ching* is the appropriate attitude toward spirits, one's parents, and the ruler; it was originally interchangeable with another term, *kung* (respect). Among Neo-Confucians, these terms are distinguished: *ching* reserved for the inner state of mind and *kung* for its outer manifestations. This distinction was part of the Neo-Confucian response to the quietistic goal of meditative calm advocated by many Daoists and Buddhists. Neo-Confucians sought to maintain an imperturbable state of "reverential attentiveness" not only in meditation but throughout all activity. This sense of *ching* is best understood as a Neo-Confucian appropriation of the Chan (Zen) ideal of *yi-hsing sàn-mei* (universal *samādhi*), prominent in texts such as the *Platform Sutra*. P.J.I.

Chisholm, R(oderick) M(ilton) (1916–99), influential American philosopher whose publications spanned the field, including ethics and the history of philosophy. He is known mainly as an epistemologist, metaphysician, and philosopher of mind. In early opposition to powerful forms of reductionism, such as phenomenalism, extensionalism, and physicalism, Chisholm developed an original philosophy of his own. Educated at Brown and Harvard (Ph.D., 1942), he spent nearly his entire career at Brown.

He is known chiefly for the following contributions. (a) Together with his teacher and later his colleague at Brown, C. J. Ducasse, he developed and long defended an adverbial account of sensory experience, set against the sense-datum act-object account then dominant. (b) On the basis of deeply probing analysis of the free will problematic, he defended a libertarian position, again in opposition to the compatibilism long orthodox in analytic circles. His libertarianism had, moreover, an unusual account of agency, based on distinguishing transeunt (event) causation from immanent (agent) causation. (c) In opposition to the celebrated linguistic turn of linguistic philosophy, he defended the primacy of intentionality, a defense made famous not only through important papers, but also through his extensive and eventually published correspondence with Wilfrid Sellars. (d) Quick to recognize the importance and distinctiveness of the *de se*, he welcomed it as a basis for much *de re* thought. (e) His realist ontology is developed through an intentional concept of 'entailment', used to define key concepts of his system and to provide criteria of identity for occupants of fundamental categories. (f) In epistemology, he famously defended forms of foundationalism and internalism, and offered a delicately argued (dis)solution of the ancient problem of the criterion.

The principles of Chisholm's epistemology and metaphysics are not laid down antecedently as hard-and-fast axioms. Lacking any inviolable antecedent privilege, they must pass muster in the light of their consequences and by comparison with whatever else we may find plausible. In this regard he sharply contrasts with such epistemologists as Popper, with the skepticism of justification attendant on his deductivism, and Quine, whose stranded naturalism drives so much of his radical epistemology and metaphysics. By contrast, Chisholm has no antecedently set epistemic or metaphysical principles. His philosophical views develop rather dialectically, with sensitivity to whatever considerations, examples, or counterexamples reflection may reveal as relevant. This makes for a demanding complexity of elaboration, relieved, however, by a powerful drive for ontological and conceptual economy.

choice, axiom of. See LÖWENHEIM-SKOLEM THEOREM, SET THEORY.

choice sequence, a variety of infinite sequence introduced by L. E. J. Brouwer to express the non-classical properties of the continuum (the set of real numbers) within intuitionism. A choice sequence is determined by a finite initial segment together with a "rule" for continuing the sequence. The rule, however, may allow some freedom in choosing each subsequent element. Thus the sequence might start with the rational numbers 0 and then ½, and the rule might require the $n + 1$st element to be some rational number within $(½)^n$ of the nth choice, without any further restriction. The sequence of rationals thus generated must converge to a real number, r. But r's definition leaves open its exact location in the continuum. Speaking intuitionistically, r violates the classical *law of trichotomy:* given any pair of real numbers (e.g., r and ½), the first is either less than, equal to, or greater than the second.

From the 1940s Brouwer got this non-classical effect without appealing to the apparently non-mathematical notion of free choice. Instead he used sequences generated by the activity of an idealized mathematician (the creating subject), together with propositions that he took to be undecided. Given such a proposition, P – e.g., Fermat's last theorem (that for $n > 2$ there is no general method of finding triplets of numbers with the property that the sum of each of the first two raised to the nth power is equal to the result of raising the third to the nth power) or Goldbach's conjecture (that every even number is the sum of two prime numbers) – we can modify the definition of r: The $n + 1$st element is ½ if at the nth stage of research P remains undecided. That element and all its successors are $½ + (½)^n$ if by that stage P is proved; they are $½ – (½)^n$ if P is refuted. Since he held that there is an endless supply of such propositions, Brouwer believed that we can always use this method to refute classical laws.

In the early 1960s Stephen Kleene and Richard Vesley reproduced some main parts of Brouwer's theory of the continuum in a formal system based on Kleene's earlier recursion-theoretic interpretation of intuitionism and of choice sequences. At about the same time – but in a different and occasionally incompatible vein – Saul Kripke formally captured the power of Brouwer's counterexamples without recourse to recursive functions and without invoking either the creating subject or the notion of free choice. Subsequently Georg Kreisel, A. N. Troelstra, Dirk Van Dalen, and others produced formal systems that analyze Brouwer's basic assumptions about open-futured objects like choice sequences.

See also MATHEMATICAL INTUITIONISM, PHILOSOPHY OF MATHEMATICS. C.J.P.

Chomsky, Noam (b.1928), preeminent American linguist, philosopher, and political activist who has spent his professional career at the Massachusetts Institute of Technology. Chomsky's best-known scientific achievement is the establishment of a rigorous and philosophically compelling foundation for the scientific study of the grammar of natural language. With the use of tools from the study of formal languages, he gave a far more precise and explanatory account of natural language grammar than had previously been given (*Syntactic Structures*, 1957). He has since developed a number of highly influential frameworks for the study of natural language grammar (e.g., *Aspects of the Theory of Syntax*, 1965; *Lectures on Government and Binding*, 1981; *The Minimalist Program*, 1995). Though there are significant differences in detail, there are also common themes that underlie these approaches. Perhaps the most central is that there is an innate set of linguistic principles shared by all humans, and the purpose of linguistic inquiry is to describe the initial state of the language learner, and account for linguistic variation via the most general possible mechanisms.

On Chomsky's conception of linguistics, languages are structures in the brains of individual speakers, described at a certain level of abstraction within the theory. These structures occur within the language faculty, a hypothesized module of the human brain. Universal Grammar is the set of principles hard-wired into the language faculty that determine the class of possible human languages. This conception of linguistics involves several influential and controversial theses. First, the hypothesis of a Universal Grammar entails the existence of innate linguistic principles. Second, the hypothesis of a language faculty entails that our linguistic abilities, at least so far as grammar is concerned, are not a product of general reasoning processes. Finally, and perhaps most controversially, since having one of these structures is an intrinsic property of a speaker, properties of languages so conceived are determined solely by states of the speaker. On this individualistic conception of language, there is no room in scientific linguistics for the social entities determined by linguistic communities that are languages according to previous anthropological conceptions of the discipline.

Many of Chomsky's most significant contributions to philosophy, such as his influential rejection of behaviorism ("Review of Skinner's *Verbal Behavior*," *Language*, 1959), stem from his elaborations and defenses of the above consequences (cf. *Cartesian Linguistics*, 1966; *Reflections on Language*, 1975; *Rules and Representations*, 1980; *Knowledge of Language*, 1986). Chomsky's philosophical writings are characterized by an adherence to methodological naturalism, the view that the mind should be studied like any other natural phenomenon. In recent years, he has also argued that reference, in the sense in which it is used in the philosophy of language, plays no role in a scientific theory of language ("Language and Nature," *Mind*, 1995).

***ch'üan*,** Chinese term for a key Confucian concept that may be rendered as 'weighing of circumstances', 'exigency', or 'moral discretion'. A metaphorical extension of the basic sense of a steelyard for measuring weight, *ch'üan* essentially pertains to assessment of the importance of moral considerations to a current matter of concern. Alternatively, the exercise of *ch'üan* consists in a judgment of the comparative importance of competing options answering to a current problematic situation. The judgment must accord with *li* (principle, reason), i.e. be a principled or reasoned judgment. In the sense of exigency, *ch'üan* is a hard case, i.e. one falling outside the normal scope of the operation of standards of conduct. In the sense of 'moral discretion', *ch'üan* must conform to the requirement of *i* (rightness). **See also** CONFUCIANISM. A.S.C.

Church, Alonzo (1903–95), American logician, mathematician, and philosopher, known in pure logic for his discovery and application of the Church lambda operator, one of the central ideas of the Church lambda calculus, and for his rigorous formalizations of the theory of types, a higher-order underlying logic originally formulated in a flawed form by Whitehead and Russell. The lambda operator enables direct, unambiguous, symbolic representation of a range of philosophically and mathematically important expressions previously representable only ambiguously or after elaborate paraphrasing. In philosophy, Church advocated rigorous analytic methods based on symbolic logic. His philosophy was characterized by his own version of logicism, the view that mathematics is reducible to logic, and by his unhesitating acceptance of higher-order logics. Higher-order logics, including second-order, are ontologically rich systems that involve quantification of higher-order variables, variables that range over properties, relations, etc. Higher-order logics were routinely used in foundational work by Frege, Peano, Hilbert, Gödel, Tarski, and others until around World War II, when they suddenly lost favor. In regard to both his logicism and his acceptance of higher-order logics, Church countered trends, increasingly dominant in the third quarter of the twentieth century, against the reduction of mathematics to logic and against the so-called ontological excesses of higher-order logic. In the 1970s, although admired for his high standards of rigor and for his achievements, Church was regarded as conservative or perhaps even reactionary. Opinions have softened in recent years.

On the computational and epistemological sides of logic Church made two major contributions. He was the first to articulate the now widely accepted principle known as Church's thesis, that every effectively calculable arithmetic function is recursive. At first highly controversial, this principle connects intuitive, epistemic, extrinsic, and operational aspects of arithmetic with its formal, ontic, intrinsic, and abstract aspects. Church's thesis sets a purely arithmetic outer limit on what is computationally achievable. Church's further work on Hilbert's "decision problem" led to the discovery and proof of Church's theorem – basically that there is no computational procedure for determining, of a finite-premised first-order argument, whether it is valid or invalid. This result contrasts sharply with the previously known result that the computational truth-table method suffices to determine the validity of a finite-premised truth-functional argument. Church's thesis at once highlights the vast difference between propositional logic and first-order logic and sets an outer limit on what is achievable by "automated reasoning."

Church's mathematical and philosophical writings are influenced by Frege, especially by Frege's semantic distinction between sense and reference, his emphasis on purely syntactical treatment of proof, and his doctrine that sentences denote (are names of) their truth-values.

church fathers. See PATRISTIC AUTHORS.

Churchland, Patricia Smith (b.1943), Canadian-born American philosopher and advocate of neurophilosophy. Skeptical of philosophy's a priori specification of mental categories and dissatisfied with computational psychology's purely top-down approach to their function, Churchland began studying the brain at the University of Manitoba medical school. The result was a unique merger of science and philosophy, a "neurophilosophy" that challenged the prevailing methodology of mind. Thus, in a series of articles she outlined a new neurobiologically based paradigm that subsumes simple non-linguistic structures and organisms, since the brain is an evolved organ, while at the same time preserving functionalism, since a cognitive system's mental states are explained via neurofunctional theories. It is a strategy of cooperation between psychology and neuroscience eloquently described in her book *Neurophilosophy* (1986) with the prediction that genuine cognitive phenomena will be reduced, some still conceptualized within the commonsense framework, others transformed through the sciences. She extends the program by also addressing topics from the metaphysics of consciousness and free will to the connection between epilepsy and religious experience in *Brain Wise* (2002), then aims the lens of neurophilosophy at the topic of morality in *Braintrust* (2011). The same intellectual confluence of philosophy and neuroscience is displayed in Churchland's various collaborations: with psychologist and computational neurobiologist Terrence Sejnowski in *The Computational Brain* (1992); with neuroscientist Rodolfo Llinas in *The Mind-Brain Continuum* (1996); and with philosopher and husband Paul Churchland in *On the Contrary* (1998). Patricia and Paul Churchland are jointly honored and appraised in R. McCauley, *The Churchlands and Their Critics* (1996).

Churchland received her B.Phil. from Oxford in 1969 and held positions at the University of Manitoba and the Institute for Advanced Studies at Princeton, settling at the University of California, San Diego, with appointments in Philosophy, the Institute for Neural Computation, and the Salk Institute.

Churchland, Paul M. (b.1942), Canadian-born American philosopher and leading proponent of eliminative materialism. His literary corpus constitutes a lucidly written, scientifically informed narrative of neurocomputational philosophy. In his *Scientific Realism and the Plasticity of Mind* (1979), Churchland maintains that science is best construed realistically, perception is conceptually driven with no observational given, and language is holistic with meaning fixed by networks of associated usage. Moreover, higher-level scientific theories should be reduced by, incorporated into, or eliminated in favor of more basic theories from natural science. In a specific case of interest, Churchland maintains that commonsense psychology is a largely false empirical theory, to be replaced by a non-sentential, neuroscientific framework. Skepticism regarding "sentential" approaches is a common thread, present in earlier papers, and famously defended in "Eliminative Materialism and the Propositional Attitudes" (1981). The non-sentential, neuroscientific framework is embodied in connectionist network or parallel distributed processing models. With essays in *A Neurocomputational Perspective* (1989), Churchland adds that genuine psychological processes are sequences of activation patterns over neuronal networks. Scientific theories, likewise, are learned vectors in the space of possible activation patterns, with scientific explanation being prototypical activation of a preferred vector. The semantics of a theory implies that synonymy, or the sharing of concepts, is a similarity between patterns in neuronal state-space. Classical epistemology, too, should be neurocomputationally naturalized. Even moral knowledge is analyzed as stored prototypes of social reality that are elicited when an individual navigates through other neurocomputational systems. The entire picture is expressed in *The Engine of Reason, the Seat of the Soul* (1996) and, with his wife, Patricia Churchland, by the essays in *On the Contrary* (1998). He also addresses topics from morality to color perception in *Neurophilosophy at Work* (2007). What has emerged is a neurocomputational embodiment of the naturalist program, a pan-philosophy that promises to capture science, epistemology, language, and morals in one broad sweep of its connectionist net.

Churchland received his Ph.D. from the University of Pittsburgh in 1969 and held positions at the University of Toronto, the University of Manitoba, and the Institute for Advanced Studies at Princeton, settling at the University of California, San Diego, with appointments in Philosophy, Cognitive Science, and the Institute for Neural Computation.

Church's theorem. See CHURCH'S THESIS.

Church's thesis, the thesis, proposed by Alonzo Church at a meeting of the American Mathematical Society in April 1935, "that the notion of an effectively calculable function of positive integers should be identified with that of a recursive function." This proposal has been called Church's thesis ever since Kleene used that name in his *Introduction to Metamathematics* (1952). The informal notion of an effectively calculable function (effective procedure, or algorithm) had been used in mathematics and logic to indicate that a class of problems is solvable in a "mechanical fashion" by following fixed elementary rules. Underlying epistemological concerns came to the fore when modern logic moved in the late nineteenth century from axiomatic to formal presentations of theories. Hilbert suggested in 1904 that such formally presented theories be taken as objects of mathematical study, and metamathematics has been pursued vigorously and systematically since the 1920s. In its pursuit, concrete issues arose that required for their resolution a delimitation of the class of effective procedures. Hilbert's important *Entscheidungsproblem*, the decision problem for predicate logic, was one such issue. It was solved negatively by Church and Turing – relative to the precise notion of recursiveness; the result was obtained independently by Church and Turing, but is usually called *Church's theorem*. A second significant issue was the general formulation of the incompleteness theorems as applying to *all* formal theories (satisfying the usual representability and derivability conditions), not just to specific formal systems like that of *Principia Mathematica*.

According to Kleene, Church proposed in 1933 the identification of effective calculability with λ-definability. That proposal was not published at the time, but in 1934 Church mentioned it in conversation with Gödel, who judged it to be "thoroughly unsatisfactory." In his Princeton Lectures of 1934, Gödel defined the concept of a recursive function, but he was not convinced that all effectively calculable functions would fall under it. The proof of the equivalence between λ-definability and recursiveness (by Church and Kleene) led to Church's first published formulation of the thesis as quoted above. The thesis was reiterated in Church's "An Unsolvable Problem of Elementary Number Theory" (1936). Turing introduced, in "On Computable Numbers, with an Application to the *Entscheidungs* Problem" (1936), a notion of computability by machines and maintained that it captures effective calculability exactly. Post's paper "Finite Combinatory Processes, Formulation 1" (1936) contains a model of computation that is strikingly similar to Turing's. However, Post did not provide any analysis; he suggested considering the identification of effective calculability with his concept as a working hypothesis that should be verified by investigating ever wider formulations and reducing them to his basic formulation. (The classic papers of Gödel, Church, Turing, Post, and Kleene are all reprinted in Davis, ed., *The Undecidable*, 1965.)

In his 1936 paper Church gave one central reason for the proposed identification, namely that other plausible explications of the informal notion lead to mathematical concepts weaker than or equivalent to recursiveness. Two paradigmatic explications, calculability of a function via algorithms or in a logic, were considered by Church. In either case, the steps taken in determining function values have to be effective; and if the effectiveness of steps is, as Church put it, interpreted to mean recursiveness, then the function is recursive. The fundamental interpretative difficulty in Church's "step-by-step argument" (which was turned into one of the "recursiveness conditions" Hilbert and Bernays used in their 1939 characterization of functions that can be evaluated according to rules) was bypassed by Turing. Analyzing human mechanical computations, Turing was led to finiteness conditions that are motivated by the human computer's sensory limitations, but are ultimately based on memory limitations. Then he showed that any function calculable by a human computer satisfying these conditions is also computable by one of his machines. Both Church and Gödel found Turing's analysis convincing; indeed, Church wrote in a 1937 review of Turing's paper that Turing's notion makes "the identification with effectiveness in the ordinary (not explicitly defined) sense evident immediately."

This reflective work of partly philosophical and partly mathematical character provides one of the fundamental notions in mathematical logic. Indeed, its proper understanding is crucial for (judging) the philosophical significance of central metamathematical results – like Gödel's incompleteness theorems or Church's theorem. The work is also crucial for computer science, artificial intelligence, and cognitive psychology, providing in these fields a basic theoretical notion. For example, Church's thesis is *the* cornerstone for Newell and Simon's delimitation of the class of physical symbol systems, i.e. universal machines with a particular architecture; see Newell's *Physical Symbol Systems* (1980). Newell views the delimitation "as the most fundamental contribution of artificial intelligence and computer science to the joint enterprise of cognitive science." In a turn that had been taken by Turing in "Intelligent Machinery" (1948) and "Computing Machinery and Intelligence" (1950), Newell points out the basic role physical symbol systems take on in the study of the human mind: "the hypothesis is that humans are instances of physical symbol systems, and, by virtue of this, mind enters into the physical universe. . . . this hypothesis sets the terms on which we search for a scientific theory of mind."

Church-Turing thesis. See PHILOSOPHY OF MIND.

Cicero, Marcus Tullius (106–43 B.C.), Roman statesman, orator, essayist, and letter writer. He was important not so much for formulating individual philosophical arguments as for expositions of the doctrines of the major schools of Hellenistic philosophy and for, as he put it, "teaching philosophy to speak Latin." The significance of the latter can hardly be overestimated. Cicero's coinages helped shape the philosophical vocabulary of the Latin-speaking West well into the early modern period. The most characteristic feature of Cicero's thought is his attempt to unify philosophy and rhetoric. His first major trilogy, *On the Orator, On the Republic*, and *On the Laws*, presents a vision of wise statesmen-philosophers whose greatest achievement is guiding political affairs through rhetorical persuasion rather than violence. Philosophy, Cicero argues, needs rhetoric to effect its most important practical goals, while rhetoric is useless without the psychological, moral, and logical justification provided by philosophy. This combination of eloquence and philosophy constitutes what he calls *humanitas* – a coinage whose enduring influence is attested in later revivals of humanism – and it alone provides the foundation for constitutional governments; it is acquired, moreover, only through broad training in those subjects worthy of free citizens (*artes liberales*). In philosophy of education, this Ciceronian conception of a humane education encompassing poetry, rhetoric, history, morals, and politics endured as an ideal, especially for those convinced that instruction in the liberal disciplines is essential for citizens if their rational autonomy is to be expressed in ways that are culturally and politically beneficial.

A major aim of Cicero's earlier works is to appropriate for Roman high culture one of Greece's most distinctive products, philosophical theory, and to demonstrate Roman superiority. He thus insists that Rome's laws and political institutions successfully embody the best in Greek political theory, whereas the Greeks themselves were inadequate to the crucial task of putting their theories into practice. Taking over the Stoic conception of the universe as a rational whole, governed by divine reason, he argues that human societies must be grounded in natural law. For Cicero, nature's law possesses the characteristics of a legal code; in particular, it is formulable in a comparatively extended set of rules against which existing societal institutions can be measured. Indeed, since they so closely mirror the requirements of nature, Roman laws and institutions furnish a nearly perfect paradigm for human societies. Cicero's overall theory, if not its particular details, established a lasting framework for anti-positivist theories of law and morality, including those of Aquinas, Grotius, Suárez, and Locke.

The final two years of his life saw the creation of a series of dialogue-treatises that provide an encyclopedic survey of Hellenistic philosophy. Cicero himself follows the moderate fallibilism of Philo of Larissa and the New Academy. Holding that philosophy is a method and not a set of dogmas, he endorses an attitude of systematic doubt. However, unlike Cartesian doubt, Cicero's does not extend to the real world behind phenomena, since he does not envision the possibility of strict phenomenalism. Nor does he take systematic doubt to lead to radical skepticism about knowledge. Although no infallible criterion for distinguishing true from false impressions is available, some impressions are more "persuasive" (*probabile*) and can be relied on to guide action.

His *Academics* offers detailed accounts of Hellenistic epistemological debates, steering a middle course between dogmatism and radical skepticism. A similar strategy governs the rest of his later writings. Cicero presents the views of the major schools, submits them to criticism, and tentatively supports any positions he finds "persuasive." Three connected works, *On Divination, On Fate*, and *On the Nature of the Gods*, survey Epicurean, Stoic, and Academic arguments about theology and natural philosophy. Much of the treatment of religious thought and practice is cool, witty, and skeptically detached – much in the manner of eighteenth-century *philosophes* who, along with Hume, found much in Cicero to emulate. However, he concedes that Stoic arguments for providence are "persuasive." So too in ethics, he criticizes Epicurean, Stoic, and Peripatetic doctrines in *On Ends* (45) and their views on death, pain, irrational emotions, and happiness in *Tusculan Disputations* (45). Yet a final work, *On Duties*, offers a practical ethical system based on Stoic principles. Although sometimes dismissed as the eclecticism of an amateur, Cicero's method of selectively choosing from what had become authoritative professional systems often displays considerable reflectiveness and originality.

circularity. See CIRCULAR REASONING, DEFINITION, DIALLELON.

circular reasoning, reasoning that, when traced backward from its conclusion, returns to that starting point, as one returns to a starting point when tracing a circle. The discussion of this topic by Richard Whatley (1787–1863) in his *Logic* (1826) sets a high standard of clarity and penetration. Logic textbooks often quote the following example from Whatley:

> To allow every man an unbounded freedom of speech must always be, on the whole, advantageous to the State; for it is highly conducive to the interests of the Community, that each individual should enjoy a liberty perfectly unlimited, of expressing his sentiments.

This passage illustrates how circular reasoning is less obvious in a language, such as English, that, in Whatley's words, is "abounding in synonymous expressions, which have no resemblance in sound, and no connection in etymology." The premise and conclusion do not consist of just the same words in the same order, nor can logical or grammatical principles transform one into the other. Rather, they have the same propositional content: they say the same thing in different words. That is why appealing to one of them to provide reason for believing the other amounts to giving something as a reason for itself.

Circular reasoning is often said to *beg the question*. 'Begging the question' and *petitio principii* are translations of a phrase in Aristotle connected with a game of formal disputation played in antiquity but not in recent times. The meanings of 'question' and 'begging' do not in any clear way determine the meaning of 'question begging'.

There is no simple argument form that all and only circular arguments have. It is not logic, in Whatley's example above, that determines the identity of content between the premise and the conclusion. Some theorists propose rather more complicated formal or syntactic accounts of circularity. Others believe that any account of circular reasoning must refer to the beliefs of those who reason. Whether or not the following argument about articles in this dictionary is circular depends on why the first premise should be accepted:

(1) The article on inference contains no split infinitives.
(2) The other articles contain no split infinitives.
Therefore,
(3) No article contains split infinitives.

Consider two cases. Case I: Although (2) supports (1) inductively, both (1) and (2) have solid outside support independent of any prior acceptance of (3). This reasoning is not circular. Case II: Someone who advances the argument accepts (1) or (2) or both, only because he believes (3). Such reasoning is circular, even though neither premise expresses just the same proposition as the conclusion. The question remains controversial whether, in explaining circularity, we should refer to the beliefs of individual reasoners or only to the surrounding circumstances.

One purpose of reasoning is to increase the degree of reasonable confidence that one has in the truth of a conclusion. Presuming the truth of a conclusion in support of a premise thwarts this purpose, because the initial degree of reasonable confidence in the premise cannot then exceed the initial degree of reasonable confidence in the conclusion.

Clarke, Samuel (1675–1729), English philosopher, preacher, and theologian born in Norwich and educated at Cambridge, where he came under the influence of Newton. Upon graduation Clarke entered the established church, serving for a time as chaplain to Queen Anne. He spent the last twenty years of his life as rector of St. James, Westminster. He wrote extensively on controversial theological and philosophical issues – the nature of space and time, proofs of the existence of God, the doctrine of the Trinity, the incorporeality and natural immortality of the soul, freedom of the will, the nature of morality, etc. His most philosophical works are his Boyle lectures of 1704 and 1705, in which he developed a forceful version of the cosmological argument for the existence and nature of God and attacked the views of Hobbes, Spinoza, and some proponents of deism; his correspondence with Leibniz (1715–16), in which he defended Newton's views of space and time and charged Leibniz with holding views inconsistent with free will; and his writings against Anthony Collins, in which he defended a libertarian view of the agent as the undetermined cause of free actions and attacked Collins's arguments for a materialistic view of the mind. In these works Clarke maintains a position of extreme rationalism, contending that the existence and nature of God can be conclusively demonstrated, that the basic principles of morality are necessarily true and immediately knowable, and that the existence of a future state of rewards and punishments is assured by our knowledge that God will reward the morally just and punish the morally wicked. **See also** **HOBBES, LEIBNIZ, PHILOSOPHY OF RELIGION, SPINOZA.** W.L.R.

class, term sometimes used as a synonym for 'set'; when the two are distinguished, a class is understood as a collection in the logical sense, i.e. as the extension of a concept (e.g., the class of red objects), whereas sets, i.e. collections in the mathematical sense, are understood as occurring in stages, where each stage consists of the sets that can be formed from the non-sets and the sets already formed at previous stages. When a set is formed at a given stage, only the non-sets and the previously formed sets are even candidates for membership, but absolutely anything can gain membership in a class simply by falling under the appropriate concept. Thus, it is classes, not sets, that figure in the inconsistent principle of unlimited comprehension. In set theory, *proper classes* are collections of sets that are never formed at any stage, e.g. the class of all sets (since new sets are formed at each stage, there is no stage at which all sets are available to be collected into a set). **See also** **SET THEORY.** P.Mad.

classical republicanism, also known as civic humanism, a political outlook developed by Machiavelli in Renaissance Italy and by James Harrington (1611–77) in seventeenth-century England, modified by eighteenth-century British and Continental writers and important for the thought of the American founding fathers. Drawing on Roman historians, Machiavelli argued that a state could hope for security from the blows of fortune only if its (male) citizens were devoted to its well-being. They should take turns ruling and being ruled, be always prepared to fight for the republic, and limit their private possessions. Such men would possess a wholly secular *virtù* appropriate to political beings. Corruption, in the form of excessive attachment to private interest, would then be the most serious threat to the republic. Harrington's utopian *Oceana* (1656) portrayed England governed under such a system. Opposing the authoritarian views of Hobbes, it described a system in which the well-to-do male citizens would elect some of their number to govern for limited terms. Those governing would propose state policies; the others would vote on the acceptability of the proposals. Agriculture was the basis of economics, but the size of estates was to be strictly controlled. Harringtonianism helped form the views of the political party opposing the dominance of the king and court. Montesquieu in France drew on classical sources in discussing the importance of civic virtue and devotion to the republic.

All these views were well known to Jefferson, Adams, and other American colonial and revolutionary thinkers; and some contemporary communitarian critics of American culture return to classical republican ideas.

Clement of Alexandria (A.D. c.150–c.215), formative teacher in the early Christian church who, as a "Christian gnostic," combined enthusiasm for Greek philosophy with a defense of the church's faith. He espoused spiritual and intellectual ascent toward that complete but hidden knowledge, or *gnosis*, reserved for the truly enlightened. Clement's school did not practice strict fidelity to the authorities, and possibly the teachings, of the institutional church, drawing upon the Hellenistic traditions of Alexandria, including Philo and Middle Platonism. As with the law among the Jews, so, for Clement, philosophy among the pagans was a pedagogical preparation for Christ, in whom *logos*, reason, had become enfleshed. Philosophers now should rise above their inferior understanding to the perfect knowledge revealed in Christ. Though hostile to gnosticism and its speculations, Clement was thoroughly Hellenized in outlook and sometimes guilty of Docetism (the view that Jesus only appeared to have a human body), not least in his reluctance to concede the utter humanness of Jesus. **See also** **GNOSTICISM.** A.E.L.

Clifford, W(illiam) K(ingdon) (1845–79), British mathematician and philosopher. Educated at King's College, London, and Trinity College, Cambridge, he began giving public lectures in 1868, when he was appointed a fellow of Trinity, and in 1870 became professor of applied mathematics at University College, London. His academic career ended prematurely when he died of tuberculosis. Clifford is best known for his rigorous view on the relation between belief and evidence, which, in "The Ethics of Belief," he summarized thus: "It is wrong always, everywhere, and for anyone, to believe anything on insufficient evidence." He gives this example. Imagine a shipowner who sends to sea an emigrant ship, although the evidence raises strong suspicions as to the vessel's seaworthiness. Ignoring this evidence, he convinces himself that the ship's condition is good enough and, after it sinks and all the passengers die, collects his insurance money without a trace of guilt. Clifford maintains that the owner had no *right* to believe in the soundness of the ship. "He had acquired his belief not by honestly earning it in patient investigation, but by stifling his doubts." The right Clifford is alluding to is *moral*, for what one believes is not a private but a public affair and may have grave consequences for others. He regards us as morally obliged to investigate the evidence thoroughly on any occasion, and to withhold belief if evidential support is lacking. This obligation must be fulfilled, however trivial and insignificant a belief may seem, for a violation of it may "leave its stamp upon our character forever." Clifford thus rejected Catholicism, to which he had subscribed originally, and became an agnostic. James's famous essay "The Will to Believe" criticizes Clifford's view. According to James, insufficient evidence need not stand in the way of religious belief, for we have a right to hold beliefs that go beyond the evidence, provided they serve the pursuit of a legitimate goal. **See also** **EPISTEMOLOGY, EVIDENTIALISM.** M.St.

closed formula. See WELL-FORMED FORMULA.

closed loop. See CYBERNETICS.

closed sentence. See OPEN FORMULA.

closure. A set of objects, O, is said to exhibit *closure* or to be *closed* under a given operation, R, provided that for every object, x, if x is a member of O and x is R-related to any object, y, then y is a member of O. For example, the set of propositions is *closed under deduction*, for if p is a proposition and p entails q, i.e. q is deducible from p, then q is a proposition (simply because only propositions can be entailed by propositions). In addition, many subsets of the set of propositions are also closed under deduction. For example, the set of true propositions is closed under deduction or entailment. Others are not. Under most accounts of belief, we may fail to believe what is entailed by what we do, in fact, believe. Thus, if knowledge is some form of true, justified belief, knowledge is not closed under deduction, for we may fail to believe a proposition entailed by a known proposition. Nevertheless, there is a related issue that has been the subject of much debate, namely: is the set of justified propositions closed under deduction? Aside from the obvious importance of the answer to that question in developing an account of justification, there are two important issues in epistemology that also depend on the answer.

Subtleties aside, the so-called Gettier problem depends in large part upon an affirmative answer to that question. For, assuming that a proposition can be justified and false, it is possible to construct cases in which a proposition, say p, is justified, false, but believed. Now, consider a true proposition, q, which is believed and entailed by p.

If justification is closed under deduction, then q is justified, true, and believed. But if the *only* basis for believing q is p, it is clear that q is not known. Thus, true, justified belief is not sufficient for knowledge. What response is appropriate to this problem has been a central issue in epistemology since E. Gettier's publication of "Is Justified True Belief Knowledge?" (*Analysis*, 1963).

Whether justification is closed under deduction is also crucial when evaluating a common, traditional argument for skepticism. Consider any person, S, and let p be any proposition ordinarily thought to be knowable, e.g. that there is a table before S. The argument for skepticism is this:

(1) If p is justified for S, then, since p entails q, where q is 'There is no evil genius making S falsely believe that p', q is justified for S.
(2) S is not justified in believing q.

Therefore, S is not justified in believing p.

The first premise depends upon justification being closed under deduction.

closure, causal. See DAVIDSON.

Coase theorem, a non-formal insight by Ronald Coase (Nobel Prize in Economics, 1991): assuming that there are no (transaction) costs involved in exchanging rights for money, then no matter how rights are initially distributed, rational agents will buy and sell them so as to maximize individual returns. In jurisprudence this proposition has been the basis for a claim about how rights should be distributed even when (as is usual) transaction costs are high: the law should confer rights on those who would purchase them were they for sale on markets without transaction costs; e.g., the right to an indivisible, unsharable resource should be conferred on the agent willing to pay the highest price for it. **See also** PHILOSOPHY OF ECONOMICS. A.R.

Cockburn, Catherine (Trotter) (1679–1749), English philosopher and playwright who made a significant contribution to the debates on ethical rationalism sparked by Clarke's Boyle Lectures (1704–1705). The major theme of her writings is the nature of moral obligation. Cockburn displays a consistent, non-doctrinaire philosophical position, arguing that moral duty is to be rationally deduced from the "nature and fitness of things" (*Remarks*, 1747) and is not founded primarily in externally imposed sanctions. Her writings, published anonymously, take the form of philosophical debates with others, including Samuel Rutherforth, William Warburton, Isaac Watts, Francis Hutcheson, and Lord Shaftesbury. Her best-known intervention in contemporary philosophical debate was her able defense of Locke's *Essay* in 1702. S.H.

coercion. See FREE WILL PROBLEM.

***cogito* argument.** See DESCARTES.

Cogito ergo sum (Latin, 'I think, therefore I am'), the starting point of Descartes's system of knowledge. In his *Discourse on the Method* (1637), he observes that the proposition 'I am thinking, therefore I exist' (*Je pense, donc je suis*) is "so firm and sure that the most extravagant suppositions of the skeptics were incapable of shaking it." The celebrated phrase, in its better-known Latin version, also occurs in the *Principles of Philosophy* (1644), but is not to be found in the *Meditations* (1641), though the latter contains the fullest statement of the reasoning behind Descartes's certainty of his own existence. **See also** DESCARTES. J.Cot.

cognitive architecture. See COGNITIVE SCIENCE.

cognitive dissonance, mental discomfort arising from conflicting beliefs or attitudes held simultaneously. Leon Festinger, who originated the theory of cognitive dissonance in a book of that title (1957), suggested that cognitive dissonance has motivational characteristics. Suppose a person is contemplating moving to a new city. She is considering both Birmingham and Boston. She cannot move to both, so she must choose. Dissonance is experienced by the person if in choosing, say, Birmingham, she acquires knowledge of bad or unwelcome features of Birmingham and of good or welcome aspects of Boston. The amount of dissonance depends on the relative intensities of dissonant elements. Hence, if the only dissonant factor is her learning that Boston is cooler than Birmingham, and she does not regard climate as important, she will experience little dissonance. Dissonance may occur in several sorts of psychological states or processes, although the bulk of research in cognitive dissonance theory has been on dissonance in choice and on the justification and psychological aftereffects of choice. Cognitive dissonance may be involved in two phenomena of interest to philosophers, namely self-deception and weakness of will. Why do self-deceivers try to get themselves to believe something that, in some sense, they know to be false? One may resort to self-deception when knowledge causes dissonance. Why do the weak-willed perform actions they know to be wrong? One may become weak-willed when dissonance arises from the expected consequences of doing the right thing. G.A.G.

cognitive meaning. See MEANING.

cognitive psychology. See COGNITIVE SCIENCE.

cognitive psychotherapy, an expression introduced by Brandt in *A Theory of the Good and the Right* (1979) to refer to a process of assessing and adjusting one's desires, aversions, or pleasures (henceforth, 'attitudes'). This process is central to Brandt's analysis of rationality and, ultimately, to his view on the justification of morality. Cognitive psychotherapy consists in the agent's criticizing his attitudes by repeatedly representing to himself, in an ideally vivid way and at appropriate times, all relevant available information. Brandt characterizes the key definiens as follows: (1) *available information* is "propositions accepted by the science of the agent's day, plus factual propositions justified by publicly accessible evidence (including testimony of others about themselves) and the principles of logic"; (2) information is *relevant*, provided, if the agent were to reflect repeatedly on it, "it would make a difference" – i.e., would affect the attitude in question, and the effect would be a function of its content, not an accidental by-product; (3) relevant information is represented in an *ideally vivid* way when the agent focuses on it with maximal clarity and detail and with no hesitation or doubt about its truth; and (4) *repeatedly* and *at appropriate times* refer, respectively, to the frequency and occasions that would result in the information's having the maximal attitudinal impact. Suppose Mary's desire to smoke were extinguished by her bringing to the focus of her attention, whenever she was about to inhale smoke, some justified beliefs, say that smoking is hazardous to one's health and may cause lung cancer; Mary's desire would have been removed by cognitive psychotherapy.

For Brandt, an attitude is rational for a person provided it is one that would survive, or be produced by, cognitive psychotherapy; otherwise it is irrational. Rational attitudes, in this sense, provide a basis for moral norms. Roughly, the correct moral norms are those of a moral code that persons would opt for if (i) they were motivated by attitudes that survive the process of cognitive psychotherapy; and (ii) at the time of opting for a moral code, they were fully aware of, and vividly attentive to, all available information relevant to choosing a moral code (for a society in which they are to live for the rest of their lives). In this way, Brandt seeks a value-free justification for moral norms – one that avoids the problems of other theories such as those that make an appeal to intuitions.

cognitive science, an interdisciplinary research cluster that seeks to account for intelligent activity, whether exhibited by living organisms (especially adult humans) or machines. Hence, cognitive psychology and artificial intelligence constitute its core. A number of other disciplines, including neuroscience, linguistics, anthropology, and philosophy, as well as other fields of psychology (e.g., developmental psychology), are more peripheral contributors. The quintessential cognitive scientist is someone who employs computer modeling techniques (developing computer programs for the purpose of simulating particular human cognitive activities), but the broad range of disciplines that are at least peripherally constitutive of cognitive science have lent a variety of research strategies to the enterprise. While there are a few common institutions that seek to unify cognitive science (e.g., departments, journals, and societies), the problems investigated and the methods of investigation often are limited to a single contributing discipline. Thus, it is more appropriate to view cognitive science as a cross-disciplinary enterprise than as itself a new discipline.

While interest in cognitive phenomena has historically played a central role in the various disciplines contributing to cognitive science, the term properly applies to cross-disciplinary activities that emerged in the 1970s. During the preceding two decades each of the disciplines that became part of cognitive science gradually broke free of positivistic and behavioristic proscriptions that barred systematic inquiry into the operation of the mind. One of the primary factors that catalyzed new investigations of cognitive activities was Chomsky's generative grammar, which he advanced not only as an abstract theory of the structure of language, but also as an account of language users' mental knowledge of language (their linguistic *competence*). A more fundamental factor was the development of approaches for theorizing about information in an abstract manner, and the introduction of machines (computers) that could manipulate information. This gave rise to the idea that one might program a computer to process information so as to exhibit behavior that would, if performed by a human, require intelligence.

If one tried to formulate a unifying question guiding cognitive science research, it would probably be: how does the cognitive system work? But even this common question is interpreted quite differently in different disciplines. We can appreciate these differences by looking just at language. While psycholinguists (generally psychologists) seek to identify the processing activities in the mind that underlie language use, most linguists focus on the *products* of this internal processing, seeking to articulate the abstract structure of language. A frequent goal of computer scientists, in contrast, has been to develop computer programs to parse natural language input and produce appropriate syntactic and semantic representations.

These differences in objectives among the cognitive science disciplines correlate with different methodologies. The following represent some of the major methodological approaches of the contributing disciplines and some of the problems each encounters.

Artificial intelligence. If the human cognition system is viewed as computational, a natural goal is to simulate its performance. This typically requires formats for representing information as well as procedures for searching and manipulating it. Some of the earliest AI programs drew heavily on the resources of first-order predicate calculus, representing information in propositional formats and manipulating it according to logical principles. For many modeling endeavors, however, it proved important to represent information in larger-scale structures, such as frames (Marvin Minsky), schemata (David Rumelhart), or scripts (Roger Schank), in which different pieces of information associated with an object or activity would be stored together. Such structures generally employed default values for specific slots (specifying, e.g., that deer live in forests) that would be part of the representation unless overridden by new information (e.g., that a particular deer lives in the San Diego Zoo). A very influential alternative approach, developed by Allen Newell, replaces declarative representations of information with procedural representations, known as *productions*. These productions take the form of conditionals that specify actions to be performed (e.g., copying an expression into working memory) if certain conditions are satisfied (e.g., the expression matches another expression).

Psychology. While some psychologists develop computer simulations, a more characteristic activity is to acquire detailed data from human subjects that can reveal the cognitive system's actual operation. This is a challenging endeavor. While cognitive activities transpire within us, they frequently do so in such a smooth and rapid fashion that we are unaware of them. For example, we have little awareness of what occurs when we recognize an object as a chair or remember the name of a client. Some cognitive functions, though, seem to be transparent to consciousness. For example, we might approach a logic problem systematically, enumerating possible solutions and evaluating them serially. Allen Newell and Herbert Simon have refined methods for exploiting verbal protocols obtained from subjects as they solve such problems. These methods have been quite fruitful, but their limitations must be respected. In many cases in which we think we know how we performed a cognitive task, Richard Nisbett and Timothy Wilson have argued that we are misled, relying on folk theories to describe how our minds work rather than reporting directly on their operation. In most cases cognitive psychologists cannot rely on conscious awareness of cognitive processes, but must proceed as do physiologists trying to understand metabolism: they must devise experiments that reveal the underlying processes operative in cognition. One approach is to seek clues in the errors to which the cognitive system is prone. Such errors might be more easily accounted for by one kind of underlying process than by another. Speech errors, such as substituting 'bat cad' for 'bad cat', may be diagnostic of the mechanisms used to construct speech. This approach is often combined with strategies that seek to overload or disrupt the system's normal operation. A common technique is to have a subject perform two tasks at once – e.g., read a passage while watching for a colored spot. Cognitive psychologists may also rely on the ability to dissociate two phenomena (e.g., obliterate one while maintaining the other) to establish their independence. Other types of data widely used to make inferences about the cognitive system include patterns of reaction times, error rates, and priming effects (in which activation of one item facilitates access to related items). Finally, developmental psychologists have brought a variety of data to bear on cognitive science issues. For example, patterns of acquisition times have been used in a manner similar to reaction time patterns, and accounts of the origin and development of systems constrain and elucidate mature systems.

Linguistics. Since linguists focus on a product of cognition rather than the processes that produce the product, they tend to test their analyses directly against our shared knowledge of that product. Generative linguists in the tradition of Chomsky, for instance, develop grammars that they test by probing whether they generate the sentences of the language and no others. While grammars are certainly germane to developing processing models, they do not directly determine the structure of processing models. Hence, the central task of linguistics is not central to cognitive science. However, Chomsky has augmented his work on grammatical description with a number of controversial claims that are psycholinguistic in nature (e.g., his nativism and his notion of linguistic competence). Further, an alternative approach to incorporating psycholinguistic concerns, the *cognitive linguistics* of Lakoff and Langacker, has achieved prominence as a contributor to cognitive science.

Neuroscience. Cognitive scientists have generally assumed that the processes they study are carried out, in humans, by the brain. Until recently, however, neuroscience has been relatively peripheral to cognitive science. In part this is because neuroscientists have been chiefly concerned with the *implementation* of processes, rather than the processes themselves, and in part because the techniques available to neuroscientists (such as single-cell recording) have been most suitable for studying the neural implementation of lower-order processes such as sensation. A prominent exception was the classical studies of brain lesions initiated by Broca and Wernicke, which seemed to show that the location of lesions correlated with deficits in production versus comprehension of speech. (More recent data suggest that lesions in Broca's area impair certain kinds of syntactic processing.) However, other developments in neuroscience promise to make its data more relevant to cognitive modeling in the future. These include studies of simple nervous systems, such as that of *Aplysia* (a genus of marine mollusk) by Eric Kandel, and the development of a variety of techniques for determining the brain activities involved in the performance of cognitive tasks (e.g., recording of evoked response potentials over larger brain structures, and imaging techniques such as positron emission tomography). While in the future neuroscience is likely to offer much richer information that will guide the development and constrain the character of cognitive models, neuroscience will probably not become central to cognitive science. It is itself a rich, multidisciplinary research cluster whose contributing disciplines employ a host of complicated research tools. Moreover, the focus of cognitive science can be expected to remain on cognition, not on its implementation.

So far cognitive science has been characterized in terms of its modes of inquiry. One can also focus on the domains of cognitive phenomena that have been explored. Language represents one such domain. Syntax was one of the first domains to attract wide attention in cognitive science. For example, shortly after Chomsky introduced his transformational grammar, psychologists such as George Miller sought evidence that transformations figured directly in human language processing. From this beginning, a more complex but enduring relationship among linguists, psychologists, and computer scientists has formed a leading edge for much cognitive science research. Psycholinguistics has matured; sophisticated computer models of natural language processing have been developed; and cognitive linguists have offered a particular synthesis that emphasizes semantics, pragmatics, and cognitive foundations of language.

Thinking and reasoning. These constitute an important domain of cognitive science that is closely linked to philosophical interests. Problem solving, such as that which figures in solving puzzles, playing games, or serving as an expert in a domain, has provided a prototype for thinking. Newell and Simon's influential work construed problem solving as a search through a problem space and introduced the idea of *heuristics* – generally reliable but fallible simplifying devices to facilitate the search. One arena for problem solving, scientific reasoning and discovery, has particularly interested philosophers. Artificial intelligence researchers such as Simon and Patrick Langley, as well as philosophers such as Paul Thagard and Lindley Darden, have developed computer programs that can utilize the same data as that available to historical scientists to develop and evaluate theories and plan future experiments. Cognitive scientists have also sought to study the cognitive processes underlying the sorts of logical reasoning (both deductive and inductive) whose normative dimensions have been a concern of philosophers. Philip Johnson-Laird, e.g., has sought to account for human performance in dealing with syllogistic reasoning by describing a processing of constructing and manipulating *mental models*. Finally, the process of constructing and using analogies is another aspect of reasoning that has been extensively studied by traditional philosophers as well as cognitive scientists.

Memory, attention, and learning. Cognitive scientists have differentiated a variety of memory types. The distinction between long- and short-term memory was very influential in the information-processing models of the 1970s. Short-term memory was characterized by limited capacity, such as that exhibited by the ability to retain a seven-digit telephone number for a short period. In much cognitive science work, the notion of *working memory* has superseded *short-term memory*, but many theorists are reluctant to construe this as a separate memory system (as opposed to a part of long-term memory that is activated at a given time). Endel Tulving introduced a distinction between semantic memory (general knowledge that is not specific to a time or place) and episodic memory (memory for particular episodes or occurrences). More recently, Daniel Schacter proposed a related distinction that emphasizes consciousness: implicit memory (access without awareness) versus explicit memory (which does involve awareness and is similar to episodic memory). One of the interesting results of cognitive research is the dissociation between different kinds of memory: a person might have severely impaired memory of recent events while having largely unimpaired implicit memory. More generally, memory research has shown that human memory does not simply store away information as in a file cabinet. Rather, information is organized according to preexisting structures such as scripts, and can be influenced by events subsequent to the initial storage. Exactly what gets stored and retrieved is partly determined by *attention*, and psychologists in the information-processing tradition have sought to construct general cognitive models that emphasize memory and attention. Finally, the topic of learning has once again become prominent. Extensively studied by the behaviorists of the precognitive era, learning was superseded by memory and attention as a research focus in the 1970s. In the 1980s, artificial intelligence researchers developed a growing interest in designing systems that can learn; machine learning is now a major problem area in AI. During the same period, connectionism arose to offer an alternative kind of learning model.

Perception and motor control. Perceptual and motor systems provide the inputs and outputs to cognitive systems. An important aspect of perception is the recognition of something as a particular *kind* of object or event; this requires accessing knowledge of objects and events. One of the central issues concerning perception questions the extent to which perceptual processes are influenced by higher-level cognitive information (top-down processing) versus how much they are driven purely by incoming sensory information (bottom-up processing). A related issue concerns the claim that visual imagery is a distinct cognitive process and is closely related to visual perception, perhaps relying on the same brain processes. A number of cognitive science inquiries (e.g., by Roger Shepard and Stephen Kosslyn) have focused on how people use images in problem solving and have sought evidence that people solve problems by rotating images or scanning them. This research has been extremely controversial, as other investigators have argued against the use of images and have tried to account for the performance data that have been generated in terms of the use of propositionally represented information. Finally, a distinction recently has been proposed between the *What* and *Where* systems. All of the foregoing issues concern the *What* system (which recognizes and represents objects as exemplars of categories). The *Where* system, in contrast, concerns objects in their environment, and is particularly adapted to the dynamics of movement. Gibson's ecological psychology is a long-standing inquiry into this aspect of perception, and work on the neural substrates is now attracting the interest of cognitive scientists as well.

Recent developments. The breadth of cognitive science has been expanding in recent years. In the 1970s, cognitive science inquiries tended to focus on processing activities of adult humans or on computer models of intelligent performance; the best work often combined these approaches. Subsequently, investigators examined in much greater detail how cognitive systems develop, and developmental psychologists have increasingly contributed to cognitive science. One of the surprising findings has been that, contrary to the claims of William James, infants do not seem to confront the world as a "blooming, buzzing confusion," but rather recognize objects and events quite early in life. Cognitive science has also expanded along a different dimension. Until recently many cognitive studies focused on what humans could accomplish in laboratory settings in which they performed tasks isolated from real-life contexts. The motivation for this was the assumption that cognitive processes were generic and not limited to specific contexts. However, a variety of influences, including Gibsonian ecological psychology (especially as interpreted and developed by Ulric Neisser) and Soviet activity theory, have advanced the view that cognition is much more dynamic and situated in real-world tasks and environmental contexts; hence, it is necessary to study cognitive activities in an ecologically valid manner.

Another form of expansion has resulted from a challenge to what has been the dominant architecture for modeling cognition. An *architecture* defines the basic processing capacities of the cognitive system. The dominant cognitive architecture has assumed that the mind possesses a capacity for storing and manipulating symbols. These symbols can be composed into larger structures according to syntactic rules that can then be operated upon by formal rules that recognize that structure. Jerry Fodor has referred to this view of the cognitive system as the "language of thought hypothesis" and clearly construes it as a modern heir of rationalism. One of the basic arguments for it, due to Fodor and Zenon Pylyshyn, is that thoughts, like language, exhibit productivity (the unlimited capacity to generate new thoughts) and systematicity (exhibited by the inherent relation between thoughts such as 'Joan loves the florist' and 'The florist loves Joan'). They argue that only if the architecture of cognition has language-like compositional structure would productivity and systematicity be generic properties and hence not require special case-by-case accounts. The challenge to this architecture has arisen with the development of an alternative architecture, known as *connectionism, parallel distributed processing*, or *neural network modeling*, which proposes that the cognitive system consists of vast numbers of neuron-like units that excite or inhibit each other. Knowledge is stored in these systems by the adjustment of connection strengths between processing units; consequently, connectionism is a modern descendant of associationism. Connectionist networks provide a natural account of certain cognitive phenomena that have proven challenging for the symbolic architecture, including pattern recognition, reasoning with soft constraints, and learning. Whether they also can account for productivity and systematicity has been the subject of debate.

Philosophical theorizing about the mind has often provided a starting point for the modeling and empirical investigations of modern cognitive science. The ascent of cognitive science has not meant that philosophers have ceased to play a role in examining cognition. Indeed, a number of philosophers have pursued their inquiries as contributors to cognitive science, focusing on such issues as the possible reduction of cognitive theories to those of neuroscience, the status of folk psychology relative to emerging scientific theories of mind, the merits of rationalism versus empiricism, and strategies for accounting for the intentionality of mental states. The interaction between philosophers and other cognitive scientists, however, is bidirectional, and a number of developments in cognitive science promise to challenge or modify traditional philosophical views of cognition. For example, studies by cognitive and social psychologists have challenged the assumption that human thinking tends to accord with the norms of logic and decision theory. On a variety of tasks humans seem to follow procedures (heuristics) that violate normative canons, raising questions about how philosophers should characterize rationality. Another area of empirical study that has challenged philosophical assumptions has been the study of concepts and categorization. Philosophers since Plato have widely assumed that concepts of ordinary language, such as *red*, *bird*, and *justice*, should be definable by necessary and sufficient conditions. But celebrated studies by Eleanor Rosch and her colleagues indicated that many ordinary-language concepts had a *prototype structure* instead. On this view, the categories employed in human thinking are characterized by prototypes (the clearest exemplars) and a metric that grades exemplars according to their degree of typicality. Recent investigations have also pointed to significant instability in conceptual structure and to the role of theoretical beliefs in organizing categories. This alternative conception of concepts has profound implications for philosophical methodologies that portray philosophy's task to be the analysis of concepts.

cognitive science of religion (CSR), the field comprising any of a variety of scientific projects unified by their attempt to describe and explain various religious beliefs, behaviors, and dispositions using the methods and theories of cognitive psychology and evolutionary theory. Like cognitive science itself, research in the area is highly interdisciplinary, with contributions from cognitive scientists, evolutionary theorists, anthropologists, and philosophers.

Although inventing possible explanations of religious beliefs and behavior is an age-old pastime, CSR is unique in (1) its attempt to test possible explanations by experiment and by comparison with anthropological data, and (2) its attempt to ground explanations of religious beliefs, behaviors, and dispositions in the features and capacities of the human mind and the evolutionary pressures that early humans likely faced. CSR traces its origins to work in the 1990s by anthropologist Stewart Guthrie, religion scholar E. Thomas Lawson, and philosopher Robert McCauley, but it grew rapidly in the 2000s in part because of the influence of the work of cognitive anthropologists Pascal Boyer and Scott Atran, and cognitive psychologist Justin Barrett. Although CSR is a recent movement in the study of religion, it is motivated by a very old observation: as Hume stated in his *Natural History of Religion* (1757), "the belief of invisible, intelligent power has been very generally diffused over the human race, in all places and in all ages." Hume's observation puts religious beliefs firmly in the purview of cognitive science and evolutionary psychology, which attempt to explain the existence and features of universal (or naturally developing) features of the human mind.

The basic premise of CSR is that since religious belief and behavior is historically widespread and resistant to eradication – religion does not (typically) fold, but rather mutates under pressure – there must be something about the structure of the human mind and the selective pressures humans faced that disposes humans to form religious beliefs and to engage in religious behavior. Researchers in CSR do not believe they can, nor do they attempt to, provide a complete explanation of the details of any given individual's religious beliefs and behavior. They admit that much of the structure of belief and behavior associated with specific religious traditions will be explained largely by historical factors regarding the environment, people, and societies related to the tradition. Rather, researchers aim to explain *patterns* of belief and behavior, such as that humans tend to believe in invisible agents who care about the behavior of living humans and that through rituals and prayer humans can communicate with and appease such agents.

One of the central disputes among researchers in CSR is whether various central kinds of religious belief and behavior were adaptations, spandrels (or by-products), or "exaptations." An adaptation is a trait that was selected for; a spandrel is a trait that was not selected for, but is associated with other traits that were selected for; an exaptation is a trait that was originally a spandrel, but was later selected for. Several of the most prominent researchers in the field, e.g. Atran, Barrett, and Boyer, advocate a spandrel view. Although their views vary somewhat in details, they all hold that belief in invisible agents (such as gods and ancestor spirits) fits well with various mechanisms of the human mind and that those mechanisms were not selected for their ability to accurately represent and describe invisible agents. They suggest several such mental mechanisms; here we describe just two. First, they all argue that concepts of invisible agents like God are intuitively engaging, and easily passed along and pondered by humans because they are minimally counterintuitive. A minimally counterintuitive concept, e.g. that of a Greek god, violates just enough of our expectations for ontological categories like *person* to stand out as strange, but is not strange enough to preclude reasoning about the entity and how it might behave in our world. They present experimental evidence that people tend to recall instances of minimally counterintuitive concepts (e.g., a rock that hears your thoughts) better than instances of intuitive concepts (e.g., a rock with sharp edges) and instances of strongly counterintuitive concepts (e.g., an invisible teleporting rock that can hear everything that happens around it, but that cannot talk). Second, Barrett argues that human minds possess a hypersensitive agency detection device (HADD). HADD disposes humans to suspect the presence of an agent (i.e., a being with a mind that acts on beliefs and desires) when given even ambiguous evidence of the presence of an agent. For Barrett, HADD is likely an adaptation because agents are particularly dangerous or helpful entities. There is little cost to a false positive, but often great cost to a false negative: not detecting an agent nearby could lead to being killed or to missing a chance to cooperate with a fellow human. One of HADD's side effects is that humans will be disposed to believe in invisible agents such as gods since we often encounter strange events that invisible agents could easily explain. This disposition is reinforced by the minimal counterintuitiveness of "god concepts"; gods grip our attention, and thus make attractive candidates for explaining various strange events that seem to us, via HADD, to be agentially caused.

Exaptationists accept the basic ideas of the spandrel theory, but add that selection acted on the disposition to believe in invisible agents once humans obtained the disposition. In general, they theorize that religion has the ability to enhance cooperation and that, in virtue of this, various kinds of religious belief and activity are adaptive. Jesse Bering and Dominic Johnson's "Supernatural Punishment Theory" states that the threat of supernatural punishment from a god who cares about how humans behave makes them less likely to engage in cheating; that is adaptive because – since they believe that gods would know whether they cheat – it makes them less likely to risk suffering the negative consequences of attempting to cheat (and failing). Joseph Bulbulia suggests, instead, that belief in a god who cares about how humans behave is adaptive when true believers in such a god can reliably find each other and cooperate; this is so because they will benefit greatly from more honest cooperative exchanges. However, to find each other, true believers have to be able to send a "costly, hard-to-fake" signal to identify one another. Bulbulia sees rituals, the possession and communication of theological knowledge, dress codes, food restrictions, and other characteristic religious behaviors as examples of such signals. So in order to get the great benefits of honest cooperative exchanges, such religious behavior evolved alongside a disposition toward believing in gods who care about morality.

Some adaptationists, e.g. Richard Sosis, argue that religious belief and behavior are adaptive because (through costly signaling) they increase cooperation among adherents. Sosis also suggests that the components of a religion can interact to produce emergent properties that render individual adherents adaptive in their socioecological environment. David Sloan Wilson, on the other hand, argues that religious beliefs and behaviors are adaptively advantageous on the group level. That is, groups that engage in religious behaviors and hold religious beliefs are more likely to survive and reproduce, and thus religious behaviors and beliefs are selected for. Religious groups are more likely to survive and reproduce because religious commitments and behaviors make a group more cohesive and more likely to cooperate, and make it more likely that the group will contain individuals that will sacrifice their own interests for the good of the group.

These theories of the origin and persistence of religious beliefs and behaviors raise the philosophical question: if these theories are accurate, would religious beliefs such as belief in God be rational or justified? Of course, none of these theories entail that God does not exist. However, Paul Griffiths, John Wilkins, and others have argued that since the CSR theories show that the belief-forming and -sustaining processes for belief in God do not track the truth – because humans would believe in God (or invisible agents of some kind) whether or not they existed – we should suspend judgment about whether God exists. One reply found in literature responsive to CSR is that if God exists, then CSR processes could be designed to track the truth, so we cannot tell whether the processes track the truth unless we know whether God exists. Another is that there may well be good reason to believe in God if some of the traditional theistic arguments succeed, even if CSR research shows that there is a general human disposition toward belief in invisible agents. Whichever way the arguments lean, the emerging theories of CSR have led to a productive discussion in the epistemology of religion about whether and when naturalistic explanations can debunk or undermine religious belief.

cognitive value. See FREGE.

Cohen, Hermann (1842–1918), German Jewish philosopher who originated and led, with Paul Natorp (1854–1924), the Marburg School of neo-Kantianism. He taught at Marburg from 1876 to 1912. He wrote commentaries on Kant's *Critiques* prior to publishing *System der Philosophie* (1902–12), which consisted of parts on logic, ethics, and aesthetics. He developed a Kantian idealism of the natural sciences, arguing that a transcendental analysis of these sciences shows that "pure thought" (his system of Kantian a priori principles) "constructs" their "reality." He also developed Kant's ethics as a democratic socialist ethics. He ended his career at a rabbinical seminary in Berlin, writing his influential *Religion der Vernunft aus den Quellen des Judentums* ("Religion of Reason out of the Sources of Judaism," 1919), which explicated Judaism on the basis of his own Kantian ethical idealism. Cohen's ethical-political views were adopted by Kurt Eisner (1867–1919), leader of the Munich revolution of 1918, and also had an impact on the revisionism (of orthodox Marxism) of the German Social Democratic Party, while his philosophical writings greatly influenced Cassirer. **See also** CASSIRER, KANT, NEO-KANTIANISM. coherence theory of justification. See COHERENTISM.

coherence theory of knowledge. See COHERENTISM.

coherence theory of truth, the view that either the nature of truth or the sole criterion for determining truth is constituted by a relation of coherence between the belief (or judgment) being assessed and other beliefs (or judgments). As a view of the nature of truth, the coherence theory represents an alternative to the correspondence theory of truth. Whereas the correspondence theory holds that a belief is true provided it corresponds to independent reality, the coherence theory holds that it is true provided it stands in a suitably strong relation of coherence to other beliefs, so that the believer's total system of beliefs forms a highly or perhaps perfectly coherent system. Since, on such a characterization, truth depends entirely on the internal relations within the system of beliefs, such a conception of truth seems to lead at once to idealism as regards the nature of reality, and its main advocates have been proponents of absolute idealism (mainly Bradley, Bosanquet, and Brand Blanshard). A less explicitly metaphysical version of the coherence theory was also held by certain members of the school of logical positivism (mainly Otto Neurath and Carl Hempel).

The nature of the intended relation of coherence, often characterized metaphorically in terms of the beliefs in question fitting together or dovetailing with each other, has been and continues to be a matter of uncertainty and controversy. Despite occasional misconceptions to the contrary, it is clear that coherence is intended to be a substantially more demanding relation than mere consistency, involving such things as inferential and explanatory relations within the system of beliefs. Perfect or ideal coherence is sometimes described as requiring that every belief in the system of beliefs entails all the others (though it must be remembered that those offering such a characterization do not restrict entailments to those that are formal or analytic in character). Since actual human systems of belief seem inevitably to fall short of perfect coherence, however that is understood, their truth is usually held to be only approximate at best, thus leading to the absolute idealist view that truth admits of degrees.

As a view of the criterion of truth, the coherence theory of truth holds that the sole criterion or standard for determining whether a belief is true is its coherence with other beliefs or judgments, with the degree of justification varying with the degree of coherence. Such a view amounts to a coherence theory of epistemic justification. It was held by most of the proponents of the coherence theory of the nature of truth, though usually without distinguishing the two views very clearly.

For philosophers who hold both of these views, the thesis that coherence is the sole criterion of truth is usually logically prior, and the coherence theory of the nature of truth is adopted as a consequence, the clearest argument being that only the view that perfect or ideal coherence is the nature of truth can make sense of the appeal to degrees of coherence as a criterion of truth.

See also COHERENTISM, IDEALISM, TRUTH. L.B.

coherentism, in epistemology, a theory of the structure of knowledge or justified beliefs according to which all beliefs representing knowledge are known or justified in virtue of their relations to other beliefs, specifically, in virtue of belonging to a coherent system of beliefs. Assuming that the orthodox account of knowledge is correct at least in maintaining that justified true belief is necessary for knowledge, we can identify two kinds of coherence theories of knowledge: those that are coherentist merely in virtue of incorporating a coherence theory of justification, and those that are doubly coherentist because they account for both justification and truth in terms of coherence. What follows will focus on coherence theories of justification.

Historically, coherentism is the most significant alternative to foundationalism. The latter holds that some beliefs, basic or foundational beliefs, are justified apart from their relations to other beliefs, while all other beliefs derive their justification from that of foundational beliefs. Foundationalism portrays justification as having a structure like that of a building, with certain beliefs serving as the foundations and all other beliefs supported by them. Coherentism rejects this image and pictures justification as having the structure of a raft. Justified beliefs, like the planks that make up a raft, mutually support one another. This picture of the coherence theory is due to the positivist Otto Neurath. Among the positivists, Hempel shared Neurath's sympathy for coherentism. Other defenders of coherentism from the late nineteenth and early twentieth centuries were idealists, e.g. Bradley, Bosanquet, and Brand Blanshard. (Idealists often held the sort of double coherence theory mentioned above.)

The contrast between foundationalism and coherentism is commonly developed in terms of the regress argument. If we are asked what justifies one of our beliefs, we characteristically answer by citing some other belief that supports it, e.g. logically or probabilistically. If we are asked about this second belief, we are likely to cite a third belief, and so on. There are three shapes such an evidential chain might have: it could go on forever, it could eventually end in some belief, or it could loop back upon itself, i.e. eventually contain again a belief that had occurred "higher up" on the chain. Assuming that infinite chains are not really possible, we are left with a choice between chains that end and circular chains. According to foundationalists, evidential chains must eventually end with a foundational belief that is justified, if the belief at the beginning of the chain is to be justified. Coherentists are then portrayed as holding that circular chains can yield justified beliefs.

This portrayal is, in a way, correct. But it is also misleading since it suggests that the disagreement between coherentism and foundationalism is best understood as concerning only the structure of evidential chains. Talk of evidential chains in which beliefs that are further down on the chain are responsible for beliefs that are higher up naturally suggests the idea that just as real chains transfer forces, evidential chains transfer justification. Foundationalism then sounds like a real possibility. Foundational beliefs already have justification, and evidential chains serve to pass the justification along to other beliefs. But coherentism seems to be a nonstarter, for if no belief in the chain is justified to begin with, there is nothing to pass along. Altering the metaphor, we might say that coherentism seems about as likely to succeed as a bucket brigade that does not end at a well, but simply moves around in a circle.

The coherentist seeks to dispel this appearance by pointing out that the primary function of evidential chains is not to transfer epistemic status, such as justification, from belief to belief. Indeed, beliefs are not the primary locus of justification. Rather, it is whole systems of belief that are justified or not in the primary sense; individual beliefs are justified in virtue of their membership in an appropriately structured system of beliefs. Accordingly, what the coherentist claims is that the appropriate sorts of evidential chains, which will be circular – indeed, will likely contain numerous circles – constitute justified systems of belief. The individual beliefs within such a system are themselves justified in virtue of their place in the entire system and not because this status is passed on to them from beliefs further down some evidential chain in which they figure. One can, therefore, view coherentism with considerable accuracy as a version of foundationalism that holds all beliefs to be foundational. From this perspective, the difference between coherentism and traditional foundationalism has to do with what accounts for the epistemic status of foundational beliefs, with traditional foundationalism holding that such beliefs can be justified in various ways, e.g. by perception or reason, while coherentism insists that the only way such beliefs can be justified is by being a member of an appropriately structured system of beliefs.

One outstanding problem the coherentist faces is to specify exactly what constitutes a coherent system of beliefs. Coherence clearly must involve much more than mere absence of mutually contradictory beliefs. One way in which beliefs can be logically consistent is by concerning completely unrelated matters, but such a consistent system of beliefs would not embody the sort of mutual support that constitutes the core idea of coherentism. Moreover, one might question whether logical consistency is even necessary for coherence, e.g. on the basis of the preface paradox. Similar points can be made regarding efforts to begin an account of coherence with the idea that beliefs and degrees of belief must correspond to the probability calculus. So although it is difficult to avoid thinking that such formal features as logical and probabilistic consistency are significantly involved in coherence, it is not clear exactly how they are involved. An account of coherence can be drawn more directly from the following intuitive idea: a coherent system of belief is one in which each belief is epistemically supported by the others, where various types of epistemic support are recognized, e.g. deductive or inductive arguments, or inferences to the best explanation. There are, however, at least two problems this suggestion does not address. First, since very small sets of beliefs can be mutually supporting, the coherentist needs to say something about the scope a system of beliefs must have to exhibit the sort of coherence required for justification. Second, given the possibility of small sets of mutually supportive beliefs, it is apparently possible to build a system of very broad scope out of such small sets of mutually supportive beliefs by mere conjunction, i.e. without forging any significant support relations among them. Yet, since the interrelatedness of all truths does not seem discoverable by analyzing the concept of justification, the coherentist cannot rule out epistemically isolated subsystems of belief entirely. So the coherentist must say what sorts of isolated subsystems of belief are compatible with coherence.

The difficulties involved in specifying a more precise concept of coherence should not be pressed too vigorously against the coherentist. For one thing, most foundationalists have been forced to grant coherence a significant role within their accounts of justification, so no dialectical advantage can be gained by pressing them. Moreover, only a little reflection is needed to see that nearly all the difficulties involved in specifying coherence are manifestations within a specific context of quite general philosophical problems concerning such matters as induction, explanation, theory choice, the nature of epistemic support, etc. They are, then, problems that are faced by logicians, philosophers of science, and epistemologists quite generally, regardless of whether they are sympathetic to coherentism. Coherentism faces a number of serious objections. Since according to coherentism justification is determined solely by the relations among beliefs, it does not seem to be capable of taking us outside the circle of our beliefs. This fact gives rise to complaints that coherentism cannot allow for any input from external reality, e.g. via perception, and that it can neither guarantee nor even claim that it is likely that coherent systems of belief will make contact with such reality or contain true beliefs. And while it is widely granted that justified false beliefs are possible, it is just as widely accepted that there is an important connection between justification and truth, a connection that rules out accounts according to which justification is not truth-conducive. These abstractly formulated complaints can be made more vivid, in the case of the former, by imagining a person with a coherent system of beliefs that becomes frozen, and fails to change in the face of ongoing sensory experience; and in the case of the latter, by pointing out that, barring an unexpected account of coherence, it seems that a wide variety of coherent systems of belief are possible, systems that are largely disjoint or even incompatible.

collective action, action by several agents who are suitably socially connected, e.g. are acting on the shared goal to go together for lunch. Here the same type of action is cooperatively performed, with each agent knowing that the others are also performing it or a related type of action. The social connectedness of participants in a collective social action can in its most central sense be taken to refer to the social attitude, especially "we-attitude" or "we-state", shared by the participants. The attitude can be a want, goal, intention, belief, wish, hope, feeling, etc. Consider intentions, which are attitudes or mental states that arguably each intentionally performed action requires. Take the following kinds of intention and their contents: (a) my intention to achieve *X* (e.g., that the yard be tidy), (b) our joint intention to achieve *X*. We can call (a) an *I-content* because it refers to a single agent *qua* 'I', while analogously we can call (b) *we-content*. An intention can be had (i) individualistically, namely on the part of the intender, or (ii) collectivistically, on the part of one's group (or altruistically for some other agent, a case here ignored). With collective action, it is "we" who are at stake (case (ii)) and we are "in the same boat." We can call (i) the *I-mode* way of having an intention (or, for that matter, any mental state) and (ii) the *we-mode* way. We then get four kinds of collective action, since both modes can have either individual or collective content.

Collective (or, here equivalently, joint) intentions typically have collective action as their content (and their condition of satisfaction), but sometimes also single individual action can be collectively intended (e.g., we may intend that one of us does *X*). Collective action that is fully intentional must be performed *on* a collective intention and, in general, partly because of a relevant shared reason. In some cases the joint intention or shared goal in question involves strategic interdependence between the agents. A typical example is a *public good* case where the performance of the collective action does not require *all* members of the collective to contribute to the shared goal, though all members can enjoy the good (e.g., public medical services) when achieved.

collective belief, a belief or a view attributed to a group or collection of individuals, e.g. that farmers believe that cows moo with an accent or that the government believes that the economy will expand 4.0 percent next year. Two senses of 'collective belief' should be distinguished. In a summative sense, collective beliefs are those of the group members. In this sense, the first example above could mean that all or most farmers believe that cows moo with an accent. In a non-summative – perhaps *mutuality* – sense, collective beliefs are opinions that the members of the group have collectively adopted as their group's view. Under such an interpretation, the example could mean that, roughly, farmers have agreed that it is their view as a group that cows moo with an accent.

Philosophical interest has focused on non-summative collective beliefs because of their irreducibility to group members' beliefs with the same content. Margaret Gilbert has argued with respect to non-summative beliefs that a group may lack beliefs that its members share, and a group may have beliefs that its members lack. For instance, the members of the government may all believe that today's weather is nice without the government having beliefs about today's weather. In contrast, the government may have a belief that the economy will expand 4.0 percent, although half of the members believe that the economy will expand 3.0 percent and the rest that it will expand 5.0 percent.

Within the literature concerning collective intentionality (which extends to collective desire, collective attitudes, collective judgment, and other propositional attitudes) there have been debates over the role of collective beliefs in social ontology and group agency, over whether non-summative collective beliefs are real beliefs or acceptances, and over whether collective beliefs can constitute collective knowledge.

Collier, Arthur (1680–1732), English philosopher, a Wiltshire parish priest whose *Clavis Universalis* (1713) defends a version of immaterialism closely akin to Berkeley's. Matter, Collier contends, "exists in, or in dependence on mind." He emphatically affirms the existence of bodies and, like Berkeley, defends immaterialism as the only alternative to skepticism. Collier grants that bodies seem to be external, but their "quasi-externeity" is only the effect of God's will. In Part I of the *Clavis* Collier argues (as Berkeley had in his *New Theory of Vision*, 1709) that the visible world is not external. In Part II he argues (as Berkeley had in the *Principles*, 1710, and *Three Dialogues*, 1713) that the external world "is a being utterly impossible." Two of Collier's arguments for the "intrinsic repugnancy" of the external world resemble Kant's first and second antinomies. Collier argues, e.g., that the material world is both finite and infinite; the contradiction can be avoided, he suggests, only by denying its external existence.

Some scholars suspect that Collier deliberately concealed his debt to Berkeley; most accept his report that he arrived at his views ten years before he published them. Collier first refers to Berkeley in letters written in 1714–15. In *A Specimen of True Philosophy* (1730), where he offers an immaterialist interpretation of the opening verse of Genesis, Collier writes that "except a single passage or two" in Berkeley's *Dialogues*, there is no other book "which I ever heard of" on the same subject as the *Clavis*. This is a puzzling remark on several counts, one being that in the Preface to the *Dialogues*, Berkeley describes his earlier books. Collier's biographer reports seeing among his papers (now lost) an outline, dated 1708, on "the question of the visible world being without us or not," but he says no more about it. The biographer concludes that Collier's independence cannot reasonably be doubted; perhaps the outline would, if unearthed, establish this.

Collingwood, R(obin) G(eorge) (1889–1943), English philosopher and historian. His father, W. G. Collingwood, John Ruskin's friend, secretary, and biographer, at first educated him at home in Coniston and later sent him to Rugby School and then Oxford. Immediately upon graduating in 1912, he was elected to a fellowship at Pembroke College; except for service with admiralty intelligence during World War I, he remained at Oxford until 1941, when illness compelled him to retire. Although his *Autobiography* expresses strong disapproval of the lines on which, during his lifetime, philosophy at Oxford developed, he was a university "insider." In 1934 he was elected to the Waynflete Professorship. He was also a leading archaeologist of Roman Britain.

Although as a student Collingwood was deeply influenced by the "realist" teaching of John Cook Wilson, he studied not only the British idealists, but also Hegel and the contemporary Italian post-Hegelians. At twenty-three, he published a translation of Croce's book on Vico's philosophy. *Religion and Philosophy* (1916), the first of his attempts to present orthodox Christianity as philosophically acceptable, has both idealist and Cook Wilsonian elements. Thereafter the Cook Wilsonian element steadily diminished. In *Speculum Mentis* (1924), he investigated the nature and ultimate unity of the four special 'forms of experience' – art, religion, natural science, and history – and their relation to a fifth comprehensive form – philosophy. While all four, he contended, are necessary to a full human life now, each is a form of error that is corrected by its less erroneous successor. Philosophy is error-free but has no content of its own: "The truth is not some perfect system of philosophy: it is simply the way in which all systems, however perfect, collapse into nothingness on the discovery that they are only systems." Some critics dismissed this enterprise as idealist (a description Collingwood accepted when he wrote), but even those who favored it were disturbed by the apparent skepticism of its result. A year later, he amplified his views about art in *Outlines of a Philosophy of Art*.

Since much of what Collingwood went on to write about philosophy has never been published, and some of it has been negligently destroyed, his thought after *Speculum Mentis* is hard to trace. It will not be definitively established until the more than three thousand pages of his surviving unpublished manuscripts (deposited in the Bodleian Library in 1978) have been thoroughly studied. They were not available to the scholars who published studies of his philosophy as a whole up to 1990.

Three trends in how his philosophy developed, however, are discernible. The first is that as he continued to investigate the four special forms of experience, he came to consider each valid in its own right, and not a form of error. As early as 1928, he abandoned the conception of the historical past in *Speculum Mentis* as simply a spectacle, alien to the historian's mind; he now proposed a theory of it as thoughts explaining past actions that, although occurring in the past, can be rethought in the present. Not only can the identical thought "enacted" at a definite time in the past be "reenacted" any number of times after, but it can be known to be so reenacted if physical evidence survives that can be shown to be incompatible with other proposed reenactments. In 1933–34 he wrote a series of lectures (posthumously published as *The Idea of Nature*) in which he renounced his skepticism about whether the quantitative material world can be known, and inquired why the three constructive periods he recognized in European scientific thought, the Greek, the Renaissance, and the modern, could each advance our knowledge of it as they did. Finally, in 1937, returning to the philosophy of art and taking full account of Croce's later work, he showed that imagination expresses emotion and becomes false when it counterfeits emotion that is not felt; thus he transformed his earlier theory of art as purely imaginative. His later theories of art and of history remain alive; and his theory of nature, although corrected by research since his death, was an advance when published.

The second trend was that his conception of philosophy changed as his treatment of the special forms of experience became less skeptical. In his beautifully written *Essay on Philosophical Method* (1933), he argued that philosophy has an object – the *ens realissimum* as the one, the true, and the good – of which the objects of the special forms of experience are appearances; but that implies what he had ceased to believe, that the special forms of experience are forms of error. In his *Principles of Art* (1938) and *New Leviathan* (1942) he denounced the idealist principle of *Speculum Mentis* that to abstract is to falsify. Then, in his *Essay on Metaphysics* (1940), he denied that metaphysics is the science of being *qua* being, and identified it with the investigation of the "absolute presuppositions" of the special forms of experience at definite historical periods.

A third trend, which came to dominate his thought as World War II approached, was to see serious philosophy as practical, and so as having political implications. He had been, like Ruskin, a radical Tory, opposed less to liberal or even some socialist measures than to the bourgeois ethos from which they sprang. Recognizing European fascism as the barbarism it was, and detesting anti-Semitism, he advocated an anti-fascist foreign policy and intervention in the Spanish Civil War in support of the republic. His last major publication, *The New Leviathan*, impressively defends what he called civilization against what he called barbarism; and although it was neglected by political theorists after the war was won, the collapse of Communism and the rise of Islamic states are winning it new readers.

color, as most commonly conceived, a visible property of a surface, such as being red, blue, orange, or black. The philosophical problem of color is to explain the nature of colors, where they are instantiated, and how they fit, or do not fit, into the world described by physics and chemistry.

Color primitivism and *color projectivism* make two claims. First, redness (e.g.) is a qualitative, sensuous, non-relational property of the sort we visually attribute to ripe tomatoes we see in normal lighting conditions. Second, colors are non-physical properties that play no role in physical theory and do not causally interact with physical objects. Primitivism goes on to claim that colors are instantiated in the objects we see as colored, and that we commonly see the colors of objects veridically. Problem: how can light reflected from objects carry information to our eyes about the colors of those objects if colors are not physical properties that interact with light? Projectivism holds that the objects we see only *look* colored: when we see objects as colored, our visual systems misrepresent them. Some projectivists hold that colors are instantiated in the visual system, others that they are uninstantiated properties. Problem: projectivism seems to have the implausible consequence that color experiences contain no information about the world and thus our color experiences are not useful in guiding behavior.

Color realism, probably the most widely held view among contemporary philosophers, holds that redness (e.g.) is identical to a physically constituted property instantiated in red objects, such as the micro-structural properties that determine the way objects reflect light when they look red under normal conditions; and similarly for other colors. What primitivism and projectivism call colors are really sensations of color. Since many different objects that appear to be the same shade of red have different micro-structures, the realist holds that redness is a set of physical properties. Problem: it is not clear that the redness, as a set, enters into causal interactions. If the redness set does not enter into causal interactions, how does light carry to our eyes the information that red objects are red?

On *color relationalism*, colors are triadic relations between perceivers, objects, and lighting conditions. For example, on one form of relationalism – *dispositionalism* – an object is red if and only if it looks, or would look, red to normal perceivers under normal conditions. Problem: Does ‘red’ refer to the same property on both sides of the biconditional? Are there two redness properties or only one?

color realism. See COLOR, QUALITIES.

combinatory logic, a branch of formal logic that deals with formal systems designed for the study of certain basic operations for constructing and manipulating functions as rules, i.e. as rules of calculation expressed by definitions.

The notion of a function was fundamental in the development of modern formal (or mathematical) logic that was initiated by Frege, Peano, Russell, Hilbert, and others. Frege was the first to introduce a generalization of the mathematical notion of a function to include propositional functions, and he used the general notion for formally representing logical notions such as those of a concept, object, relation, generality, and judgment. Frege’s proposal to replace the traditional logical notions of subject and predicate by argument and function, and thus to conceive predication as functional application, marks a turning point in the history of formal logic. In most modern logical systems, the notation used to express functions, including propositional functions, is essentially that used in ordinary mathematics. As in ordinary mathematics, certain basic notions are taken for granted, such as the use of variables to indicate processes of substitution.

Like the original systems for modern formal logic, the systems of combinatory logic were designed to give a foundation for mathematics. But combinatory logic arose as an effort to carry the foundational aims further and deeper. It undertook an analysis of notions taken for granted in the original systems, in particular of the notions of substitution and of the use of variables. In this respect combinatory logic was conceived by one of its founders, H. B. Curry, to be concerned with the ultimate foundations and with notions that constitute a “prelogic.” It was hoped that an analysis of this prelogic would disclose the true source of the difficulties connected with the logical paradoxes.

The operation of applying a function to one of its arguments, called *application*, is a primitive operation in all systems of combinatory logic. If f is a function and x a possible argument, then the result of the application operation is denoted (fx). In mathematics this is usually written $f(x)$, but the notation (fx) is more convenient in combinatory logic. The German logician M. Schönfinkel, who started combinatory logic in 1924, observed that it is not necessary to introduce functions of more than one variable, provided the idea of a function is enlarged so that functions can be arguments as well as values of other functions. A function $F(x,y)$ is represented with the function f, which when applied to the argument x has, as a value, the function (fx), which, when applied to y, yields $F(x,y)$, i.e. $((fx)y) = F(x,y)$. It is therefore convenient to omit parentheses with association to the left so that $fx_1 \ldots x_n$ is used for $((\ldots (fx_1 \ldots)x_n)$. Schönfinkel’s main result was to show how to make the class of functions studied closed under explicit definition by introducing two specific primitive functions, the *combinators* **S** and **K**, with the rules $\mathbf{K}xy = x$, and $\mathbf{S}xyz = xz(yz)$. (To illustrate the effect of **S** in ordinary mathematical notation, let *f* and *g* be functions of two and one arguments, respectively; then **S***fg* is the function such that **S***fgx* = $f(x,g(x))$.) Generally, if $a(x_1, \ldots, x_n)$ is an expression built up from constants and the variables shown by means of the application operation, then there is a function *F* constructed out of constants (including the combinators **S** and **K**), such that $Fx_1 \ldots x_n = \boldsymbol{a}(x_1, \ldots, x_n)$. This is essentially the meaning of the *combinatory completeness* of the theory of combinators in the terminology of H. B. Curry and R. Feys, *Combinatory Logic* (1958); and H. B. Curry, J. R. Hindley, and J. P. Seldin, *Combinatory Logic*, Vol. II (1972).

The system of combinatory logic with **S** and **K** as the only primitive functions is the simplest equation calculus that is essentially undecidable. It is a type-free theory that allows the formation of the term *ff*, i.e. self-application, which has given rise to problems of interpretation. There are also type theories based on combinatory logic. The systems obtained by extending the theory of combinators with functions representing more familiar logical notions such as negation, implication, and generality, or by adding a device for expressing inclusion in logical categories, are studied in *illative combinatory logic*.

The theory of combinators exists in another, equivalent form, namely as the type-free *λ-calculus* created by Church in 1932. Like the theory of combinators, it was designed as a formalism for representing functions as rules of calculation, and it was originally part of a more general system of functions intended as a foundation for mathematics. The λ-calculus has application as a primitive operation, but instead of building up new functions from some primitive ones by application, new functions are here obtained by *functional abstraction*. If $a(x)$ is an expression built up by means of application from constants and the variable *x*, then $a(x)$ is considered to define a function denoted $\lambda x.a(x)$, whose value for the argument *b* is $a(b)$, i.e. $(\lambda x.a(x))b = a(b)$. The function $\lambda x.a(x)$ is obtained from $a(x)$ by functional abstraction. The property of combinatory completeness or closure under explicit definition is postulated in the form of functional abstraction. The combinators can be defined using functional abstraction (i.e., $\mathbf{K} = \lambda x.\lambda y.x$ and $\mathbf{S} = \lambda x.\lambda y.\lambda z.xz(yz)$), and conversely, in the theory of combinators, functional abstraction can be defined. A detailed presentation of the λ-calculus is found in H. Barendregt, *The Lambda Calculus, Its Syntax and Semantics* (1981).

It is possible to represent the series of natural numbers by a sequence of closed terms in the λ-calculus. Certain expressions in the λ-calculus will then represent functions on the natural numbers, and these *λ-definable* functions are exactly the general recursive functions or the Turing computable functions. The equivalence of λ-definability and general recursiveness was one of the arguments used by Church for what is known as Church's thesis, i.e. the identification of the effectively computable functions and the recursive functions. The first problem about recursive undecidability was expressed by Church as a problem about expressions in the λ-calculus.

The λ-calculus thus played a historically important role in the original development of recursion theory. Due to the emphasis in combinatory logic on the computational aspect of functions, it is natural that its method has been found useful in proof theory and in the development of systems of constructive mathematics. For the same reason it has found several applications in computer science in the construction and analysis of programming languages. The techniques of combinatory logic have also been applied in theoretical linguistics, e.g. in so-called Montague grammar.

In recent decades combinatory logic, like other domains of mathematical logic, has developed into a specialized branch of mathematics, in which the original philosophical and foundational aims and motives are of little and often no importance. One reason for this is the discovery of the new technical applications, which were not intended originally, and which have turned the interest toward several new mathematical problems. Thus, the original motives are often felt to be less urgent and only of historical significance. Another reason for the decline of the original philosophical and foundational aims may be a growing awareness in the philosophy of mathematics of the limitations of formal and mathematical methods as tools for conceptual clarification, as tools for reaching "ultimate foundations."

command theory of law. See PHILOSOPHY OF LAW.

commentaries on Aristotle, the term commonly used for the Greek commentaries on Aristotle that take up about 15,000 pages in the Berlin *Commentaria in Aristotelem Graeca* (1882–1909), still the basic edition of them. Only in the 1980s did a project begin, under the editorship of Richard Sorabji, of King's College, London, to translate at least the most significant portions of them into English. They had remained the largest corpus of Greek philosophy not translated into any modern language.

Most of these works, especially the later, Neoplatonic ones, are much more than simple commentaries on Aristotle. They are also a mode of doing philosophy, the favored one at this stage of intellectual history. They are therefore important not only for the understanding of Aristotle, but also for both the study of the pre-Socratics and the Hellenistic philosophers, particularly the Stoics, of whom they preserve many fragments, and lastly for the study of Neoplatonism itself – and, in the case of John Philoponus, for studying the innovations he introduces in the process of trying to reconcile Platonism with Christianity.

The commentaries may be divided into three main groups.

(1) The first group of commentaries are those by Peripatetic scholars of the second to fourth centuries A.D., most notably Alexander of Aphrodisias (fl. c.200), but also the paraphraser Themistius (fl. c.360). We must not fail, however, to note Alexander's predecessor Aspasius, author of the earliest surviving commentary, one on the *Nicomachean Ethics* – a work not commented on again until the late Byzantine period. Commentaries by Alexander survive on the *Prior Analytics, Topics, Metaphysics* I–V, *On the Senses*, and *Meteorologics*, and his now lost ones on the *Categories, On the Soul*, and *Physics* had enormous influence in later times, particularly on Simplicius.

(2) By far the largest group is that of the Neoplatonists up to the sixth century A.D. Most important of the earlier commentators is Porphyry (232–c.309), of whom only a short commentary on the *Categories* survives, together with an introduction (*Isagoge*) to Aristotle's logical works, which provoked many commentaries itself, and proved most influential both in the East and (through Boethius) in the Latin West. The reconciling of Plato and Aristotle is largely his work. His big commentary on the *Categories* was of great importance in later times, and many fragments are preserved in that of Simplicius. His follower Iamblichus was also influential, but his commentaries are likewise lost. The Athenian School of Syrianus (c.375–437) and Proclus (410–85) also commented on Aristotle, but all that survives is a commentary of Syrianus on Books III, IV, XIII, and XIV of the *Metaphysics*.

It is the early sixth century, however, that produces the bulk of our surviving commentaries, originating from the Alexandrian School of Ammonius, son of Hermeias (c.435–520), but composed both in Alexandria, by the Christian John Philoponus (c.490–575), and in (or at least *from*) Athens, by Simplicius (writing after 532). Main commentaries of Philoponus are on *Categories, Prior Analytics, Posterior Analytics, On Generation and Corruption, On the Soul* I–II, and *Physics;* of Simplicius on *Categories, Physics, On the Heavens*, and (perhaps) *On the Soul*. The tradition is carried on in Alexandria by Olympiodorus (c.495–565) and the Christians Elias (fl. c.540) and David (an Armenian, nicknamed "the Invincible," fl. c.575), and finally by Stephanus, who was brought by the emperor to take the chair of philosophy in Constantinople in about 610. These scholars comment chiefly on the *Categories* and other introductory material, but Olympiodorus produced a commentary on the *Meteorologics*.

Characteristic of the Neoplatonists is a desire to reconcile Aristotle with Platonism (arguing, e.g., that Aristotle was not dismissing the Platonic theory of Forms), and to systematize his thought, thus reconciling him with himself. They are responding to a long tradition of criticism, during which difficulties were raised about incoherences and contradictions in Aristotle's thought, and they are concerned to solve these, drawing on their comprehensive knowledge of his writings. Only Philoponus, as a Christian, dares to criticize him, in particular on the eternity of the world, but also on the concept of infinity (on which he produces an ingenious argument, picked up, via the Arabs, by Bonaventure in the thirteenth century). The *Categories* proves a particularly fruitful battleground, and much of the later debate between realism and nominalism stems from arguments about the proper subject matter of that work.

The format of these commentaries is mostly that adopted by scholars ever since, that of taking one passage, or *lemma*, after another of the source work and discussing it from every angle, but there are variations. Sometimes the general subject matter is discussed first, and then details of the text are examined; alternatively, the *lemma* is taken in subdivisions without any such distinction. The commentary can also proceed explicitly by answering problems, or *aporiai*, which have been raised by previous authorities. Some commentaries, such as the short one of Porphyry on the *Categories*, and that of Iamblichus's pupil Dexippus on the same work, have a "catechetical" form, proceeding by question and answer. In some cases (as with Wittgenstein in modern times) the commentaries are simply transcriptions by pupils of the lectures of a teacher. This is the case, for example, with the surviving "commentaries" of Ammonius. One may also indulge in simple paraphrase, as does Themistius on *Posterior Analysis, Physics, On the Soul*, and *On the Heavens*, but even here a good deal of interpretation is involved, and his works remain interesting.

An important offshoot of all this activity in the Latin West is the figure of Boethius (c.480–524). It is he who first transmitted a knowledge of Aristotelian logic to the West, to become an integral part of medieval Scholasticism. He translated Porphyry's *Isagoge*, and the whole of Aristotle's logical works. He wrote a double commentary on the *Isagoge*, and commentaries on the *Categories* and *On Interpretation*. He is dependent ultimately on Porphyry, but more immediately, it would seem, on a source in the School of Proclus.

(3) The third major group of commentaries dates from the late Byzantine period, and seems mainly to emanate from a circle of scholars grouped around the princess Anna Comnena in the twelfth century. The most important figures here are Eustratius (c.1050–1120) and Michael of Ephesus (originally dated c.1040, but now fixed at c.1130). Michael in particular seems concerned to comment on areas of Aristotle's works that had hitherto escaped commentary. He therefore comments widely, e.g. on the biological works, but also on the *Sophistical Refutations*. He and Eustratius, and perhaps others, seem to have cooperated also on a composite commentary on the *Nicomachean Ethics*, neglected since Aspasius. There is also evidence of lost commentaries on the *Politics* and the *Rhetoric*.

The composite commentary on the *Ethics* was translated into Latin in the next century, in England, by Robert Grosseteste, but earlier than this translations of the various logical commentaries had been made by James of Venice (fl. c.1130), who may have even made the acquaintance of Michael of Ephesus in Constantinople. Later in that century other commentaries were being translated from Arabic versions by Gerard of Cremona (d.1187). The influence of the Greek commentary tradition in the West thus resumed after the long break since Boethius in the sixth century, but only now, it seems fair to say, is the full significance of this enormous body of work becoming properly appreciated.

See also ARISTOTLE, BOETHIUS, NEOPLATONISM, PORPHYRY. J.M.D.

commentaries on Plato, a term designating the works in the tradition of commentary (*hypomnema*) on Plato that may go back to the Old Academy (Crantor is attested by Proclus to have been the first to have "commented" on the *Timaeus*). More probably, the tradition arises in the first century B.C. in Alexandria, where we find Eudorus commenting, again, on the *Timaeus*, but possibly also (if the scholars who attribute to him the *Anonymous Theaetetus Commentary* are correct) on the *Theaetetus*. It seems also as if the Stoic Posidonius composed a commentary of some sort on the *Timaeus*. The commentary form (such as we can observe in the biblical commentaries of Philo of Alexandria) owes much to the Stoic tradition of commentary on Homer, as practiced by the second-century B.C. School of Pergamum. It was normal to select (usually consecutive) portions of text (*lemmata*) for general, and then detailed, comment, raising and answering "problems" (*aporiai*), refuting one's predecessors, and dealing with points of both doctrine and philology.

By the second century A.D. the tradition of Platonic commentary was firmly established. We have evidence of commentaries by the Middle Platonists Gaius, Albinus, Atticus, Numenius, and Cronius, mainly on the *Timaeus*, but also on at least parts of the *Republic*, as well as a work by Atticus's pupil Herpocration of Argos, in twenty-four books, on Plato's work as a whole. These works are all lost, but in the surviving works of Plutarch we find exegesis of parts of Plato's works, such as the creation of the soul in the *Timaeus* (35a–36d). The Latin commentary of Calcidius (fourth century A.D.) is also basically Middle Platonic.

In the Neoplatonic period (after Plotinus, who did not indulge in formal commentary, though many of his essays are in fact informal commentaries), we have evidence of much more comprehensive exegetic activity. Porphyry initiated the tradition with commentaries on the *Phaedo, Cratylus, Sophist, Philebus, Parmenides* (of which the surviving anonymous fragment of commentary is probably a part), and the *Timaeus*. He also commented on the myth of Er in the *Republic*. It seems to have been Porphyry who was responsible for introducing the allegorical interpretation of the introductory portions of the dialogues, though it was only his follower Iamblichus (who also commented on all the above dialogues, as well as the *Alcibiades* and the *Phaedrus*) who introduced the principle that each dialogue should have only one central theme, or *skopos*. The tradition was carried on in the Athenian School by Syrianus and his pupils Hermeias (on the *Phaedrus* – surviving) and Proclus (*Alcibiades, Cratylus, Timaeus, Parmenides* – all surviving, at least in part), and continued in later times by Damascius (*Phaedo, Philebus, Parmenides*) and Olympiodorus (*Alcibiades, Phaedo, Gorgias* – also surviving, though sometimes only in the form of pupils' notes).

These commentaries are not now to be valued primarily as expositions of Plato's thought (though they do contain useful insights, and much valuable information); they are best regarded as original philosophical treatises presented in the mode of commentary, as is so much of later Greek philosophy, where it is not originality but rather faithfulness to an inspired master and a great tradition that is being striven for.

common good, a normative standard in Thomistic and Neo-Thomistic ethics for evaluating the justice of social, legal, and political arrangements, referring to those arrangements that promote the full flourishing of everyone in the community. Every good can be regarded as both a goal to be sought and, when achieved, a source of human fulfillment. *A* common good is any good sought by and/or enjoyed by two or more persons (as friendship is a good common to the friends); *the* common good is the good of a "perfect" (i.e., complete and politically organized) human community – a good that is the common goal of all who promote the justice of that community, as well as the common source of fulfillment of all who share in those just arrangements.

'Common' is an analogical term referring to kinds and degrees of sharing ranging from mere similarity to a deep ontological communion. Thus, any good that is a genuine perfection of our common human nature is a common good, as opposed to merely idiosyncratic or illusory goods. But goods are common in a deeper sense when the degree of sharing is more than merely coincidental: two children engaged in parallel play enjoy a good in common, but they realize a common good more fully by engaging each other in one game; similarly, if each in a group watches the same good movie alone at home, they have enjoyed a good in common but they realize this good at a deeper level when they watch the movie together in a theater and discuss it afterward. In short, common good includes aggregates of private, individual goods but transcends these aggregates by the unique fulfillment afforded by mutuality, shared activity, and communion of persons.

As to the sources in Thomistic ethics for this emphasis on what is deeply shared over what merely coincides, the first is Aristotle's understanding of us as social and political animals: many aspects of human perfection, on this view, can be achieved only through shared activities in communities, especially the political community. The second is Christian Trinitarian theology, in which the single Godhead involves the mysterious communion of three divine "persons," the very exemplar of a common good; human personhood, by analogy, is similarly perfected only in a relationship of social communion.

The achievement of such intimately shared goods requires very complex and delicate arrangements of coordination to prevent the exploitation and injustice that plague shared endeavors. The establishment and maintenance of these social, legal, and political arrangements is "the" common good of a political society, because the enjoyment of all goods is so dependent upon the quality and the justice of those arrangements. The common good of the political community includes, but is not limited to, public goods: goods characterized by non-rivalry and non-excludability and which, therefore, must generally be provided by public institutions. By the principle of subsidiarity, the common good is best promoted by, in addition to the state, many lower-level non-public societies, associations, and individuals. Thus, religiously affiliated schools educating non-religious minority children might promote the common good without being public goods.

compactness. See DEDUCTION.

compactness theorem, a theorem for first-order logic: if every finite subset of a given infinite theory *T* is consistent, then the whole theory is consistent. The result is an immediate consequence of the completeness theorem, for if the theory were not consistent, a contradiction, say '*P* and not-*P*', would be provable from it. But the proof, being a finitary object, would use only finitely many axioms from *T*, so this finite subset of *T* would be inconsistent.

This proof of the compactness theorem is very general, showing that any language that has a sound and complete system of inference, where each rule allows only finitely many premises, satisfies the theorem. This is important because the theorem immediately implies that many familiar mathematical notions are not expressible in the language in question, notions like those of a finite set or a well-ordering relation.

The compactness theorem is important for other reasons as well. It is the most frequently applied result in the study of first-order model theory and has inspired interesting developments within set theory and its foundations by generating a search for infinitary languages that obey some analog of the theorem.

complementary class, the class of all things not in a given class. For example, if *C* is the class of all red things, then its complementary class is the class containing everything that is not red. This latter class includes even non-colored things, like numbers and the class *C* itself. Often, the context will determine a less inclusive complementary class. If $B \subseteq A$, then the *complement of **B** with respect to **A*** is $A - B$. For example, if *A* is the class of physical objects, and *B* is the class of red physical objects, then the complement of *B* with respect to *A* is the class of non-red physical objects. **See also** **SET THEORY.** P.Mad.

complementary term. See CONTRAPOSITION.

complementation. See NEGATION.

complete negation. See NECESSITY, PHILOSOPHY OF MIND.

completeness, a property that something – typically, a set of axioms, a logic, a theory, a set of well-formed formulas, a language, or a set of connectives – has when it is strong enough in some desirable respect.

(1) A set of axioms is *complete for the logic L* if every theorem of *L* is provable using those axioms.

(2) A logic *L* has *weak semantical completeness* if every valid sentence of the language of *L* is a theorem of *L*. *L* has *strong semantical completeness* (or is *deductively complete*) if for every set Γ of sentences, every logical consequence of Γ is deducible from Γ using *L*. A propositional logic *L* is *Halldén-complete* if whenever $A \lor B$ is a theorem of *L*, where *A* and *B* share no variables, either *A* or *B* is a theorem of *L*. And *L* is *Post-complete* if *L* is consistent but no stronger logic for the same language is consistent. Reference to the "completeness" of a logic, without further qualification, is almost invariably to either weak or strong semantical completeness. One curious exception: second-order logic is often said to be "incomplete," where what is meant is that it is not axiomatizable.

(3) A theory *T* is *negation-complete* (often simply *complete*) if for every sentence *A* of the language of *T*, either *A* or its negation is provable in *T*. And *T* is *omega-complete* if whenever it is provable in *T* that a property ϕ holds of each natural number 0, 1, . . ., it is also provable that every number has ϕ. (Generalizing on this, any set Γ of well-formed formulas might be called omega-complete if $(v)A[v]$ is deducible from Γ whenever $A[t]$ is deducible from Γ for all terms *t*, where $A[t]$ is the result of replacing all free occurrences of *v* in $A[v]$ by *t*.)

(4) A language L is *expressively complete* if each of a given class of items is expressible in L. Usually the class in question is the class of (two-valued) truth-functions. The propositional language whose sole connectives are $\sim$ and $\lor$ is thus said to be expressively (*or functionally*) complete,

while that built up using ∨ alone is not, since classical negation is not expressible therein. Here one might also say that the set {~, ∨} is expressively (or functionally) complete, while {∨} is not.

completeness theorem. See SATISFIABLE.

complete symbol. See SYNCATEGOREMATA.

complexe significabile (plural: *complexe significabilia*), also called *complexum significabile*, in medieval philosophy, what is signified only by a *complexum* (a statement or declarative sentence), by a that-clause, or by a *dictum* (an accusative + infinitive construction, as in 'I want him to go'). It is analogous to the modern proposition. The doctrine seems to have originated with Adam de Wodeham in the early fourteenth century, but is usually associated with Gregory of Rimini slightly later. *Complexe significabilia* do not fall under any of the Aristotelian categories, and so do not "exist" in the ordinary way. Still, they are somehow real. For before creation nothing existed except God, but even then God knew that the world was going to exist. The object of this knowledge cannot have been God himself (since God is necessary, but the world's existence is contingent), and yet did not "exist" before creation. Nevertheless, it was real enough to be an object of knowledge. Some authors who maintained such a view held that these entities were not only signifiable in a complex way by a statement, but were themselves complex in their inner structure; the term '*complexum significabile*' is unique to their theories. The theory of *complexe significabilia* was vehemently criticized by late medieval nominalists. **See also** ABSTRACT ENTITY, PROPOSITION. P.V.S.

compossible, capable of existing or occurring together. For example, two individuals are compossible provided the existence of one of them is compatible with the existence of the other. In terms of possible worlds, things are compossible provided there is some possible world to which all of them belong; otherwise they are incompossible. Not all possibilities are compossible. For example, the extinction of life on earth by the year 3000 is possible; so is its continuation until the year 10,000; but since it is impossible that *both* of these things should happen, they are not compossible. Leibniz held that any non-actualized possibility must be incompossible with what is actual. **See also** PRINCIPLE OF PLENITUDE. P.Mac.

comprehension, as applied to a term, the set of attributes implied by a term. The comprehension of 'square', e.g., includes being four-sided, having equal sides, and being a plane figure, among other attributes. The comprehension of a term is contrasted with its extension, which is the set of individuals to which the term applies. The distinction between the extension and the comprehension of a term was introduced in the *Port-Royal Logic* by Arnauld and Pierre Nicole in 1662. Current practice is to use the expression 'intension' rather than 'comprehension'. Both expressions, however, are inherently somewhat vague. **See also** AXIOM OF COMPREHENSION. V.K.

compresence, an unanalyzable relation in terms of which Russell, in his later writings (especially in *Human Knowledge: Its Scope and Limits*, 1948), took concrete particular objects to be analyzable. Concrete particular objects are analyzable in terms of complexes of qualities all of whose members are *compresent*. Although this relation can be defined only ostensively, Russell states that it appears in psychology as "simultaneity in one experience" and in physics as "overlapping in space-time." *Complete complexes of compresence* are complexes of qualities having the following two properties: (1) all members of the complex are compresent; (2) given anything not a member of the complex, there is at least one member of the complex with which it is not compresent. He argues that there is strong empirical evidence that no two complete complexes have all their qualities in common. Finally, space-time point-instants are analyzed as complete complexes of compresence. Concrete particulars, on the other hand, are analyzed as series of *incomplete* complexes of compresence related by certain causal laws. **See also** BUNDLE THEORY, RUSSELL. A.C.

computability, roughly, the possibility of computation on a Turing machine. The first convincing general definition, A. N. Turing's (1936), has been proved equivalent to the known plausible alternatives, so that the concept of computability is generally recognized as an absolute one. Turing's definition referred to computations by imaginary tape-processing machines that we now know to be capable of computing the same functions (whether simple sums and products or highly complex, esoteric functions) that modern digital computing machines could compute if provided with sufficient storage capacity. In the form 'Any function that is computable at all is computable on a Turing machine', this absoluteness claim is called *Turing's thesis*. A comparable claim for Alonzo Church's (1935) concept of ***X***-computability is called *Church's thesis*. Similar theses are enunciated for Markov algorithms, for S. C. Kleene's notion of general recursiveness, etc. It has been proved that the same functions are computable in all of these ways. There is no hope of proving any of those theses, for such a proof would require a definition of 'computable' – a definition that would simply be a further item in the list, the subject of a further thesis. But since computations of new kinds might be recognizable as genuine *in particular cases*, Turing's thesis and its equivalents, if false, might be decisively refuted by discovery of a particular function, a way of computing it, and a proof that no Turing machine can compute it.

The *halting problem* for (say) Turing machines is the problem of devising a Turing machine that computes the function $h(m, n) = 1$ or 0 depending on whether or not Turing machine number m ever halts, once started with the number n on its tape. This problem is unsolvable, for a machine that computed h could be modified to compute a function $g(n)$, which is undefined (the machine goes into an endless loop) when $h(n, n) = 1$, and otherwise agrees with $h(n, n)$. But this modified machine – Turing machine number k, say – would have contradictory properties: started with k on its tape, it would eventually halt if and only if it does not. Turing proved unsolvability of the *decision problem* for logic (the problem of devising a Turing machine that, applied to argument number n in logical notation, correctly classifies it as valid or invalid) by *reducing* the halting problem to the decision problem – i.e., showing how any solution to the latter could be used to solve the former problem, which we know to be unsolvable.

computer art, artworks that (1) are made through the use of computer technology and (2) can be fully appreciated only in ways that take into account their being so made. Since computers are general-purpose devices, they are widely used in making art that does not fit this definition. Novels are routinely written on word processors, and music is often recorded and distributed digitally, but knowing these facts about the making of an artwork makes no difference to its appreciation. Genres of computer art correspond to distinct aspects of computer technology. Digital computers store and transmit data encoded as discrete symbols from a finite set, and data encoded in this way are easily manipulated. The fact that a sequence of sounds in a song is digitally sampled may affect how it is to be appreciated – as an homage, for example. Knowing that Frank Gehry designed the Guggenheim Museum in Bilboa with a CAD (computer-aided design) system created to engineer fighter jets brings out the coherence underlying an otherwise fanciful assemblage. These are cases of digital computer art. However, not all computers are digital; technically, a computer is a device designed to implement a computational process or algorithm. A computational process is one that, by a finite sequence of well-defined steps, outputs some data given some input data. (This is an abstraction of the everyday concept of a software application because different code may implement the same computational process.)

Interactive computer artworks take advantage of computational processing to output a plastic, sonic, or linguistic display based on user inputs. Computer games may be the popular take on "high art" interactive computer works. Works of genetic computer art take advantage of a class of algorithms that model the process of natural evolution through selection. In these works, an initial display seeds a next generation; a subset of this generation is selected by some input mechanism; this selection provides materials for the next generation; and the cycle repeats. The changing displays of these works cannot be foreseen by their designers and may be engaging when viewed as self-evolving forms.

Close cousins of genetic algorithms are learning algorithms, and some computer artworks are the original products of artificial intelligence artists. Once David Cope's EMI (Experiments in Musical Intelligence) has been taught the oeuvre of a classical composer, it is able to write new music in the same style, sometimes passing the Turing test by fooling musical experts trying to ascertain its genesis by listening alone.

computer modeling. See COMPUTER THEORY.

computer program. See COMPUTER THEORY.

computer theory, the theory of the design, uses, powers, and limits of modern electronic digital computers. It has important bearings on philosophy, as may be seen from the many philosophical references herein.

Modern computers are a radically new kind of machine, for they are active physical realizations of formal languages of logic and arithmetic. Computers employ sophisticated languages, and they have reasoning powers many orders of magnitude greater than those of any prior machines. Because they are far superior to humans in many important tasks, they have produced a revolution in society that is as profound as the industrial revolution and is advancing much more rapidly. Furthermore, computers themselves are evolving rapidly.

When a computer is augmented with devices for sensing and acting, it becomes a powerful control system, or a robot. To understand the implications of computers for philosophy, one should imagine a robot that has basic goals and volitions built into it, including conflicting goals and competing desires. This concept first appeared in Karel Čapek's play *Rossum's Universal Robots* (1920), where the word 'robot' originated.

A computer has two aspects, *hardware* and *programming languages*. The theory of each is relevant to philosophy. The software and hardware aspects of a computer are somewhat analogous to the human mind and body. This analogy is especially strong if we follow Peirce and consider all information processing in nature and in human organisms, not just the conscious use of language. Evolution has produced a succession of levels of sign usage and information processing: self-copying chemicals, self-reproducing cells, genetic programs directing the production of organic forms, chemical and neuronal signals in organisms, unconscious human information processing, ordinary languages, and technical languages. But each level evolved gradually from its predecessors, so that the line between body and mind is vague.

The hardware of a computer is typically organized into three general blocks: *memory, processor* (arithmetic unit and control), and various *input-output* devices for communication between machine and environment. The memory stores the *data* to be processed as well as the *program* that directs the processing. The processor has an *arithmetic-logic unit* for transforming data, and a *control* for executing the program. Memory, processor, and input-output communicate to each other through a fast switching system.

The memory and processor are constructed from registers, adders, switches, cables, and various other building blocks. These in turn are composed of electronic components: transistors, resistors, and wires. The input and output devices employ mechanical and electromechanical technologies as well as electronics. Some input-output devices also serve as auxiliary memories; floppy disks and magnetic tapes are examples. For theoretical purposes it is useful to imagine that the computer has an indefinitely expandable storage tape. So imagined, a computer is a physical realization of a Turing machine. The idea of an indefinitely expandable memory is similar to the logician's concept of an axiomatic formal language that has an unlimited number of proofs and theorems.

The software of a modern electronic computer is written in a hierarchy of programming languages. The higher-level languages are designed for use by human programmers, operators, and maintenance personnel. The "machine language" is the basic hardware language, interpreted and executed by the control. Its words are sequences of binary digits, or *bits*. Programs written in intermediate-level languages are used by the computer to translate the languages employed by human users into the machine language for execution.

A *programming language* has instructional means for carrying out three kinds of operations: data operations and transfers, transfers of control from one part of the program to the other, and program self-modification. Von Neumann designed the first modern programming language. A programming language is general purpose, and an electronic computer that executes it can in principle carry out any algorithm or effective procedure, including the simulation of any other computer. Thus the modern electronic computer is a practical realization of the abstract concept of a universal Turing machine. What can actually be computed in practice depends, of course, on the state of computer technology and its resources.

It is common for computers at many different spatial locations to be interconnected into complex networks by telephone, radio, and satellite communication systems. Insofar as users in one part of the network can control other parts, either legitimately or illegitimately (e.g., by means of a "computer virus"), a global network of computers is really a global computer. Such vast computers greatly increase societal interdependence, a fact of importance for social philosophy. The theory of computers has two branches, corresponding to the hardware and software aspects of computers.

The fundamental concept of hardware theory is that of a *finite automaton*, which may be expressed either as an idealized logical network of simple computer primitives or as the corresponding temporal system of input, output, and internal states. A finite automaton may be specified as a logical net of truth-functional switches and simple memory elements, connected to one another by idealized wires. These elements function synchronously, each wire being in a binary state (0 or 1) at each moment of time $t = 0, 1, 2, \ldots$. Each switching element (or "gate") executes a simple truth-functional operation (not, or, and, nor, not-and, etc.) and is imagined to operate instantaneously (compare the notions of sentential connective and truth table). A memory element (flip-flop, binary counter, unit delay line) preserves its input bit for one or more time-steps.

A well-formed net of switches and memory elements may not have cycles through switches only, but it typically has feedback cycles through memory elements. The wires of a logical net are of three kinds: input, internal, and output. Correspondingly, at each moment of time a logical net has an input state, an internal state, and an output state. A logical net or automaton need not have any input wires, in which case it is a closed system.

The complete history of a logical net is described by a deterministic law: at each moment of time *t*, the input and internal states of the net determine its output state and its next internal state. This leads to the second definition of 'finite automaton': it is a deterministic finite-state system characterized by two tables. The transition table gives the next internal state produced by each pair of input and internal states. The output table gives the output state produced by each input state and internal state.

The state analysis approach to computer hardware is of practical value only for systems with a few elements (e.g., a binary-coded decimal counter), because the number of states increases as a *power* of the number of elements. Such a rapid rate of increase of complexity with size is called the combinatorial explosion, and it applies to many discrete systems. However, the state approach to finite automata does yield abstract models of law-governed systems that are of interest to logic and philosophy. A correctly operating digital computer is a finite automaton. Alan Turing defined the finite part of what we now call a Turing machine in terms of states. It seems doubtful that a human organism has more computing power than a finite automaton.

A closed finite automaton illustrates Nietzsche's law of eternal return. Since a finite automaton has a finite number of internal states, at least one of its internal states must occur infinitely many times in any infinite state history. And since a closed finite automaton is deterministic and has no inputs, a repeated state must be followed by the same sequence of states each time it occurs. Hence the history of a closed finite automaton is periodic, as in the law of eternal return.

Idealized neurons are sometimes used as the primitive elements of logical nets, and it is plausible that for any brain and central nervous system there is a logical network that behaves the same and performs the same functions. This shows the close relation of finite automata to the brain and central nervous system. The switches and memory elements of a finite automaton may be made probabilistic, yielding a *probabilistic automaton*. These automata are models of indeterministic systems. Von Neumann showed how to extend deterministic logical nets to systems that contain self-reproducing automata. This is a very basic logical design relevant to the nature of life.

The part of computer programming theory most relevant to philosophy contains the answer to Leibniz's conjecture concerning his *characteristica* *universalis* and calculus ratiocinator. He held that "all our reasoning is nothing but the joining and substitution of characters, whether these characters be words or symbols or pictures." He thought therefore that one could construct a universal, arithmetic language with two properties of great philosophical importance. First, every atomic concept would be represented by a prime number. Second, the truth-value of any logically true-or-false statement expressed in the *characteristica universalis* could be calculated arithmetically, and so any rational dispute could be resolved by calculation. Leibniz expected to do the computation by hand with the help of a calculating machine; today we would do it on an electronic computer. However, we know now that Leibniz's proposed language cannot exist, for no computer (or computer program) can calculate the truth-value of every logically true-or-false statement given to it. This fact follows from a logical theorem about the limits of what computer programs can do. Let *E* be a modern electronic computer with an indefinitely expandable memory, so that *E* has the power of a universal Turing machine. And let *L* be any formal language in which every arithmetic statement can be expressed, and which is consistent. Leibniz's proposed *characteristica universalis* would be such a language. Now a computer that is operating correctly is an active formal language, carrying out the instructions of its program deductively. Accordingly, Gödel's incompleteness theorems for formal arithmetic apply to computer *E*. It follows from these theorems that no program can enable computer *E* to decide of an arbitrary statement of *L* whether or not that statement is true. More strongly, there cannot even be a program that will enable *E* to enumerate the truths of language *L* one after another. Therefore Leibniz's *characteristica universalis* cannot exist.

Electronic computers are the first active or "live" mathematical systems. They are the latest addition to a long historical series of mathematical tools for inquiry: geometry, algebra, calculus and differential equations, probability and statistics, and modern mathematics. The most effective use of computer programs is to instruct computers in tasks for which they are superior to humans. Computers are being designed and programmed to cooperate with humans so that the calculation, storage, and judgment capabilities of the two are synthesized. The powers of such *human-computer combines* will increase at an exponential rate as computers continue to become faster, more powerful, and easier to use, while at the same time becoming smaller and cheaper. The social implications of this are very important.

The modern electronic computer is a new tool for the logic of discovery (Peirce's abduction). An inquirer (or inquirers) operating a computer interactively can use it as a *universal simulator*, dynamically modeling systems that are too complex to study by traditional mathematical methods, including non-linear systems. Simulation is used to explain known empirical results, and also to develop new hypotheses to be tested by observation. Computer models and simulations are unique in several ways: complexity, dynamism, controllability, and visual presentability. These properties make them important new tools for modeling and thereby relevant to some important philosophical problems.

A human-computer combine is especially suited for the study of complex holistic and hierarchical systems with feedback (cf. cybernetics), including adaptive goal-directed systems. A hierarchical feedback system is a dynamic structure organized into several levels, with the compounds of one level being the atoms or building blocks of the next higher level, and with cyclic paths of influence operating both on and between levels. For example, a complex human institution has several levels, and the people in it are themselves hierarchical organizations of self-copying chemicals, cells, organs, and such systems as the pulmonary and the central nervous system.

The behaviors of these systems are in general much more complex than, e.g., the behaviors of traditional systems of mechanics. Contrast an organism, society, or ecology with our planetary system as characterized by Kepler and Newton. Simple formulas (ellipses) describe the orbits of the planets. More basically, the planetary system is stable in the sense that a small perturbation of it produces a relatively small variation in its subsequent history. In contrast, a small change in the state of a holistic hierarchical feedback system often amplifies into a very large difference in behavior, a concern of *chaos theory*. For this reason it is helpful to model such systems on a computer and run sample histories. The operator searches for representative cases, interesting phenomena, and general principles of operation.

The human-computer method of inquiry should be a useful tool for the study of biological evolution, the actual historical development of complex adaptive goal-directed systems. Evolution is a logical and communication process as well as a physical and chemical process. But evolution is statistical rather than deterministic, because a single temporal state of the system results in a probabilistic distribution of histories, rather than in a single history. The genetic operators of mutation and crossover, e.g., are probabilistic operators. But though it is stochastic, evolution cannot be understood in terms of limiting relative frequencies, for the important developments are the repeated emergence of new phenomena, and there may be no evolutionary convergence toward a final state or limit. Rather, to understand evolution the investigator must simulate the statistical spectra of histories covering critical stages of the process.

Many important evolutionary phenomena should be studied by using simulation along with observation and experiment. Evolution has produced a succession of levels of organization: self-copying chemicals, self-reproducing cells, communities of cells, simple organisms, haploid sexual reproduction, diploid sexuality with genetic dominance and recessiveness, organisms composed of organs, societies of organisms, humans, and societies of humans. Most of these systems are complex hierarchical feedback systems, and it is of interest to understand how they emerged from earlier systems. Also, the interaction of competition and cooperation at all stages of evolution is an important subject, of relevance to social philosophy and ethics.

Some basic epistemological and metaphysical concepts enter into computer modeling. A *model* is a well-developed concept of its object, representing characteristics like structure and function. A model is similar to its object in important respects, but simpler; in mathematical terminology, a model is homomorphic to its object but not isomorphic to it. However, it is often useful to think of a model as isomorphic to an *embedded subsystem* of the system it models. For example, a gas is a complicated system of microstates of particles, but these microstates can be grouped into macrostates, each with a pressure, volume, and temperature satisfying the gas law $PV = kT$. The derivation of this law from the detailed mechanics of the gas is a *reduction* of the embedded subsystem to the underlying system. In many cases it is adequate to work with the simpler embedded subsystem, but in other cases one must work with the more complex but complete *underlying system*.

The law of an embedded subsystem may be different in kind from the law of the underlying system. Consider, e.g., a machine tossing a coin randomly. The sequence of tosses obeys a simple probability law, while the complex underlying mechanical system is deterministic. The random sequence of tosses is a probabilistic system embedded in a deterministic system, and a mathematical account of this embedding relation constitutes a reduction of the probabilistic system to a deterministic system. Compare the compatibilist's claim that free choice can be embedded in a deterministic system. Compare also a *pseudorandom* sequence, which is a deterministic sequence with adequate randomness for a given (finite) simulation. Note finally that the probabilistic system of quantum mechanics underlies the deterministic system of mechanics.

The ways in which models are used by goal-directed systems to solve problems and adapt to their environments are currently being modeled by human-computer combines. Since computer software can be converted into hardware, successful simulations of adaptive uses of models could be incorporated into the design of a robot. Human intentionality involves the use of a model of oneself in relation to others and the environment. A problem-solving robot using such a model would constitute an important step toward a robot with full human powers.

These considerations lead to the central thesis of the *philosophy of logical mechanism:* a finite deterministic automaton can perform all human functions. This seems plausible in principle (and is treated in detail in Merrilee Salmon, ed., *The Philosophy of Logical Mechanism: Essays in Honor of Arthur W. Burks*, 1990). A digital computer has reasoning and memory powers. Robots have sensory inputs for collecting information from the environment, and they have moving and acting devices. To obtain a robot with human powers, one would need to put these abilities under the direction of a system of desires, purposes, and goals. Logical mechanism is a form of mechanism or materialism, but differs from traditional forms of these doctrines in its reliance on the logical powers of computers and the logical nature of evolution and its products. The modern computer is a kind of complex hierarchical physical system, a system with memory, processor, and control that employs a hierarchy of programming languages. Humans are complex hierarchical systems designed by evolution – with structural levels of chemicals, cells, organs, and systems (e.g., circulatory, neural, immune) and linguistic levels of genes, enzymes, neural signals, and immune recognition. Traditional materialists did not have this model of a computer or the contemporary understanding of evolution, and never gave an adequate account of logic and reasoning and such phenomena as goal-directedness and self-modeling.

Comte, Auguste (1798–1857), French philosopher and sociologist, the founder of positivism. He was educated in Paris at l'École Polytechnique, where he briefly taught mathematics. He suffered from a mental illness that occasionally interrupted his work.

In conformity with empiricism, Comte held that knowledge of the world arises from observation. He went beyond many empiricists, however, in denying the possibility of knowledge of unobservable physical objects. He conceived of positivism as a method of study based on observation and restricted to the observable. He applied positivism chiefly to science. He claimed that the goal of science is prediction, to be accomplished using laws of succession. Explanation insofar as attainable has the same structure as prediction. It subsumes events under laws of succession; it is not causal. Influenced by Kant, he held that the causes of phenomena and the nature of things-in-themselves are not knowable. He criticized metaphysics for ungrounded speculation about such matters; he accused it of not keeping imagination subordinate to observation. He advanced positivism for all the sciences but held that each science has additional special methods, and has laws not derivable by human intelligence from laws of other sciences. He corresponded extensively with J. S. Mill, who encouraged his work and discussed it in *Auguste Comte and Positivism* (1865). Twentieth-century logical positivism was inspired by Comte's ideas.

Comte was a founder of sociology, which he also called social physics. He divided the science into two branches – statics and dynamics – dealing respectively with social organization and social development. He advocated a historical method of study for both branches. As a law of social development, he proposed that all societies pass through three intellectual stages, first interpreting phenomena theologically, then metaphysically, and finally positivistically. The general idea that societies develop according to laws of nature was adopted by Marx. Comte's most important work is his six-volume *Cours de philosophie positive* ("Course in Positive Philosophy," 1830–42). It is an encyclopedic treatment of the sciences that expounds positivism and culminates in the introduction of sociology.

conative. See VOLITION.

conceivability, capability of being conceived or imagined. Thus, golden mountains are conceivable; round squares, inconceivable. As Descartes pointed out, the sort of imaginability required is not the ability to form mental images. Chiliagons, Cartesian minds, and God are all conceivable, though none of these can be pictured "in the mind's eye." Historical references include Anselm's definition of God as "a being than which none greater can be conceived" and Descartes's argument for dualism from the conceivability of disembodied existence. Several of Hume's arguments rest upon the maxim that whatever is conceivable is possible. He argued, e.g., that an event can occur without a cause, since this is conceivable, and his critique of induction relies on the inference from the conceivability of a change in the course of nature to its possibility. In response, Reid maintained that to conceive is merely to understand the meaning of a proposition. Reid argued that impossibilities are conceivable, since we must be able to understand falsehoods. Many simply equate conceivability with possibility, so that to say something is conceivable (or inconceivable) just is to say that it is possible (or impossible). Such usage is controversial, since conceivability is broadly an epistemological notion concerning what can be thought, whereas possibility is a metaphysical notion concerning how things can be.

The same controversy can arise regarding the compossible, or co-possible, where two states of affairs are compossible provided it is possible that they both obtain, and two propositions are compossible provided their conjunction is possible. Alternatively, two things are compossible if and only if there is a possible world containing both. Leibniz held that two things are compossible provided they can be ascribed to the same possible world without contradiction. "There are many possible universes, each collection of compossibles making one of them." Others have argued that non-contradiction is sufficient for neither possibility nor compossibility.

The claim that something is inconceivable is usually meant to suggest more than merely an inability to conceive. It is to say that trying to conceive results in a phenomenally distinctive mental repugnance, e.g. when one attempts to conceive of an object that is red and green all over at once. On this usage the inconceivable might be equated with what one can "just see" to be impossible. There are two related usages of 'conceivable': (1) not inconceivable in the sense just described; and (2) such that one can "just see" that the thing in question is possible. Goldbach's conjecture would seem a clear example of something conceivable in the first sense, but not the second.

conceptual immediacy. See IMMEDIACY.

conceptualism, the view that there are no universals and that the supposed classificatory function of universals is actually served by particular *concepts* in the mind. A universal is a property that can be instantiated by more than one individual thing (or particular) at the same time; e.g., the shape of this page, if identical with the shape of the next page, will be one property instantiated by two distinct individual things at the same time. If viewed as located where the pages are, then it would be *immanent*. If viewed as not having spatiotemporal location itself, but only bearing a connection, usually called *instantiation* or *exemplification*, to things that have such location, then the shape of this page would be *transcendent* and presumably would exist even if exemplified by nothing, as Plato seems to have held. The conceptualist rejects both views by holding that universal are merely concepts. Most generally, a concept may be understood as a principle of classification, something that can guide us in determining whether an entity belongs in a given class or does not. Of course, properties understood as universals satisfy, trivially, this definition and thus may be called concepts, as indeed they were by Frege. But the conceptualistic substantive views of concepts are that concepts are (1) *mental representations*, often called *ideas*, serving their classificatory function presumably by resembling the entities to be classified; or (2) brain states that serve the same function but presumably not by resemblance; or (3) general words (adjectives, common nouns, verbs) or uses of such words, an entity's belonging to a certain class being determined by the applicability to the entity of the appropriate word; or (4) abilities to classify correctly, whether or not with the aid of an item belonging under (1), (2), or (3). The traditional conceptualist holds (1). Defenders of (3) would be more properly called nominalists. In whichever way concepts are understood, and regardless of whether conceptualism is true, they are obviously essential to our understanding and knowledge of anything, even at the most basic level of cognition, namely recognition. The classic work on the topic is *Thinking and Experience* (1954) by H. H. Price, who held (4). **See also** METAPHYSICS, PLATO, PROPERTY. P.Bu.

concursus dei, God's concurrence. The notion derives from a theory from medieval philosophical theology, according to which any case of causation involving created substances requires both the exercise of genuine causal powers inherent in creatures and the exercise of God's causal activity. In particular, a person's actions are the result of the person's causal powers, often including the powers of deliberation and choice, and God's causal endorsement. Divine concurrence maintains that the nature of God's activity is more determinate than simply conserving the created world in existence. Although divine concurrence agrees with occasionalism in holding God's power to be necessary for any event to occur, it diverges from occasionalism insofar as it regards creatures as causally active. **See also** OCCASIONALISM. W.E.M.

Condillac, Étienne Bonnot de (1714–80), French philosopher, an empiricist who was considered the great analytical mind of his generation. Close to Rousseau and Diderot, he stayed within the church. He is closely (perhaps excessively) identified with the image of the statue that, in the *Traité des sensations* ("Treatise on Sense Perception," 1754), he endows with the five senses to explain how perceptions are assimilated and produce understanding (cf. his *Treatise on the Origins of Human Knowledge*, 1746). He maintains a critical distance from precursors: he adopts Locke's *tabula rasa* but from his first work to *Logique* ("Logic," 1780) insists on the creative role of the mind as it analyzes and compares sense impressions. His *Traité des animaux* ("Treatise on Animals," 1755), which includes a proof of the existence of God, considers sensate creatures rather than Descartes's *animaux machines* and sees God only as a final cause. He reshapes Leibniz's monads in the *Monadologie* ("Monadology," 1748, rediscovered in 1980). In the *Langue des calculs* ("Language of Numbers," 1798) he proposes mathematics as a model of clear analysis.

The origin of language and creation of symbols eventually became his major concern. His break with metaphysics in the *Traité des systèmes* ("Treatise on Systems," 1749) has been overemphasized, but Condillac does replace rational constructs with sense experience and reflection. His empiricism has been mistaken for materialism, his clear analysis for simplicity. The "ideologues," Destutt de Tracy and Laromiguière, found Locke in his writings. Jefferson admired him. Maine de Biran, while critical, was indebted to him for concepts of perception and the self; Cousin disliked him; Saussure saw him as a forerunner in the study of the origins of language.

See also FRENCH PHILOSOPHY, LEIBNIZ, LOCKE, SENSATIONALISM. O.A.H.

condition, a state of affairs or "way things are," most commonly referred to in relation to something that implies or is implied by it. Let *p*, *q*, and *r* be schematic letters for declarative sentences; and let *P*, *Q*, and *R* be corresponding nominalizations; e.g., if *p* is 'Snow is white', then *P* would be 'snow's being white'. *P* can be a necessary or sufficient condition of *Q* in any of several senses. In the weakest sense *P* is a sufficient condition of *Q* iff (if and only if): if *p* then *q* (or if *P* is actual then *Q* is actual) – where the conditional is to be read as 'material', as amounting merely to not-(*p* & not-*q*). At the same time *Q* is a necessary condition of *P* iff: if not-*q* then not-*p*. It follows that *P* is a sufficient condition of *Q* iff *Q* is a necessary condition of *P*. Stronger senses of sufficiency and of necessity are definable, in terms of this basic sense, as follows: *P* is *nomologically sufficient* (necessary) for *Q* iff it follows from the laws of nature, but not without them, that if *p* then *q* (that if *q* then *p*). *P* is *alethically or metaphysically* sufficient (necessary) for *Q* iff it is alethically or metaphysically necessary that if *p* then *q* (that if *q* then *p*). However, it is perhaps most common of all to interpret conditions in terms of subjunctive conditionals, in such a way that *P* is a sufficient condition of *Q* iff *P* would not occur unless *Q* occurred, or: if *P* should occur, *Q* would; and *P* is a necessary condition of *Q* iff *Q* would not occur unless *P* occurred, or: if *Q* should occur, *P* would. **See also** CAUSATION, PROPERTY, STATE OF AFFAIRS. E.S.

conditional, a compound sentence, such as 'If Abe calls, then Ben answers', in which one sentence, the antecedent, is connected to a second, the consequent, by the connective 'if . . . then'. Propositions (statements, etc.) expressed by conditionals are called *conditional propositions* (*statements*, etc.) and, by ellipsis, simply *conditionals*. The ambiguity of the expression 'if . . . then' gives rise to a semantic classification of conditionals into material conditionals, causal conditionals, counterfactual conditionals, etc. In traditional logic, conditionals are called *hypotheticals*, and in some areas of mathematical logic conditionals are called implications. Faithful analysis of the meanings of conditionals continues to be sought and disputed. **See also** CORRESPONDING CONDITIONAL, COUNTERFACTUALS, IMPLICATION, PROPOSITION, TRUTH TABLE. J.Cor.

conditional, strict. See COUNTERFACTUALS, IMPLICATION.

conditionalization, the process by which a rational epistemic agent updates credences in response to evidence. In Bayesian epistemology, an agent's epistemic state is represented by the *degrees of belief*, or *credences*, the agent assigns to propositions. An epistemic agent assigns "unconditional" credences to propositions as well as "conditional" credences of the form $\mathrm{Cr}(p \mid q)$, which is to be read as 'credence in p given q'. One's conditional credences are related to one's unconditional credences by the following formula: $\mathrm{Cr}(p \,\&\, q) = \mathrm{Cr}(q)\mathrm{Cr}(p \mid q)$. Another formula that governs conditional and unconditional credences, derivable from the previous formula and the remaining axioms of the probability calculus, is Bayes's rule.

Traditionally, learning new evidence E is represented by becoming certain of E, i.e. by assigning $\mathrm{Cr}(E) = 1$. One then forms new credences using one's old conditional credences, conditional on the new evidence E: $\mathrm{Cr}_{\mathrm{new}}(H) = \mathrm{Cr}_{\mathrm{old}}(H \mid E)$. This belief-updating process is known as conditionalization.

conditional proof. (1) The argument form '*B* follows from *A*; therefore, if *A* then *B*' and arguments of this form. (2) The rule of inference that permits one to infer a conditional given a derivation of its consequent from its antecedent. This is also known as the *rule of conditional proof* or $\supset$-*introduction*. See DEDUCTION, DEDUCTION THEOREM, PROOF. G.F.S.

conditional proposition. See CONDITIONAL, CONVERSE, COUNTERFACTUALS.

conditioning, a form of associative learning that occurs when changes in thought or behavior are produced by temporal relations among events. It is common to distinguish between two types of conditioning; one, *classical* or Pavlovian, in which behavior change results from events that occur before behavior; the other, *operant* or instrumental, in which behavior change occurs because of events after behavior. Roughly, classically conditioned behavior and operantly conditioned behavior correspond to the everyday, folk-psychological distinction between involuntary and voluntary or goal-directed behavior. In classical conditioning, stimuli or events elicit a response (e.g., salivation); neutral stimuli (e.g., a dinner bell) gain control over behavior when paired with stimuli that already elicit behavior (e.g., the appearance of dinner). The behavior is involuntary. In operant conditioning, stimuli or events reinforce behavior after behavior occurs; neutral stimuli gain power to reinforce by being paired with actual reinforcers. Here, occasions in which behavior is reinforced serve as discriminative stimuli-evoking behavior. Operant behavior is goal-directed, if not consciously or deliberately, then through the bond between behavior and reinforcement. Thus, the arrangement of condiments at dinner may serve as the discriminative stimulus evoking the request "Please pass the salt," whereas saying "Thank you" may reinforce the behavior of passing the salt.

It is not easy to integrate conditioning phenomena into a unified theory of conditioning. Some theorists contend that operant conditioning is really classical conditioning veiled by subtle temporal relations among events. Other theorists contend that operant conditioning requires mental representations of reinforcers and discriminative stimuli. B. F. Skinner (1904–90) argued in *Walden Two* (1948) that astute, benevolent behavioral engineers can and should use conditioning to create a social utopia.

See also REDINTEGRATION. G.A.G.

conditio sine qua non (Latin, 'a condition without which not'), a necessary condition; something without which something else could not be or could not occur. For example, being a plane figure is a *conditio sine qua non* for being a triangle. Sometimes the phrase is used emphatically as a synonym for an unconditioned presupposition, be it for an action to start or an argument to get going. I.Bo.

Condorcet, Marquis de, title of Marie-Jean-Antoine-Nicolas de Caritat (1743–94), French philosopher and political theorist who contributed to the *Encyclopedia* and pioneered the mathematical analysis of social institutions. Although prominent in the Revolutionary government, he was denounced for his political views and died in prison.

Condorcet discovered the voting paradox, which shows that majoritarian voting can produce cyclical group preferences. Suppose, e.g., that voters A, B, and C rank proposals *x*, *y*, and *z* as follows: A: *xyz*, B: *yzx*, and C: *zxy*. Then in majoritarian voting *x* beats *y* and *y* beats *z*, but *z* in turn beats *x*. So the resulting group preferences are cyclical. The discovery of this problem helped initiate social choice theory, which evaluates voting systems. Condorcet argued that any satisfactory voting system must guarantee selection of a proposal that beats all rivals in majoritarian competition. Such a proposal is called a *Condorcet winner*. His *jury theorem* says that if voters register their opinions about some matter, such as whether a defendant is guilty, and the probabilities that individual voters are right are greater than ½, equal, and independent, then the majority vote is more likely to be correct than any individual's or minority's vote.

Condorcet's main works are *Essai sur l'application de l'analyse à la probabilité des décisions rendues à la pluralité des voix* ("Essay on the Application of Analysis to the Probability of Decisions Reached by a Majority of Votes," 1785); and a posthumous treatise on social issues, *Esquisse d'un tableau historique des progrès de l'esprit humain* ("Sketch for a Historical Picture of the Progress of the Human Mind," 1795).

See also PROBABILITY, SOCIAL CHOICE THEORY, VOTING PARADOX. P.We.

Condorcet winner. See CONDORCET.

confirmation, an evidential relation between evidence and any statement (especially a scientific hypothesis) that this evidence supports. It is essential to distinguish two distinct, and fundamentally different, meanings of the term: (1) the *incremental* sense, in which a piece of evidence contributes at least some degree of support to the hypothesis in question – e.g., finding a fingerprint of the suspect at the scene of the crime lends some weight to the hypothesis that the suspect is guilty; and (2) the *absolute* sense, in which a body of evidence provides strong support for the hypothesis in question – e.g., a case presented by a prosecutor making it practically certain that the suspect is guilty. If one thinks of confirmation in terms of probability, then evidence that *increases* the probability of a hypothesis confirms it incrementally, whereas evidence that renders a hypothesis *highly probable* confirms it absolutely.

In each of the two foregoing senses one can distinguish three types of confirmation: (i) *qualitative*, (ii) *quantitative*, and (iii) *comparative*. (i) Both examples in the preceding paragraph illustrate qualitative confirmation, for no numerical values of the degree of confirmation were mentioned. (ii) If a gambler, upon learning that an opponent holds a certain card, asserts that her chance of winning has increased from ⅔ to ¾, the claim is an instance of quantitative incremental confirmation. If a physician states that, on the basis of an X-ray, the probability that the patient has tuberculosis is .95, that claim exemplifies quantitative absolute confirmation. In the incremental sense, any case of quantitative confirmation involves a *difference* between two probability values; in the absolute sense, any case of quantitative confirmation involves *only one* probability value. (iii) Comparative confirmation in the incremental sense would be illustrated if an investigator said that possession of the murder weapon weighs more heavily against the suspect than does the fingerprint found at the scene of the crime. Comparative confirmation in the absolute sense would occur if a prosecutor claimed to have strong cases against two suspects thought to be involved in a crime, but that the case against one is stronger than that against the other.

Even given recognition of the foregoing six varieties of confirmation, there is still considerable controversy regarding its analysis. Some authors claim that quantitative confirmation does not exist; only qualitative and/or comparative confirmation are possible. Some authors maintain that confirmation has nothing to do with probability, whereas others – known as Bayesians – analyze confirmation explicitly in terms of Bayes's theorem in the mathematical calculus of probability. Among those who offer probabilistic analyses there are differences as to which interpretation of probability is suitable in this context. Popper advocates a concept of corroboration that differs fundamentally from confirmation.

Many (real or apparent) paradoxes of confirmation have been posed; the most famous is the *paradox of the ravens*. It is plausible to suppose that 'All ravens are black' can be incrementally confirmed by the observation of one of its instances, namely, a black crow. However, 'All ravens are black' is logically equivalent to 'All non-black things are non-ravens'. By parity of reasoning, an instance of this statement, namely any non-black non-raven (e.g., a white shoe), should incrementally confirm it. Moreover, the *equivalence condition* – whatever confirms a hypothesis must equally confirm any statement logically equivalent to it – seems eminently reasonable. The result appears to facilitate indoor ornithology, for the observation of a white shoe would seem to confirm incrementally the hypothesis that all ravens are black. Many attempted resolutions of this paradox can be found in the literature.

Confucianism, a Chinese school of thought and set of moral, ethical, and political teachings usually considered to be founded by Confucius. Before the time of Confucius (sixth–fifth century B.C.), a social group, the *Ru* (literally, 'weaklings' or 'foundlings'), existed whose members were ritualists and sometimes also teachers by profession. Confucius belonged to this group; but although he retained the interest in rituals, he was also concerned with the then chaotic social and political situation and with the search for remedies, which he believed to lie in the restoration and maintenance of certain traditional values and norms. Later thinkers who professed to be followers of Confucius shared such concern and belief and, although they interpreted and developed Confucius's teachings in different ways, they are often regarded as belonging to the same school of thought, traditionally referred to by Chinese scholars as *Rujia*, or the school of the *Ru*. The term 'Confucianism' is used to refer to some or all of the range of phenomena, including the way of life of the *Ru* as a group of ritualists, the school of thought referred to as *Rujia*, the ethical, social, and political ideals advocated by this school of thought (which include but go well beyond the practice of rituals), and the influence of such ideals on the actual social and political order and the life of the Chinese.

As a school of thought, Confucianism is characterized by a common ethical ideal which includes an affective concern for all living things, varying in degree and nature depending on how such things relate to oneself; a reverential attitude toward others manifested in the observance of formal rules of conduct such as the way to receive guests; an ability to determine the proper course of conduct, whether this calls for observance of traditional norms or departure from such norms; and a firm commitment to proper conduct so that one is not swayed by adverse circumstances such as poverty or death. Everyone is supposed to have the ability to attain this ideal, and people are urged to exercise constant vigilance over their character so that they can transform themselves to embody this ideal fully. In the political realm, a ruler who embodies the ideal will care about and provide for the people, who will be attracted to him; the moral example he sets will have a transforming effect on the people.

Different Confucian thinkers have different conceptions of the way the ethical ideal may be justified and attained. Mencius (fourth century B.C.) regarded the ideal as a full realization of certain incipient moral inclinations shared by human beings, and emphasized the need to reflect on and fully develop such inclinations. Xunzi (third century B.C.) regarded it as a way of optimizing the satisfaction of pre-social human desires, and emphasized the need to learn the norms governing social distinctions and let them transform and regulate the pursuit of satisfaction of such desires. Different kinds of Confucian thought continued to evolve, yielding such major thinkers as Dong Zhongshu (second century B.C.) and Han Yu (A.D. 768–824). Han Yu regarded Mencius as the true transmitter of Confucius's teachings, and this view became generally accepted, largely through the efforts of Zhu Xi (1130–1200). The Mencian form of Confucian thought continued to be developed in different ways by such major thinkers as Zhu Xi, Wang Yangming (1472–1529), and Dai Zhen (1723–77), who differed concerning the way to attain the Confucian ideal and the metaphysics undergirding it. Despite these divergent developments, Confucius continued to be revered within this tradition of thought as its first and most important thinker, and the Confucian school of thought continued to exert great influence on Chinese life and on the social and political order down to the present century.

See also MENCIUS, WANG YANGMING, ZHU XI.

K.-l.S.

Confucius, also known as Kong Qiu, Kongzi, Kongfuzi (sixth–fifth century B.C.), Chinese thinker usually regarded as founder of the Confucian school of thought. His teachings are recorded in the *Lunyu*, or *Analects*, a collection of sayings by him and by disciples, and of conversations between him and his disciples. His highest ethical ideal is *ren* (humanity, goodness), which includes an affective concern for the well-being of others, desirable attributes (e.g., filial piety) within familial, social, and political institutions, and other desirable attributes such as *yong* (courage, bravery). An important part of the ideal is the general observance of *li* (rites), the traditional norms governing conduct between people related by their different social positions, along with a critical reflection on such norms and a preparedness to adapt them to present circumstances. Human conduct should not be dictated by fixed rules, but should be sensitive to relevant considerations and should accord with *yi* (rightness, duty). Other important concepts include *shu* (consideration, reciprocity), which involves not doing to another what one would not wish done to oneself, and *zhong* (loyalty, commitment), interpreted variously as a commitment to the exercise of *shu*, to the norms of *li*, or to one's duties toward superiors and equals. The ideal of *ren* is within the reach of all, and one should constantly reflect on one's character and correct one's deficiencies. *Ren* has transformative powers that should ideally be the basis of government; a ruler with *ren* will care about and provide for the people, who will be attracted to him, and the moral example he sets will inspire people to reform themselves. **See also** CONFUCIANISM, LI^{2}, REN. K.-l.S.

congruence. See LEWIS, C. I.

conjecture, a propositional speech act, spoken (at least in silent soliloquy) or written, and often distinguished from other speech acts, such as stating and questioning, by its different implicatures, different preambles, and different social consequences. For example, Christian Goldbach (1690–1764) conjectured that every even number exceeding 2 is the sum of two prime numbers. This – the Goldbach conjecture – is still "open": not known to be true or known to be false. Although Goldbach accomplished much, his fame is a social consequence of his conjecture.

Making a statement has the implicature that its speaker believes the proposition stated. A question often implicates that its speaker neither believes nor disbelieves the proposition questioned. The conjecture is a kind of intermediate between a statement and a question. It typically implicates that its speaker believes the proposition conjectured, but it also implicates that its speaker believes the evidence doesn't warrant stating it.

Conjecturing is not equivalent to guessing, since that may be a "stab in the dark," as when one agrees to guess how many candies are in a box. But guessing can be accompanied by belief. Normally, "calling" a coin flip is a guess but not a conjecture. Even if every conjecture is a believed guess, not every believed guess is a conjecture. Sometimes "educated guesses" can be considered conjectures.

Candidates for conjectures are often arrived at by what Peirce called abduction. Conjectures are often justified (to at least some degree) by induction. Some philosophers of science, such as Popper, have used 'conjecture' for framing a hypothesis or for a framed hypothesis. But the act of framing a hypothesis is often evaluated differently than conjecturing: hypotheses are commonly framed to be tested, whereas conjectures often have no such purpose.

See also ABDUCTION, IMPLICATURE, INDUCTION, POPPER, PROPOSITION, SPEECH ACT THEORY.

J.Cor.

conjunction, the logical operation on a pair of propositions that is typically indicated by the coordinating conjunction 'and'. The truth table for conjunction is

P	*Q*	*P*-and-*Q*
T	T	T

Besides 'and', other coordinating conjunctions, including 'but', 'however', 'moreover', and 'although', can indicate logical conjunction, as can the semicolon ';' and the comma ','. **See also** TRUTH TABLE. R.W.B.

conjunction elimination. (1) The argument form '*A* and *B;* therefore, *A* (or *B*)' and arguments of this form. (2) The rule of inference that permits one to infer either conjunct from a conjunction. This is also known as the *rule of simplification* or *∧-elimination*. **See also** CONJUNCTION. G.F.S.

conjunction introduction. (1) The argument form '*A, B;* therefore, *A* and *B*' and arguments of this form. (2) The rule of inference that permits one to infer a conjunction from its two conjuncts. This is also known as the *rule of conjunction introduction*, *∧-introduction*, or *adjunction*. **See also** CONJUNCTION. G.F.S.

conjunctive normal form. See NORMAL FORM.

conjunctivity, the characteristic of a property consisting in its being retained by any conjunction of elements each of which has it; roughly, being closed under the operation of conjunction. Truth is conjunctive in that if *p* is true and *q* is true, then so is the conjunction, *p & q*. It seems that in general conjunctivity may be more the exception than the rule. For instance, the multiplication rule of the probability calculus ensures that being highly probable is not conjunctive. Similarly, that each member of a set of propositions is justified for a given person does not obviously entail that the conjunction of all members of that set is justified for that person. Arguably, each proposition regarding a fair million-ticket lottery stating that ticket *n* will lose is justified even if the proposition that all tickets will lose is clearly not justified. Belief – i.e., the property of being believed by a given person – fails to be conjunctive: one might believe each proposition in a very large set but not believe or even understand their conjunction; or, having considered their conjunction, one might find it to be self-contradictory or otherwise absurd. Finally, if belief is necessary for knowledge, then each member of a set of propositions could be known without their conjunction being known simply because, since belief is not conjunctive, that conjunction may not be believed. Hence knowledge is not conjunctive. **See also** CLOSURE, LOTTERY PARADOX. R.Ke.

connected, said of a relation R where, for any two *distinct* elements x and y of the domain, either xRy or yRx. R is said to be *strongly* connected if, for *any* two elements x and y, either xRy or yRx, even if x and y are identical. Given the domain of positive integers, for instance, the relation $<$ is connected, since for any two distinct numbers a and b, either $a < b$ or $b < a$. However, $<$ is *not* strongly connected, since if $a = b$ we do not have either $a < b$ or $b < a$. The relation $\leq$, on the other hand, is strongly connected, since either $a \leq b$ or $b \leq a$ for any two numbers, including the case where $a = b$. An example of a relation that is not connected is the subset relation $\subseteq$, since it is not true that for any two sets A and B, either $A \subseteq B$ or $B \subseteq A$. **See also** RELATION. V.K.

connectionism, an approach to modeling cognitive systems which utilizes networks of simple processing units that are inspired by the basic structure of the nervous system. Other names for this approach are *neural network modeling* and *parallel distributed processing*. Connectionism was pioneered in the period 1940–65 by researchers such as Frank Rosenblatt and Oliver Selfridge. Interest in using such networks diminished during the 1970s because of limitations encountered by existing networks and the growing attractiveness of the computer model of the mind (according to which the mind stores symbols in memory and registers and performs computations upon them). Connectionist models enjoyed a renaissance in the 1980s, partly as the result of the discovery of means of overcoming earlier limitations (e.g., development of the back-propagation learning algorithm by David Rumelhart, Geoffrey Hinton, and Ronald Williams, and of the Boltzmann-machine learning algorithm by David Ackley, Geoffrey Hinton, and Terrence Sejnowski) and partly as limitations encountered with the computer model rekindled interest in alternatives. Researchers employing connectionist-type nets are found in a variety of disciplines, including psychology, artificial intelligence, neuroscience, and physics. There are often major differences in the endeavors of these researchers: psychologists and artificial intelligence researchers are interested in using these nets to model cognitive behavior, whereas neuroscientists often use them to model processing in particular neural systems.

A connectionist system consists of a set of processing units that can take on activation values. These units are connected so that particular units can excite or inhibit others. The activation of any particular unit will be determined by one or more of the following: inputs from outside the system, the excitations or inhibitions supplied by other units, and the previous activation of the unit. There are a variety of architectures invoked in connectionist systems. In *feed forward nets* units are clustered into layers and connections pass activations in a unidirectional manner from a layer of input units to a layer of output units, possibly passing through one or more layers of hidden units along the way. In these systems processing requires one pass of processing through the network. *Interactive nets* exhibit no directionality of processing: a given unit may excite or inhibit another unit, and it, or another unit influenced by it, might excite or inhibit the first unit. A number of processing cycles will ensue after an input has been given to some or all of the units until eventually the network settles into one state, or cycles through a small set of such states.

One of the most attractive features of connectionist networks is their ability to learn. This is accomplished by adjusting the weights connecting the various units of the system, thereby altering the manner in which the network responds to inputs. To illustrate the basic process of connectionist learning, consider a feed forward network with just two layers of units and one layer of connections. One learning procedure (commonly referred to as the *delta rule*) first requires the network to respond, using current weights, to an input. The activations on the units of the second layer are then compared to a set of target activations, and detected differences are used to adjust the weights coming from active input units. Such a procedure gradually reduces the difference between the actual response and the target response.

In order to construe such networks as cognitive models it is necessary to interpret the input and output units. *Localist* interpretations treat individual input and output units as representing concepts such as those found in natural language. *Distributed* interpretations correlate only patterns of activation of a number of units with ordinary language concepts. Sometimes (but not always) distributed models will interpret individual units as corresponding to micro features. In one interesting variation on distributed representation, known as *coarse coding*, each symbol will be assigned to a different subset of the units of the system, and the symbol will be viewed as active only if a predefined number of the assigned units are active.

A number of features of connectionist nets make them particularly attractive for modeling cognitive phenomena in addition to their ability to learn from experience. They are extremely efficient at pattern-recognition tasks and often generalize very well from training inputs to similar test inputs. They can often recover complete patterns from partial inputs, making them good models for content-addressable memory. Interactive networks are particularly useful in modeling cognitive tasks in which multiple constraints must be satisfied simultaneously, or in which the goal is to satisfy competing constraints as well as possible. In a natural manner they can override some constraints on a problem when it is not possible to satisfy all, thus treating the constraints as *soft*. While the cognitive connectionist models are not intended to model actual neural processing, they suggest how cognitive processes can be realized in neural hardware. They also exhibit a feature demonstrated by the brain but difficult to achieve in symbolic systems: their performance degrades gracefully as units or connections are disabled or the capacity of the network is exceeded, rather than crashing.

Serious challenges have been raised to the usefulness of connectionism as a tool for modeling cognition. Many of these challenges have come from theorists who have focused on the complexities of language, especially the systematicity exhibited in language. Jerry Fodor and Zenon Pylyshyn, e.g., have emphasized the manner in which the meaning of complex sentences is built up compositionally from the meaning of components, and argue both that compositionality applies to thought generally and that it requires a symbolic system. Therefore, they maintain, while cognitive systems might be implemented in connectionist nets, these nets do not characterize the architecture of the cognitive system itself, which must have capacities for symbol storage and manipulation. Connectionists have developed a variety of responses to these objections, including emphasizing the importance of cognitive functions such as pattern recognition, which have not been as successfully modeled by symbolic systems; challenging the need for symbol processing in accounting for linguistic behavior; and designing more complex connectionist architectures, such as recurrent networks, capable of responding to or producing systematic structures.

consequentialism, the doctrine that the moral rightness of an act is determined solely by the goodness of the act's consequences. Prominent consequentialists include J. S. Mill, Moore, and Sidgwick. Maximizing versions of consequentialism – the most common sort – hold that an act is morally right if and only if it produces the *best* consequences of those acts available to the agent. Satisficing consequentialism holds that an act is morally right if and only if it produces *enough* good consequences on balance. Consequentialist theories are often contrasted with deontological ones, such as Kant's, which hold that the rightness of an act is determined at least in part by something other than the goodness of the act's consequences.

A few versions of consequentialism are agent-relative: that is, they give each agent different aims, so that different agents' aims may conflict. For instance, egoistic consequentialism holds that the moral rightness of an act for an agent depends solely on the goodness of its consequences for the agent. However, the vast majority of consequentialist theories have been agent-neutral (and consequentialism is often defined in a more restrictive way so that agent-relative versions do not count as consequentialist). A doctrine is agent-neutral when it gives to each agent the same ultimate aims, so that different agents' aims cannot conflict. For instance, utilitarianism holds that an act is morally right if and only if it produces more happiness for the sentient beings it affects than any other act available to the agent. This gives each agent the same ultimate aim, and so is agent-neutral.

Consequentialist theories differ over what features of acts they hold to determine their goodness. Utilitarian versions hold that the only consequences of an act relevant to its goodness are its effects on the happiness of sentient beings. But some consequentialists hold that the promotion of other things matters too – achievement, autonomy, knowledge, or fairness, for instance. Thus utilitarianism, as a maximizing, agent-neutral, happiness-based view, is only one of a broad range of consequentialist theories.

consequentia mirabilis, the logical principle that if a statement follows from its own negation it must be true. *Strict consequentia mirabilis* is the principle that if a statement follows logically from its own negation it is logically true. The principle is often connected with the paradoxes of strict implication, according to which any statement follows from a contradiction. Since the negation of a tautology is a contradiction, every tautology follows from its own negation. However, if every expression of the form 'if *p* then *q*' implies 'not-*p* or *q*' (they need not be equivalent), then from 'if not-*p* then *p*' we can derive 'not-not-*p* or *p*' and (by the principles of double negation and repetition) derive *p*. Since all of these rules are unexceptionable the principle of *consequentia mirabilis* is also unexceptionable. It is, however, somewhat counterintuitive, hence the name ('the astonishing implication'), which goes back to its medieval discoverers (or rediscoverers). **See also** IMPLICATION. R.P.

consistency, in traditional Aristotelian logic, a semantic notion: two or more statements are called consistent if they are simultaneously true under some interpretation (cf., e.g., W. S. Jevons, *Elementary Lessons in Logic*, 1870). In modern logic there is a syntactic definition that also fits complex (e.g., mathematical) theories developed since Frege's *Begriffsschrift* (1879): a set of statements is called consistent with respect to a certain logical calculus if no formula '*P* & –*P*' is derivable from those statements by the rules of the calculus; i.e., the theory is free from contradictions. If these definitions are equivalent for a logic, we have a significant fact, as the equivalence amounts to the completeness of its system of rules. The first such completeness theorem was obtained for sentential or propositional logic by Paul Bernays in 1918 (in his *Habilitationsschrift*, which was partially published as *Axiomatische Untersuchung des Aussagen-Kalküls der "Principia Mathematica,"* 1926) and, independently, by Emil Post (in *Introduction to a General Theory of Elementary Propositions*, 1921); the completeness of predicate logic was proved by Gödel (in *Die Vollständigkeit der Axiome des logischen Funktionenkalküls*, 1930). The crucial step in such proofs shows that syntactic consistency implies semantic consistency.

Cantor applied the notion of consistency to sets. In a well-known letter to Dedekind (1899) he distinguished between an inconsistent and a consistent multiplicity; the former is such "that the assumption that all of its elements 'are together' leads to a contradiction," whereas the elements of the latter "can be thought of without contradiction as 'being together'." Cantor had conveyed these distinctions and their motivation by letter to Hilbert in 1897 (see W. Purkert and H. J. Ilgauds, *Georg Cantor*, 1987). Hilbert pointed out explicitly in 1904 that Cantor had not given a rigorous criterion for distinguishing between consistent and inconsistent multiplicities. Already in his *Über den Zahlbegriff* (1899) Hilbert had suggested a remedy by giving consistency proofs for suitable axiomatic systems; e.g., to give the proof of the "existence of the totality of real numbers or – in the terminology of G. Cantor – the proof of the fact that the system of real numbers is a consistent (complete) set" by establishing the consistency of an axiomatic characterization of the reals – in modern terminology, of the theory of complete, ordered fields. And he claimed, somewhat indeterminately, that this could be done "by a suitable modification of familiar methods."

After 1904, Hilbert pursued a new way of giving consistency proofs. This novel way of proceeding, still aiming for the same goal, was to make use of the formalization of the theory at hand. However, in the formulation of Hilbert's program during the 1920s the point of consistency proofs was no longer to guarantee the existence of suitable sets, but rather to establish the instrumental usefulness of strong mathematical theories **T**, like axiomatic set theory, relative to finitist mathematics. That focus rested on the observation that the statement formulating the syntactic consistency of **T** is equivalent to the reflection principle $\mathrm{Pr}(a, `s') \to s$; here Pr is the finitist proof predicate for **T**, *s* is a finitistically meaningful statement, and '*s*' its translation into the language of **T**. If one could establish finitistically the consistency of **T**, one could be sure – on finitist grounds – that **T** is a reliable instrument for the proof of finitist statements.

There are many examples of significant relative consistency proofs: (i) non-Euclidean geometry relative to Euclidean, Euclidean geometry relative to analysis; (ii) set theory with the axiom of choice relative to set theory (without the axiom of choice), set theory with the negation of the axiom of choice relative to set theory; (iii) classical arithmetic relative to intuitionistic arithmetic, subsystems of classical analysis relative to intuitionistic theories of constructive ordinals. The mathematical significance of relative consistency proofs is often brought out by sharpening them to establish conservative extension results; the latter may then ensure, e.g., that the theories have the same class of provably total functions. The initial motivation for such arguments is, however, frequently philosophical: one wants to guarantee the coherence of the original theory on an epistemologically distinguished basis.

Constant, Benjamin, Henri-Benjamin Constant de Rebecque (1767–1830), Swiss-born defender of liberalism and passionate analyst of French and European politics. He welcomed the French Revolution but not the Reign of Terror, the violence of which he avoided by accepting a lowly diplomatic post in Braunschweig (1787–94). In 1795 he returned to Paris with Madame de Staël and intervened in parliamentary debates. His pamphlets opposed both extremes, the Jacobin and the Bonapartist. Impressed by Rousseau's *Social Contract*, he came to fear that like Napoleon's dictatorship, the "general will" could threaten civil rights. He had first welcomed Napoleon, but turned against his autocracy. He favored parliamentary democracy, separation of church and state, and a bill of rights. The high point of his political career came with membership in the Tribunat (1800–1802), a consultative chamber appointed by the Senate.

His centrist position is evident in the *Principes de politique* (1806–10). Had not republican terror been as destructive as the Empire? In Chapters 16 and 17, Constant opposes the liberty of the ancients and that of the moderns. He assumes that the Greek world was given to war, and therefore strengthened "political liberty" that favors the state over the individual – the *liberty of the ancients*. Fundamentally optimistic, he believed that war was a thing of the past, and that the modern world needed to protect "civil liberty," i.e. the liberty of the individual – the *liberty of the moderns*. The great merit of Constant's comparison is the analysis of historical forces, the theory that governments must support current needs and do not depend on deterministic factors such as the size of the state, its form of government, geography, climate, and race. Here he contradicts Montesquieu. The opposition between ancient and modern liberty expresses a radical liberalism that did not seem to fit French politics. However, it was the beginning of the liberal tradition, contrasting political liberty in the service of the state with the civil liberty of the citizen (cf. Mill's *On Liberty*, 1859; Berlin's *Two Concepts of Liberty*, 1958). *Principes* remained in manuscript until 1861; the scholarly editions of Étienne Hofmann (1980) are far more recent. Hofmann calls *Principes* the essential text between Montesquieu and Tocqueville. It was translated into English as *Constant, Political Writings* (ed. Biancamaria Fontana, 1988, 1997).

Forced into retirement by Napoleon, Constant wrote his literary masterpieces, *Adolphe* and the diaries. He completed the *Principes*, then turned to *De la religion* (6 vols.), which he considered his supreme achievement.

constitution, in its broad use, a relation that (e.g.) a statue-shaped lump of clay bears to the clay statue that it makes up: the lump *constitutes* the statue. This broad use leaves open the question, what *is* the relation between the statue and the lump? Some say that the lump is identical to the statue, given that they are made of the same matter and have the same spatial location. (More generally, some hold that constitution is identity, or at least entails it.) Others say that the lump is not identical to the statue (hence that constitution does not even entail identity), given that the lump and the statue seem to differ – e.g., historically (the lump existed before it was statue-shaped and hence before the statue existed), modally (even in cases in which they are spatially co-located throughout their careers, the lump but not the statue *could* survive being squashed flat), and aesthetically (the statue, but not the lump, is well made).

There is also a narrow use of 'constitution' on which constitution is asymmetric and hence irreflexive. On this use, constitution entails *non-identity*: e.g., the proposition that the lump constitutes the statue entails that the lump is not identical to the statue. There is no universally accepted definition of '*x* constitutes *y*', on the narrow use, but it is often assumed that *x* constitutes *y* if and only if (1) *x mereologically coincides* with *y*, i.e. *x* and *y* overlap (share parts with) exactly the same things, and (2) with regard to the range of possible situations in which *x* and/or *y* could exist, *x* is "more closely tied" to its actual parts or its actual matter than is *y*: e.g., *y* could exist while having only, say, half of its actual parts, but *x* could not. Thus, given that the lump and the statue stand in the (symmetric) relation of mereological-coincidence-without-identity, the lump constitutes the statue (and not the other way around) because the lump's modal connection to its actual parts is tighter than is the statue's.

Constitution should be distinguished from *composition*, where '*x* is composed of the *y*s' is defined as 'Each of the *y*s is a part of *x*, and each part of *x* overlaps at least one of the *y*s'. So understood, composition holds between an individual thing and *some things* ('a plurality'), whereas constitution holds between an individual and an individual. If constitution entails mereological-coincidence-without-identity, then (assuming that parthood is reflexive and transitive) the claim that one thing constitutes another is incompatible with the *uniqueness of composition*, the principle that if *x* is composed of the *y*s and *z* is composed of the *y*s, then $x = z$.

The paradigm cases of constitution involve *substances* and in particular *material objects* (lumps and statues or, more controversially, bodies and persons); 'material constitution' sometimes denotes a constitution relation that holds only between material objects. Some philosophers have claimed that constitution itself is a more general relation that can also hold between entities in other ontological categories, e.g. events, so that a particular neural firing, say, constitutes a particular conscious experience, or properties so that *having C-fibers that are firing* constitutes *being in pain*.

constructive dilemma. See DILEMMA.

constructive empiricism, the view that science aims to produce theories that are true with respect to the observable aspects of the world (empirically adequate) and that the epistemic commitment accompanying unqualified acceptance of a theory need involve only the belief that it is empirically adequate. Constructive empiricism was originally defended by van Fraassen in *The Scientific Image* (1980) as an alternative to prevailing forms of scientific realism after the linguistic theses of the logical positivists were abandoned. Like realism (but unlike forms of instrumentalism, conventionalism, and positivism which regard theoretical vocabulary as merely heuristic or dispensable), constructive empiricism construes the language of science literally, as making claims about the external world that are either true or false. The view rests on a distinction between observable and unobservable entities, which van Fraassen understands as an empirical question about the limitations of unaided human perception. Thus the moons of Jupiter would, in principle, be observable to us were we close enough, while quarks and electrons are not. Though intended as an interpretation of scientific activity rather than a view about what we should believe, constructive empiricism avoids metaphysics by accounting for the practice and success of science in ways consistent with agnosticism about the reality of unobservables. Constructive empiricism is elaborated with respect to a host of issues, including a critique of inference to the best explanation, analyses of the pragmatics of explanation and probabilistic judgments, and, more recently, in connection with van Fraassen's general perspective on rationality and voluntarist epistemology. **See also** ANTI-REALISM, EMPIRICAL ADEQUACY, EMPIRICISM, LOGICAL POSITIVISM, PHILOSOPHY OF SCIENCE, SCIENTIFIC REALISM, VAN FRAASSEN, VIENNA CIRCLE. content, what is expressed or meant by an indicative sentence or an utterance of an indicative sentence, what is believed or entertained when one believes or thinks a thought or proposition, or what is represented in perceptual experience. Items with content include: words and sentences (linguistic content); utterances of words and sentences and other communicative acts (utterance content); perceptual states (perceptual content); and thoughts and other propositional attitudes (thought content). Content is closely related to meaning, representation, information, and intentionality.

Correctness-conditions. Contents are correctness-conditions: the conditions, or contributions to the conditions under which a sentence, utterance, perception, or thought is correct. Content is like information contained in a newspaper. If what the newspaper says is true, then it contains correct information; if false, then misinformation.

Truth-conditions and accuracy-conditions are two kinds of correctness-condition. Indicative sentences like 'Reno is west of Los Angeles' have truth-conditions. The sentence is true if and only if Reno is west of Los Angeles. Beliefs also have truth-conditions. If I believe Reno is west of Los Angeles, my belief is true if and only if Reno is west of Los Angeles. Maps differ. Unlike sentences and beliefs, maps are accurate or inaccurate as opposed to true or false. A map is correct to the extent that it is accurate. Some philosophers argue that perceptual states are more like maps and have accuracy-conditions instead of truth-conditions as contents.

Ways of having contents. Contents differ from ways of having contents. Consider thoughts. You might *hope* that Bob is early for the party. Someone else might *fear* that Bob is early. A third person might *believe* that Bob is early. A fourth might simply *consider* the possibility that Bob is early. These are four ways of having the same content. The different *ways* of having thoughts are called *attitudes*.

When it comes to perception, the different ways are *modes*. You visually see a particular ball as round and also pick it up and feel its round shape. Your visual and tactile perceptions have the same content: *the roundness of that object*. But *seeing* the ball's roundness and *feeling* its roundness are different perceptual modes or modalities. Perceptual content is intermodal when different perceptual modes can have the same content. Some perceptual contents are intermodal and some are not. You can only represent colors visually, for example.

When it comes to utterances, content differs from *force* (usually called *illocutionary force*). You can utter 'The door is closed' to *assert* that it is closed or, with a rising intonation, to *ask* whether it is closed. Your utterances have the same content but differ in force: assertive and interrogative.

Three theories of contents. What are correctness-conditions? Some philosophers take them as unexplained primitives. Others try to explain them. Among those who do, three theories are prominent: Russellian, Fregean, and possible-worlds. On the possible-worlds theory, correctness-conditions are sets of possible worlds.

An item is correct if and only if the actual world is a member of the set of possible worlds that is its content. The content of 'Aristotle is a philosopher' is the set of all possible worlds where Aristotle is a philosopher. If the actual world is in that set, 'Aristotle is a philosopher' is correct.

The main objection involves necessary truths and falsehoods. Take '2 + 2 = 4' and '187 × 95 = 17,765'. Both are true in all possible worlds, and so they would have the same content. But one can believe one without believing the other, assert one without asserting the other, and so on. Apparently, possible worlds are too coarse-grained to capture contents.

On the Russellian theory, contents are structured propositions: abstract objects that contain individual objects (concrete or abstract), properties, quantifiers, and logical relations. *Singular* Russellian propositions contain individual objects and properties or relations. *Quasi*-singular Russellian propositions contain individuals, properties or relations, quantifiers, and logical relations. *General* Russellian propositions contain no individuals, and contain only properties, relations, quantifiers, and logical relations. The content of 'Aristotle is a philosopher' might then be a singular proposition with Aristotle himself and the property of being a philosopher as constituents. The content of a perceptual state *that round red object* might then be a singular proposition with the object itself and the properties of being round and red as constituents. And the content of '2 + 2 = 4' might be a singular proposition with the numbers 2 and 4, and the logical relations of addition and numerical equality, as constituents. On this view '187 × 95 = 17,765' would then have a very different content from '2 + 2 = 4'. And so on this view contents are more fine-grained than they are on the possible-worlds view.

But perhaps they are not yet fine-grained enough. For consider 'Mark Twain is clever' and 'Samuel Clemens is clever'. Since 'Mark Twain' and 'Samuel Clemens' co-refer, the contents would be the same on a Russellian theory that took their contents to be singular propositions. (Russell himself took their contents to be quasi-singular, and so different propositions.) But I might believe that Mark Twain is clever without believing that Samuel Clemens is clever.

Fregean theories are more traditional. They postulate *senses* or *modes of presentation* as contents. "Senses" are ways of thinking about, and ways of perceptually representing, individuals, properties, and relations that determine the individuals, properties, and relations that the thinker is thinking about. 'Sense' is Frege's term for what others might call *concepts*, *notions*, *percepts*, or *ideas*. The content of 'Mark Twain is clever' would then involve a *Mark-Twain* sense and a *being-clever* sense. The individual's thought would be correct if and only if the individual determined by *Mark-Twain* has the property determined by *being-clever*. Since a thinker's *Mark-Twain* sense need not be the same as the thinker's *Samuel-Clemens* sense, the thinker can believe that Mark Twain is clever without believing that Samuel Clemens is clever. Although Fregean theories are thus better suited to capture fineness of grain, possible-worlds and Russellian theories are currently very popular, in part because they hope to explain content without postulating senses or concepts. Which theory is best is a matter of ongoing controversy.

Debates about content are sometimes put in terms of "wide" (or "external") content versus "narrow" (or "internal") content. On a Russellian theory, if you think the content of a sentence or thought is singular, then you may say it has a "wide" or "external" content if it involves an individual object "outside" of the thinker's mind. But if you think the contents are general Russellian propositions, then you may say instead that they are "narrow" or "internal." Others will call Fregean theories "narrow" or "internal," for they better characterize the thinkers' "internal" psychology or point of view on external objects.

These theories are not mutually exclusive. Many have advanced possible-worlds or Russellian theories for linguistic content (such theories dominate in philosophy of language), while others find Fregean theories more attractive for perceptual and thought content. Some even defend mixed theories for a kind of content. For example, "neo-Fregean" theories see perceptual content as involving a Russellian singular proposition and a Fregean sense.

The theory of content. How do states of the brain, sentences in a language, and utterances of words come to have, or be individuated by, contents? Most answers focus first on mental content. The main debate then concerns where to look for an answer. One side says to look only "inside" the brain to see why brain states have, or are associated with, contents. The other side says to look "outside" as well. On the first, current non-intentional, non-representational features of the individual's brain and nervous system fix mental contents. Mental contents then supervene "narrowly" on features "internal" to the individual. On the second, mental contents are also fixed by patterns of interaction between the individual and her broader physical and social environment, including her learning and evolutionary history. Mental contents then supervene "widely" on features "external" to the individual.

Consider a dime. Its shape is fixed by the way its particles hold together. Its shape supervenes "narrowly." Any duplicate would have the same shape. But its value depends in part on where it was manufactured – in a U.S. mint – and the way it is used as a means of exchange for goods and services. Counterfeit dimes, or dimes without the system of exchange, would not have the same monetary value. So its value supervenes "widely." Advocates of the first theory see mental content like shape. Advocates of the second see mental content like value.

A main argument for "externalism" involves Twin Earth. Tyler Burge – inspired by Putnam – imagined molecule-for-molecule twins in different physical and social environments where, intuitively, they had different thoughts. One might believe that *water is wet* while the other believes that *twater is wet*, where twater is a look-alike substance to water but has a very different chemical composition. If they believe different things, then they think different contents, even though they are "narrow" duplicates.

Another argument is explanatory. How is it possible to think about and perceptually represent individuals, objects, properties, and relations? Answer: by standing in complex patterns of relations with the individuals and objects, and instances of those properties and relations. Since the complex patterns go beyond our current "internal" brain states, content supervenes "widely."

A main objection involves causal explanations. We appeal to the contents of individuals' thoughts and desires to explain their behavior. Susan went to the bakery, for example, because she wanted to buy bread and believed the shop was open. But causation is "local" and depends on current "internal" properties. Then, if content causally explains behavior, content should supervene "narrowly."

Another involves *Swampman*. Imagine a molecule-for-molecule duplicate of you mysteriously created when a bolt of lightning hits a log in a swamp, with no causal or explanatory connection to you or any living creature. Could "Swampman" think about shapes and colors, shopping malls, and carburetors? Many say yes. But then content must supervene "narrowly."

It is important not to conflate this debate with the debate about what contents are. Suppose contents are senses. We can still ask how or why an individual can think or access this or that sense. Is it because of features solely "internal" to the individual, or "external" as well? Suppose contents are sets of possible worlds. How can an individual think a thought with this or that set of possible worlds as its content? It is because of features solely "internal" to the individual, or "external" as well? What contents are, and what they supervene upon, are different, though related questions.

contextual definition. See DEFINITION.

contextualism, the view that the epistemic status of a propositional attitude – its being praiseworthy or valuable, as when a belief is *justified* or a case of *knowledge* – partly depends on contextual factors, such as the salience of error possibilities. The core of the view is outlined in Wittgenstein, J. L. Austin, and Norman Malcolm, though 'contextualism' is a recent coinage.

Contemporary epistemology exhibits two main varieties. *Inferential contextualism* has been developed by David Annis and Michael Williams as an alternative to the traditional responses to the skeptical argument known as "Agrippa's trilemma," foundationalism, and coherentism. The view is usually regarded as a form of foundationalism: some beliefs are contextually foundational; their status as knowledge may be properly presupposed and they are thus available as a basis for inferential knowledge. But contextualism differs from both "classical" and "moderate" (or "modest") foundationalism in holding both that, apart from legitimate challenges to their status as knowledge, contextually foundational beliefs require no justification and that all justification is inferential.

Because inferential contextualists reject the felt need to account for foundational epistemic status as foundationalists normally do, the *structural* advantages of foundationalism over coherentism – notably, avoiding circularity – accrue to contextualist foundationalism. However, contextualists must then explain how foundational status occasionally seems to come "free." Critics complain, on behalf of the skeptic, that the contextualist emphasis on the dynamics of dialectical challenges yields counterintuitive consequences. The most obvious of these is that (where *p* is true) believing *p* would, for even someone credulous and generally uninformed, seem to be knowledge in an unthreatening context, but would not qualify as knowledge in a context where experts deny *p*, even where the evidence on which *p* is believed remains the same. This apparently contravenes the intuitive idea that whether a true belief counts as knowledge is a matter of its relation to grounding evidence. The very same critics, however, must concede that *ascriptions* of both knowledge and justification do vary as contextualists say. The motivation for an account of our inconsistency in the use of epistemic terms is, therefore, important for epistemology.

The other major form of contemporary contextualism descends from Gail Stine's critique of Dretske's theory of *relevant alternatives*. Dretske held (against skeptics about ordinary knowledge claims) that the epistemic status of a belief is not closed under known entailment; you may, for instance, know that the animals you see at the zoo are zebras, know that their being zebras entails that they are not perfectly disguised mules, infer that they are not perfectly disguised mules from your belief that they are zebras, and yet fail to know that the animals are not perfectly disguised mules. The attack on epistemic closure principles as a way around skepticism has been widely regarded as unfortunate. Stine countered that Dretske failed to see that the "standards" (or "criteria") for knowledge in the case of a belief that one sees zebras on the basis of the evidence provided by casual observation are dramatically different from the much higher standards that one would have to meet to refute a skeptical hypothesis, say that the animals are really zebra-looking mules. Her point about varying standards for knowledge spawned the form of contextualism found in the works of Stewart Cohen, Keith DeRose, and David Lewis. Lewis suggested that the context-sensitivity of knowledge attributions is determined by the salience of skeptical hypotheses in conversational contexts. This is supposed to account for the fact that someone properly described as knowing that *p* in a "low-standards" context, on the basis of a given body of evidence *E*, may also properly be described as not knowing that *p* on *E* in a "high-standards" context. This fundamental contextualist claim is developed by both Cohen and DeRose into *semantic contextualism*. This view is often called *semantic* because it seeks to explain the diverging, but seemingly correct attributions of knowledge or justification, while the relevant body of evidence is held fixed, as a function of varying truth-conditions of knowledge ascriptions. These varying truth-conditions are in turn explained as due to semantic features of 'knows that' which make such locutions akin to indexicals ('here', 'now', etc.) and gradable adjectives ('tall', 'flat', etc.).

Contextualist claims are among the most hotly contested in epistemology. In terminology due partly to Peter Unger and Jonathan Kvanvig, contextualists are opposed by "invariantists," some of whom hold "pragmatic encroachment" views.

contiguity. See ASSOCIATIONISM.

continence. See AKRASIA.

Continental philosophy, the gradually changing spectrum of philosophical views that in the twentieth century developed in Continental Europe and that are notably different from the various forms of analytic philosophy that, during the same period, flourished in the Anglo-American world. Immediately after World War II the expression was more or less synonymous with 'phenomenology'. The latter term, already used earlier in German idealism, received a completely new meaning in the work of Husserl. Later on the term was also applied, often with substantial changes in meaning, to the thought of a great number of other Continental philosophers such as Scheler, Alexander Pfander, Hedwig Conrad-Martius, Nicolai Hartmann, and most philosophers mentioned below. For Husserl the aim of philosophy is to prepare humankind for a genuinely philosophical form of life, in and through which each human being gives him- or herself a rule through reason. Since the Renaissance, many philosophers have tried in vain to materialize this aim. In Husserl's view, the reason was that philosophers failed to use the proper philosophical method. Husserl's phenomenology was meant to provide philosophy with the method needed.

Among those deeply influenced by Husserl's ideas the so-called existentialists must be mentioned first. If 'existentialism' is construed strictly, it refers mainly to the philosophy of Sartre and Beauvoir. In a very broad sense it refers to the ideas of an entire group of thinkers influenced methodologically by Husserl and in content by Marcel, Heidegger, Sartre, or Merleau-Ponty. In this case one often speaks of *existential phenomenology*.

When Heidegger's philosophy became better known in the Anglo-American world, 'Continental philosophy' again received a new meaning. From Heidegger's first publication, *Being and Time* (1927), it was clear that his conception of phenomenology differs from that of Husserl in several important respects. That is why he qualified the term and spoke of *hermeneutic phenomenology* and clarified the expression by examining the "original" meaning of the Greek words from which the term was formed. In his view phenomenology must try "to let that which shows itself be seen from itself in the very way in which it shows itself from itself." Heidegger applied the method first to the mode of being of man with the aim of approaching the question concerning the meaning of being itself through this phenomenological interpretation. Of those who took their point of departure from Heidegger, but also tried to go beyond him, Gadamer and Ricoeur must be mentioned.

The structuralist movement in France added another connotation to 'Continental philosophy'. The term 'structuralism' above all refers to an activity, a way of knowing, speaking, and acting that extends over a number of distinguished domains of human activity: linguistics, aesthetics, anthropology, psychology, psychoanalysis, mathematics, philosophy of science, and philosophy itself. Structuralism, which became a fashion in Paris and later in Western Europe generally, reached its high point on the Continent between 1950 and 1970. It was inspired by ideas first formulated by Russian formalism (1916–26) and Czech structuralism (1926–40), but also by ideas derived from the works of Marx and Freud. In France Foucault, Barthes, Althusser, and Derrida were the leading figures. Structuralism is not a new philosophical movement; it must be characterized by structuralist activity, which is meant to evoke ever new objects. This can be done in a constructive and a reconstructive manner, but these two ways of evoking objects can never be separated. One finds the constructive aspect primarily in structuralist aesthetics and linguistics, whereas the reconstructive aspect is more apparent in philosophical reflections upon the structuralist activity. Influenced by Nietzschean ideas, structuralism later developed in a number of directions, including post-structuralism; in this context the works of Gilles Deleuze, Lyotard, Irigaray, and Kristeva must be mentioned.

After 1970 'Continental philosophy' received yet another connotation: *deconstruction*. At first deconstruction presented itself as a reaction against philosophical hermeneutics, even though both deconstruction and hermeneutics claim their origin in Heidegger's reinterpretation of Husserl's phenomenology. The leading philosopher of the movement is Derrida, who at first tried to think along phenomenological and structuralist lines. Derrida formulated his "final" view in a linguistic form that is both complex and suggestive. It is not easy to state in a few sentences what deconstruction is. Generally speaking one can say that what is being deconstructed is texts; they are deconstructed to show that there are conflicting conceptions of meaning and implication in every text so that it is never possible definitively to show what a text really means. Derrida's own deconstructive work is concerned mainly with philosophical texts, whereas others apply the "method" predominantly to literary texts. What according to Derrida distinguished philosophy is its reluctance to face the fact that it, too, is a product of linguistic and rhetorical figures. Deconstruction is here that process of close reading that focuses on those elements where philosophers in their work try to erase all knowledge of its own linguistic and rhetorical dimensions. It has been said that if construction typifies modern thinking, then deconstruction is the mode of thinking that radically tries to overcome modernity. Yet this view is simplistic, since one also deconstructs Plato and many other thinkers and philosophers of the premodern age.

People concerned with social and political philosophy who have sought affiliation with Continental philosophy often appeal to the so-called critical theory of the Frankfurt School in general, and to Habermas's theory of communicative action in particular. Habermas's view, like the position of the Frankfurt School in general, is philosophically eclectic. It tries to bring into harmony ideas derived from Kant, German idealism, and Marx, as well as ideas from the sociology of knowledge and the social sciences. Habermas believes that his theory makes it possible to develop a communication community without alienation that is guided by reason in such a way that the community can stand freely in regard to the objectively given reality. Critics have pointed out that in order to make this theory work Habermas must substantiate a number of assumptions that until now he has not been able to justify.

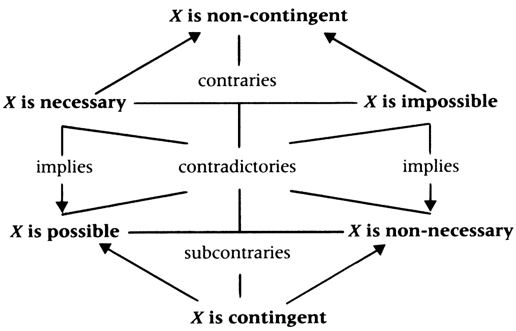
Continental rationalism. See RATIONALISM.

contingent, neither impossible nor necessary; i.e., both possible and non-necessary. The modal property of being contingent is attributable to a proposition, state of affairs, event, or – more debatably – an object. Muddles about the relationship between this and other modal properties have abounded ever since Aristotle, who initially conflated contingency with possibility but later realized that something that is possible may also be necessary, whereas something that is contingent cannot be necessary. Even today many philosophers are not clear about the "opposition" between contingency and necessity, mistakenly supposing them to be contradictory notions (probably because within the domain of *true* propositions the contingent and the necessary are indeed both exclusive and exhaustive of one another). But the contradictory of 'necessary' is 'non-necessary'; that of 'contingent' is 'non-contingent', as the following extended modal square of opposition shows:



These logico-syntactical relationships are preserved through various semantical interpretations, such as those involving: (a) the logical modalities (proposition *P* is logically contingent just when *P* is neither a logical truth nor a logical falsehood); (b) the causal or physical modalities (state of affairs or event *E* is physically contingent just when *E* is neither physically necessary nor physically impossible); and (c) the deontic modalities (act *A* is morally indeterminate just when *A* is neither morally obligatory nor morally forbidden).

In none of these cases does 'contingent' mean 'dependent', as in the phrase 'is contingent upon'. Yet just such a notion of contingency seems to feature prominently in certain formulations of the cosmological argument, all created objects being said to be contingent beings and God alone to be a necessary or non-contingent being. Conceptual clarity is not furthered by assimilating this sense of 'contingent' to the others.

continuum hypothesis. See CANTOR, CONTINUUM PROBLEM.

continuum problem, an open question that arose in Cantor's theory of infinite cardinal numbers. By definition, two sets have the same *cardinal number* if there is a one-to-one correspondence between them. For example, the function that sends 0 to 0, 1 to 2, 2 to 4, etc., shows that the set of even natural numbers has the same cardinal number as the set of all natural numbers, namely $\aleph_0$. That $\aleph_0$ is not the only infinite cardinal follows from *Cantor's theorem:* the *power set* of any set (i.e., the set of all its subsets) has a greater cardinality than the set itself. So, e.g., the power set of the natural numbers, i.e. the set of all sets of natural numbers, has a cardinal number greater than $\aleph_0$. The first infinite number greater than $\aleph_0$ is $\aleph_1$; the next after that is $\aleph_{2'}$; and so on.

When arithmetical operations are extended into the infinite, the cardinal number of the power set of the natural numbers turns out to be $2^{\aleph_0}$. By Cantor's theorem, $2^{\aleph_0}$ must be greater than $\aleph_0$; the conjecture that it is equal to $\aleph_1$ is *Cantor's continuum hypothesis* (in symbols, CH or $2^{\aleph_0} = \aleph_1$). Since $2^{\aleph_0}$ is also the cardinality of the set of points on a continuous line, CH can also be stated in this form: any infinite set of points on a line can be brought into one-to-one correspondence either with the set of natural numbers or with the set of all points on the line.

Cantor and others attempted to prove CH, without success. It later became clear, due to the work of Gödel and Cohen, that their failure was inevitable: the continuum hypothesis can neither be proved nor disproved from the axioms of set theory (ZFC). The question of its truth or falsehood – the continuum problem – remains open.

P.Mad.

contractarianism, a family of moral and political theories that make use of the idea of a social contract. Traditionally philosophers (such as Hobbes and Locke) used the social contract idea to justify certain conceptions of the state. In the twentieth century philosophers such as Rawls have used the social contract notion – sometimes under the term 'contractualism' – to define and defend moral conceptions (both conceptions of political justice and individual morality), often (if not always) doing so in addition to developing social contract theories of the state. The term 'contractarian' most often applies to this second type of theory.

There are two kinds of moral argument that the contract image has spawned, the first rooted in Hobbes and the second rooted in Kant. Hobbesians start by insisting that what is valuable is what a person desires or prefers, not what he ought to desire or prefer (for no such prescriptively powerful object exists); and rational action is action that achieves or maximizes the satisfaction of desires or preferences. They go on to insist that moral action is rational for a person to perform if and only if such action advances the satisfaction of his desires or preferences. And they argue that because moral action leads to peaceful and harmonious living conducive to the satisfaction of almost everyone's desires or preferences, moral actions are rational for almost everyone and thus "mutually agreeable." But Hobbesians believe that, to ensure that no cooperative person becomes the prey of immoral aggressors, moral actions must be the conventional norms in a community, so that each person can expect that if she behaves cooperatively, others will do so too. These conventions constitute the institution of morality in a society.

So the Hobbesian moral theory is committed to the idea that morality is a human-made institution, which is justified only to the extent that it effectively furthers human interests. Hobbesians explain the existence of morality in society by appealing to the convention-creating activities of human beings, while arguing that the *justification* of morality in any human society depends upon how well its moral conventions serve individuals' desires or preferences. By considering "what we *could* agree to" if we reappraised and redid the cooperative conventions in our society, we can determine the extent to which our present conventions are "mutually agreeable" and so rational for us to accept and act on. Thus, Hobbesians invoke both actual agreements (or rather, conventions) and hypothetical agreements (which involve considering what conventions would be "mutually agreeable") at different points in their theory; the former are what they believe our moral life consists in; the latter are what they believe our moral life *should* consist in – i.e., what our actual moral life should model. So the notion of the contract does not do justificational work *by itself* in the Hobbesian moral theory: this term is used only metaphorically. What we "could agree to" has moral force for the Hobbesians not because make-believe promises in hypothetical worlds have any binding force but because this sort of agreement is a device that (merely) reveals how the agreed-upon outcome is rational for all of us. In particular, thinking about "what we could all agree to" allows us to construct a deduction of practical reason to determine what policies are mutually advantageous.

The second kind of contractarian theory is derived from the moral theorizing of Kant. In his later writings Kant proposed that the "idea" of the "Original Contract" could be used to determine what policies for a society would be just. When Kant asks "What could people agree to?" he is not trying to justify actions or policies by invoking, in any literal sense, the consent of the people. Only the consent of *real* people can be legitimating, and Kant talks about hypothetical agreements made by hypothetical people. But he does believe these make-believe agreements have moral force for us because the process by which these people reach agreement is morally revealing.

Kant's contracting process has been further developed by subsequent philosophers, such as Rawls, who concentrates on defining the hypothetical people who are supposed to make this agreement so that their reasoning will not be tarnished by immorality, injustice, or prejudice, thus ensuring that the outcome of their joint deliberations will be morally sound. Those contractarians who disagree with Rawls define the contracting parties in different ways, thereby getting different results. The Kantians' social contract is therefore a *device* used in their theorizing to *reveal* what is just or what is moral. So like Hobbesians, their contract talk is really just a way of reasoning that allows us to work out conceptual answers to moral problems. But whereas the Hobbesians' use of contract language expresses the fact that, on their view, morality is a human invention which (if it is well invented) ought to be mutually advantageous, the Kantians' use of the contract language is meant to show that moral principles and conceptions are provable theorems derived from a morally revealing and authoritative reasoning process or "moral proof procedure" that makes use of the social contract idea.

Both kinds of contractarian theory are individualistic, in the sense that they assume that moral and political policies must be justified with respect to, and answer the needs of, individuals. Accordingly, these theories have been criticized by communitarian philosophers, who argue that moral and political policies can and should be decided on the basis of what is best for a community. They are also attacked by utilitarian theorists, whose criterion of morality is the maximization of the utility of the community, and not the mutual satisfaction of the needs or preferences of individuals. Contractarians respond that whereas utilitarianism fails to take seriously the distinction between persons, contractarian theories make moral and political policies answerable to the legitimate interests and needs of individuals, which, contra the communitarians, they take to be the starting point of moral theorizing.

contradiction. See TRUTH TABLE.

contradiction, pragmatic. See PRAGMATIC CONTRADICTION.

contradiction, principle of. See PRINCIPLE OF CONTRADICTION.

contradictories. See SQUARE OF OPPOSITION.

contraposition, the immediate logical operation on any categorical proposition that is accomplished by first forming the complements of both the subject term and the predicate term of that proposition and then interchanging these complemented terms. Thus, contraposition applied to the categorical proposition 'All cats are felines' yields 'All non-felines are non-cats', where 'non-feline' and 'non-cat' are, respectively, the complements (or complementary terms) of 'feline' and 'cat'. The result of applying contraposition to a categorical proposition is said to be the contra-positive of that proposition. **See also** **SQUARE OF OPPOSITION**, **SYLLOGISM**. R.W.B.

contrapositive. See CONTRAPOSITION.

contraries, any pair of propositions that cannot both be true but can both be false; derivatively, any pair of properties that cannot both apply to a thing but that can both fail to apply to a thing. Thus the propositions 'This object is red all over' and 'This object is green all over' are contraries, as are the properties of being red all over and being green all over. Traditionally, it was considered that the categorical A-proposition 'All *S*'s are *P*'s' and the categorical E-proposition 'No *S*'s are *P*'s' were contraries; but according to De Morgan and most subsequent logicians, these two propositions are both true when there are no *S*'s at all, so that modern logicians do not usually regard the categorical A- and E-propositions as true contraries. **See also** **EXISTENTIAL IMPORT**, **SQUARE OF OPPOSITION**, **SYLLOGISM**. R.W.B.

contrary-to-duty imperative. See DEONTIC PARADOXES.

contrary-to-fact conditional. See COUNTERFACTUALS.

contravalid, designating a proposition *P* in a logical system such that every proposition in the system is a consequence of *P*. In most of the typical and familiar logical systems, contravalidity coincides with self-contradictoriness. **See also** **IMPLICATION**. R.W.B.

contributive value. See VALUE.

contributory value. See VALUE.

control, an apparently causal phenomenon closely akin to power and important for such topics as intentional action, freedom, and moral responsibility. Depending upon the control you had over the event, your finding a friend's stolen car may or may not be an intentional action, a free action, or an action for which you deserve moral credit. Control seems to be a causal phenomenon. Try to imagine controlling a car, say, without causing anything. If you cause nothing, you have no effect on the car, and one does not control a thing on which one has no effect. But control need not be causally deterministic. Even if a genuine randomizer in your car's steering mechanism gives you only a 99 percent chance of making turns you try to make, you still have considerable control in that sphere. Some philosophers claim that we have no control over anything if causal determinism is true. That claim is false. When you drive your car, you normally are in control of its speed and direction, even if our world happens to be deterministic. **See also** **DETERMINISM, FREE WILL PROBLEM, LUCK, POWER.** A.R.M.

convention. See LEWIS, DAVID.

conventional implicature. See IMPLICATURE.

conventionalism, the philosophical doctrine that logical truth and mathematical truth are created by our choices, not dictated or imposed on us by the world. The doctrine is a more specific version of the linguistic theory of logical and mathematical truth, according to which the statements of logic and mathematics are true because of the way people use language. Of course, any statement owes its truth to some extent to facts about linguistic usage. For example, 'Snow is white' is true (in English) because of the facts that (1) 'snow' denotes snow, (2) 'is white' is true of white things, and (3) snow is white. What the linguistic theory asserts is that statements of logic and mathematics owe their truth *entirely* to the way people use language. Extralinguistic facts such as (3) are not relevant to the truth of such statements. Which aspects of linguistic usage produce logical truth and mathematical truth? The conventionalist answer is: certain linguistic conventions. These conventions are said to include rules of inference, axioms, and definitions.

The idea that geometrical truth is truth we create by adopting certain conventions received support from the discovery of non-Euclidean geometries. Prior to this discovery, Euclidean geometry had been seen as a paradigm of a priori knowledge. The further discovery that these alternative systems are consistent made Euclidean geometry seem rejectable without violating rationality. Whether we adopt the Euclidean system or a non-Euclidean system seems to be a matter of our choice based on such pragmatic considerations as simplicity and convenience.

Moving to number theory, conventionalism suffered a prima facie setback with the discovery that arithmetic is incomplete if consistent. For let S be an *undecidable* sentence – i.e., a sentence for which there is neither proof nor disproof. Suppose S is true. In what conventions does its truth consist? Not axioms, rules of inference, and definitions. For if its truth consisted in these items it would be provable. Suppose S is not true. Then its negation must be true. In what conventions does *its* truth consist? Again, no answer. It appears that if S is true or its negation is true and if neither S nor its negation is provable, then not all arithmetic truth is truth by convention. A response the conventionalist could give is that neither S nor its negation is true if S is undecidable. That is, the conventionalist could claim that arithmetic has truth-value gaps.

As to logic, all truths of classical logic are provable and, unlike the case of number theory and geometry, axioms are dispensable. Rules of inference suffice. As with geometry, there are alternatives to classical logic. The intuitionist, e.g., does not accept the rule 'From not-not-A infer A'. Even detachment – 'From A, if A then B, infer B' – is rejected in some multivalued systems of logic. These facts support the conventionalist doctrine that adopting any set of rules of inference is a matter of our choice based on pragmatic considerations. But (the anti-conventionalist might respond) consider a simple logical truth such as 'If Tom is tall, then Tom is tall'. Granted that this is provable by rules of inference from the empty set of premises, why does it follow that its truth is not imposed on us by extralinguistic facts about Tom? If Tom is tall the sentence is true because its consequent is true. If Tom is not tall the sentence is true because its antecedent is false. In either case the sentence owes its truth to facts about Tom.

conventional sign. See THEORY OF SIGNS.

convention T, a criterion of material adequacy (of proposed truth definitions) discovered, formally articulated, adopted, and so named by Tarski in connection with his 1929 definition of the concept of truth in a formalized language. Convention T is one of the most important of several independent proposals Tarski made concerning philosophically sound and logically precise treatment of the concept of truth. Various of these proposals have been criticized, but convention T has remained virtually unchallenged and is regarded almost as an axiom of analytic philosophy. To say that a proposed definition of an established concept is materially adequate is to say that it is "neither too broad nor too narrow" – i.e., that the concept it characterizes is coextensive with the established concept. Since, as Tarski emphasized, for many formalized languages there are no criteria of truth, it would seem that there can be no general criterion of material adequacy of truth definitions. But Tarski brilliantly finessed this obstacle by discovering a specification that is fulfilled by the established correspondence concept of truth and that has the further property that any two concepts fulfilling it are necessarily coextensive. Basically, convention T requires that to be materially adequate a proposed truth definition must imply all of the infinitely many relevant Tarskian biconditionals; e.g., the sentence 'Some perfect number is odd' is true if and only if some perfect number is odd. Loosely speaking, a Tarskian biconditional for English is a sentence obtained from the form 'The sentence ________ is true if and only if _________' by filling the right blank with a sentence and filling the left blank with a name of the sentence. Tarski called these biconditionals "equivalences of the form T" and referred to the form as a "scheme." Later writers also refer to the form as "schema T." **See also** FORMAL SEMANTICS, GÖDEL'S INCOMPLETENESS THEOREMS, MATERIAL ADEQUACY, SATISFACTION, TARSKI, TRUTH. J.Cor.

convergence. See PHILOSOPHY OF SCIENCE.

conversational implicature. See IMPLICATURE.

converse. (1) Narrowly, the result of the immediate logical operation called *conversion* on any categorical proposition, accomplished by interchanging the subject term and the predicate term of that proposition. Thus, the converse of the categorical proposition 'All cats are felines' is 'All felines are cats'. (2) More broadly, the proposition obtained from a given 'if . . . then . . .' (conditional) proposition by interchanging the antecedent and the consequent clauses – i.e., the propositions following the 'if' and the 'then', respectively; also, the argument obtained from an argument of the form '*P*; therefore *Q*' by interchanging the premise and the conclusion. **See also** RELATION. R.W.B.

converse, outer and inner, respectively, the result of "converting" the two "terms" *or* the relation verb of a relational sentence. The outer converse of 'Abe helps Ben' is 'Ben helps Abe' and the inner converse is 'Abe is helped by Ben'. In simple, or atomic, sentences the outer and inner converses express logically equivalent propositions, and thus in these cases no informational ambiguity arises from the adjunction of 'and conversely' or 'but not conversely', despite the fact that such adjunction does not indicate which, if either, of the two converses intended is meant. However, in complex, or quantified, relational sentences such as 'Every integer precedes some integer' genuine informational ambiguity is produced. Under normal interpretations of the respective sentences, the outer converse expresses the false proposition that some integer precedes every integer, the inner converse expresses the true proposition that every integer is preceded by some integer. More complicated considerations apply in cases of quantified doubly relational sentences such as 'Every integer precedes every integer exceeding it'. The concept of scope explains such structural ambiguity: in the sentence 'Every integer precedes some integer and conversely', 'conversely' taken in the outer sense has wide scope, whereas taken in the inner sense it has narrow scope. **See also** AMBIGUITY, CONVERSE, RELATION, SCOPE. J. Cor.

converse domain. See RELATION.

converse relation. See RELATION.

conversion. See CONVERSE.

conviction, a belief or judgment (particularly moral, social, political, or religious) marked by a high degree of confidence. Some convictions embody or manifest an emotional commitment (associated with high confidence, sometimes central to one's sense of identity, often tied to one's moral values, and implying behavioral tendencies). Convictions, by contrast with mere beliefs, may also manifest ego involvement (say, being frequently thought about, doggedly held, considered important for some issue of substantial concern, and tied to feelings).

Convictions commonly also result from or are otherwise connected with cognitive elaboration, for instance being long held, central to one's overall views, thought to have far-reaching consequences, to be grounded in knowledge, or to be readily explained. Often, 'conviction' is used interchangeably with other terms, including 'extreme confidence', 'surety', 'high degree of belief', and 'certainty'. However, many important psychological and philosophical properties should be distinguished here: (1) the physiologically based strong feeling associated with a belief taken to express an intuitive estimate of likely truth (this feeling is probably best identified by 'confidence'); (2) the endorsement of one's belief as very likely true or accurate (most frequently, this is a conscious event involving a confident affirmation of the proposition in question, taken as indicating likely truth; this endorsement is probably best identified by 'surety'); (3) the idealized numerical measure of an estimate of likely truth or accuracy (generally identified by 'degree of belief', a term that encompasses "weak conviction" as well as conviction as most often understood); (4) a range of epistemic attitudes such as considering a proposition beyond rational doubt, conclusively supported by one's evidence, and the like. The term 'certainty' (in its psychological sense) is best reserved for some such property. **See also** BELIEF, BELIEF UPDATING, CERTAINTY, DEGREE OF BELIEF. W.J.M.

Conway, Anne (c.1630–79), English philosopher whose *Principia Philosophiae Antiquissimae et Recentissimae* (1690; English translation, *The Principles of the Most Ancient and Modern Philosophy*, 1692) proposes a monistic ontology in which all created things are modes of one spiritual substance emanating from God. This substance is made up of an infinite number of hierarchically arranged spirits, which she calls *monads*. Matter is congealed spirit. Motion is conceived not dynamically but vitally. Lady Conway's scheme entails a moral explanation of pain and the possibility of universal salvation. She repudiates the dualism of both Descartes and her teacher, Henry More, as well as the materialism of Hobbes and Spinoza. The work shows the influence of cabalism and affinities with the thought of the mentor of her last years, Francis Mercurius van Helmont, through whom her philosophy became known to Leibniz. S.H.

Cook Wilson, John. See WILSON.

Cooper, John M. (b.1939), American philosopher who has written mainly on ancient Greek and Roman philosophy, emphasizing the interpretation of texts in the light of their philosophical, historical, and cultural contexts, and vigorously defending the resulting philosophical doctrines as contributions to philosophy. He has had a lifelong engagement with Plato, starting with his Harvard Ph.D. (1967) on the *Theaetetus* (published 1990); in 1997 he edited *Plato: Complete Works*, the standard translation used by scholars. In *Reason and Human Good in Aristotle* (1975) he argued that the practical syllogism, far from representing a fragment of deliberation – an episode of conscious practical inference – instead represents the psychological meshing of an agent's decision (e.g., to abstain from eating sweets) with the content of the agent's occurrent perception (of a sweet thing) as being the explanation of the subsequent action (the abstention from eating that sweet thing). In "Aristotle on the Forms of Friendship" (included in the 1999 collection, *Reason and Emotion*) he rehabilitates Aristotle's theory of friendship by pointing out that it is a misunderstanding of Aristotle to think that only the rarefied form of friendship known as "virtue friendship" involves mutual "unself-interested well-wishing and well-doing"; the two lesser forms of friendship (pleasure and advantage friendships) do not involve "exclusively self-centered motivations" and are recognizable forms of friendship. Cooper has also made important contributions to the study of Hellenistic Philosophy (see, e.g., *Seneca: Moral and Political Essays*, 1995); his work on the Stoics is notable for its insistence that Stoic ethics cannot be understood except in the light of Stoic physics, including psychology (see, e.g., "Stoic Autonomy" in the 2004 collection, *Knowledge, Nature, and the Good*). *Pursuits of Wisdom: Six Ways of Life in Ancient Philosophy from Socrates to Plotinus* (2012), based on his 2011 John Locke Lectures, exemplifies his wide-ranging approach to ancient philosophy. B.Mor.

cooperation, a kind of joint action in which agents do something together: carry a table, build a bridge, form an association, write a joint paper, sing a song, etc. Not only single agents but also group agents may qualify as cooperators, but the focus here is on single agents. An adequate understanding of cooperation as joint action must clarify the latter in terms of shared intentional states and actions of the participants. The onus is on elucidating the word 'together', which may be understood either individualistically or collectivistically, depending on whether the agents are functioning in the private *I-mode* or the group-based *we-mode*. The we-mode concerns functioning as a member of a social group and taking directives from the group, whereas the I-mode concerns functioning as a private person, though possibly *in* a group context. The we-mode is inherently cooperative, whereas the I-mode is only contingently so, depending on the individual participants' mental states and dispositions.

I-Mode cooperation, in the two-person case such as carrying a table, involves adjusting one's means-actions and goals to the other participant's actions and goals so as to further both the other's goal satisfaction and one's own. In partial contrast, in we-mode cooperation, such as singing with a regular accompanist, participants see themselves as forming a social group and try as its members to advance its goals and interests (which are at least ideally also privately shared by them). They can, as with a choir, normally share a common reason for cooperation and are collectively committed to participating in the group's activities. The cooperative activities in both I-mode and we-mode cases proceed on the basis of relevant joint goals and intentions (involving the participants' shared "we-intentions" to participate), shared beliefs, and background as well as contextual assumptions.

The we-mode expresses a strong sense of cooperation that is not always at stake in cooperation. In a weaker sense, people may cooperate to contribute to a common goal that requires several persons' activities, such as freeing their bus from mud in order to continue their journey. The requirement for cooperation may also become institutionalized, especially when public goods are at issue, and within such collectively beneficial institutions both I-mode and we-mode cooperation may occur. A still wider account of cooperation must take account of authority and coercion, cooperation between institutional groups such as corporations and nations, as well as cooperation between higher-order groups such as the European Union.

coordination problem. See SOCIAL CHOICE THEORY.

coordinative definition. See DEFINITION.

Copernican revolution. See KANT.

copula, in logic, a form of the verb 'to be' that joins subject and predicate in singular and categorical propositions. In 'George is wealthy' and 'Swans are beautiful', e.g., 'is' and 'are', respectively, are copulas. Not all occurrences of forms of 'be' count as copulas. In sentences such as 'There are fifty-one states', 'are' is not a copula, since it does not join a subject and a predicate, but occurs simply as a part of the quantifier term 'there are'. **See also** DEFINITION, INTENSION, MEANING. copulatio. See PROPRIETATES TERMINORUM.

Cordemoy, Géraud de (1626–84), French philosopher and member of the Cartesian school. His most important work is his *Le discernement du corps et de l'âme en six discours*, published in 1666 and reprinted (under slightly different titles) a number of times thereafter. Also important are the *Discours physique de la parole* (1668), a Cartesian theory of language and communication; and *Une lettre écrite à un sçavant religieux* (1668), a defense of Descartes's orthodoxy on certain questions in natural philosophy. Cordemoy also wrote a history of France, left incomplete at his death.

Like Descartes, Cordemoy advocated a mechanistic physics explaining physical phenomena in terms of size, shape, and local motion, and held that minds are incorporeal thinking substances. Like most Cartesians, Cordemoy also advocated a version of occasionalism. But unlike other Cartesians, he argued for atomism and admitted the void. These innovations were not welcomed by other members of the Cartesian school. But Cordemoy is often cited by later thinkers, such as Leibniz, as an important seventeenth-century advocate of atomism. **See also** OCCASIONALISM. D.Garb.

Cornell Realism, a position in metaethics associated with the work of Richard Boyd, Nicholas Sturgeon, and David Brink. Cornell Realism gained prominence in the late 1980s as a result of several influential articles by Boyd and Sturgeon as well as Brink's book, *Moral Realism and the Foundations of Ethics*. While there is no official statement of the view, the following claims are often mentioned.

Cornell Realists accept cognitivism and moral realism. As a cognitivist view, Cornell Realism holds that moral judgments express cognitive states like beliefs rather than non-cognitive states like desires. As a version of moral realism, it holds that moral facts exist, and those facts are in some sense mind-independent. The view is standardly contrasted with other positions in metaethics such as expressivism, error theories, and constructivism.

Cornell Realism is also associated with naturalistic versions of moral realism. On one characterization, moral naturalism is the view that moral properties are investigable empirically by the sciences. Cornell Realists can accept naturalism so understood while remaining neutral about whether these properties are or are not identical to descriptive properties. Brink has posited a non-reductive constitution relation, which still counts as a form of naturalism so long as the supervening moral properties themselves are amenable to scientific inquiry.

Semantically, Cornell Realists deny that moral predicates and sentences are analyzable by necessary and sufficient conditions which employ only descriptive and no moral terms. This sets the view apart from *analytic functionalism*, a version of naturalist moral realism developed by Jackson. It is also intended to avoid Moore's naturalistic fallacy. Motivationally, Cornell Realists tend to reject motivational internalism, understood as positing a conceptually necessary connection between moral judgments and motivation. Instead, 'amoralists' – agents who can make a moral judgment and not be motivated at all by it – are conceptually possible.

corner quotes. See CORNERS.

corners, also called corner quotes, quasi-quotes, a notational device (⌐ ¬) introduced by Quine (*Mathematical Logic*, 1940) to provide a conveniently brief way of speaking generally about unspecified expressions of such and such kind. For example, a logician might want a conveniently brief way of saying in the metalanguage that the result of writing a wedge '∨' (the dyadic logical connective for a truth-functional use of 'or') between any two well-formed formulas (wffs) in the object language is itself a wff. Supposing the Greek letters 'ϕ' and 'ψ' are available in the metalanguage as variables ranging over wffs in the object language, it is tempting to think that the formation rule stated above can be succinctly expressed simply by saying that if ϕ and ψ are wffs, then 'ϕ ∨ ψ' is a wff. But this will not do, for 'ϕ ∨ ψ' is not a wff. Rather, it is a hybrid expression of two variables of the metalanguage and a dyadic logical connective of the object language. The problem is that putting quotation marks around the Greek letters merely results in designating those letters themselves, not, as desired, in designating the context of the unspecified wffs. Quine's device of corners allows one to transcend this limitation of straight quotation since quasi-quotation, e.g. ⌐ϕ ∨ ψ¬, amounts to quoting the constant contextual background, '# ∨ #', and imagining the unspecified expressions ϕ and ψ written in the blanks. **See also** **USE-MENTION DISTINCTION.** R.F.G.

correspondence theory of truth. See TRUTH.

corresponding conditional (of a given argument), any conditional whose antecedent is a (logical) conjunction of all of the premises of the argument and whose consequent is the conclusion. The two conditionals 'If Abe is Ben and Ben is wise, then Abe is wise' and 'If Ben is wise and Abe is Ben, then Abe is wise' are the two corresponding conditionals of the argument whose premises are 'Abe is Ben' and 'Ben is wise' and whose conclusion is 'Abe is wise'. For a one-premise argument, the corresponding conditional is the conditional whose antecedent is the premise and whose consequent is the conclusion. The limiting cases of the empty and infinite premise sets are treated in different ways by different logicians; one simple treatment considers such arguments to be lacking corresponding conditionals.

The *principle of corresponding conditionals* is that in order for an argument to be valid it is necessary and sufficient for all its corresponding conditionals to be tautological. The commonly used expression 'the corresponding conditional of an argument' is also used when two further stipulations are in force: first, that an argument is construed as having an (ordered) sequence of premises rather than an (unordered) set of premises; second, that conjunction is construed as a polyadic operation that produces in a unique way a single premise from a sequence of premises rather than as a dyadic operation that combines premises two by two. Under these stipulations the *principle of the corresponding conditional* is that in order for an argument to be valid it is necessary and sufficient for its corresponding conditional to be valid. These principles are closely related to *modus ponens*, to conditional proof, and to the so-called deduction theorem.

cosmological argument. See PHILOSOPHY OF RELIGION.

cosmology. See METAPHYSICS.

cosmopolitanism, the view that all persons in the world constitute a single moral community and that this fact carries strong normative implications independent of any smaller societies. The idea was initially developed by the Stoics (*kosmopolitês* is Greek for 'citizen of the world'), whose belief in natural law entailed universal moral norms with priority over more local affiliations, and given influential articulation in the modern age by Kant. Two primary senses can be distinguished. As a moral notion, cosmopolitanism recognizes individuals as the ultimate units of moral concern and so challenges the view that rights and duties substantially depend on one's membership within groups such as nations, clans, and ethnic communities. As a political notion, cosmopolitanism stresses the importance of institutions operating above the level of individual states. The demand for a world state is the strongest such claim, but most political cosmopolitans recommend more modest supranational institutions.

Views that ground rights and duties in communal or group membership thus challenge the main thrust of moral cosmopolitanism. The most important such view within political theory is *nationalism*, which insists that citizens may press special claims against their co-nationals and owe special duties to them and their national community. The strongest version of cosmopolitanism would deny that shared nationality creates moral obligations of any intrinsic weight (though it can grant such relations derivative moral importance), while less robust versions can allow some such obligations alongside the moral duties each human being owes to all others.

A final notion of cosmopolitanism refers to a conception of the self built around exposure to different ways of life and the rejection of a fixed identity rooted exclusively in one culture. This sense of cosmopolitanism figures prominently in debates over multiculturalism and minority rights but is less significant in moral and political theory generally than the other two notions. D.Mc.

cost-benefit analysis. See DECISION THEORY.

Cottingham, John (b.1943), English moral philosopher, philosopher of religion, and scholar of the early modern period, with substantial contributions to scholarship on the rationalists and Descartes. He is coeditor and translator of *The Philosophical Writings of Descartes*, the standard edition of Descartes's philosophy (1985–91), and editor of *The Cambridge Companion to Descartes* (1992). *Descartes* (1986), *The Rationalists* (1988), and *Cartesian Reflections* (2008) all present a subtle and sympathetic interpretation of Descartes's controversial views on mind and body. Cottingham's moral philosophy includes papers and an influential coedited volume (2010) on partiality and impartiality, from an Aristotelian perspective. More recent work, situated in the ancient Greek and Christian traditions of spiritual practices, focuses on flourishing and meaningful life. *Philosophy and the Good Life* (1998) brings together Descartes, psychoanalysis, and ancient philosophy, arguing that philosophical understanding of the good life must engage a broadly psychoanalytic approach to the emotions and the unconscious. *On the Meaning of Life* (2003) combines moral, aesthetic, and religious insights and focuses on religious *praxis*, thereby contrasting with the emphasis on beliefs prominent in his *Spiritual Dimension* (2005), *The Meaning of Theism* (2007), and *Why Believe?* (2009). Cottingham's work emphasizes philosophy as a 'humanistic' discipline and eschews inappropriate technical and scientific models for a view of philosophy as engaged, holistically and non-reductively, with what it means to be human. **See also** **DESCARTES, PHILOSOPHY OF RELIGION, RATIONALISM.** S.V.

counterfactual analysis of causation. See CAUSATION.

counterfactuals, also called contrary-to-fact conditionals, subjunctive conditionals that presuppose the falsity of their antecedents, such as 'If Hitler had invaded England, Germany would have won' and 'If I were you, I'd run'.

Conditionals (or hypothetical statements) are compound statements of the form 'If *p*, (then) *q*', or equivalently '*q* if *p*'. Component *p* is described as the antecedent (protasis) and *q* as the consequent (apodosis). A conditional like 'If Oswald *did not* kill Kennedy, then someone else *did*' is called indicative, because both the antecedent and consequent are in the indicative mood. One like 'If

Oswald *had not* killed Kennedy, then someone else *would have*' is subjunctive. Many subjunctive and all indicative conditionals are *open*, presupposing nothing about the antecedent. Unlike 'If Bob had won, he'd be rich', neither 'If Bob should have won, he would be rich' nor 'If Bob won, he is rich' implies that Bob did not win. Counterfactuals presuppose, rather than assert, the falsity of their antecedents. 'If Reagan had been president, he would have been famous' seems inappropriate and out of place, but not false, given that Reagan was president. The difference between counterfactual and open subjunctives is less important logically than that between subjunctives and indicatives. Whereas the indicative conditional about Kennedy is true, the subjunctive is probably false. Replace 'someone' with 'no one' and the truth-values reverse.

The most interesting logical feature of counterfactuals is that they are not truth-functional. A truth-functional compound is one whose truth-value is completely determined in every possible case by the truth-values of its components. For example, the falsity of 'The president is a grandmother' and 'The president is childless' logically entails the falsity of 'The president is a grandmother and childless': *all* conjunctions with false conjuncts are false. But whereas 'If the president were a grandmother, the president would be childless' is false, other counterfactuals with equally false components are true, such as 'If the president were a grandmother, the president would be a mother'. The truth-value of a counterfactual is determined in part by the specific *content* of its components. This property is shared by indicative and subjunctive conditionals generally, as can be seen by varying the wording of the example. In marked contrast, the material conditional, $p \supset q$, of modern logic, defined as meaning that either p is false or q is true, is completely truth-functional. 'The president is a grandmother $\supset$ The president is childless' is just as true as 'The president is a grandmother $\supset$ The president is a mother'. While stronger than the material conditional, the counterfactual is weaker than the strict conditional, $p \rightarrow q$, of modern modal logic, which says that $p \supset q$ is *necessarily* true. 'If the switch had been flipped, the light would be on' may in fact be true even though it is possible for the switch to have been flipped without the light's being on because the bulb could have burned out.

The fact that counterfactuals are neither strict nor material conditionals generated the *problem of counterfactual conditionals* (raised by Chisholm and Goodman): what are the truth conditions of a counterfactual, and how are they determined by its components? According to the "metalinguistic" approach, which resembles the deductive-nomological model of explanation, a counterfactual is true when its antecedent conjoined with *laws of nature* and statements of *background conditions* logically entails its consequent. On this account, 'If the switch had been flipped the light would be on' is true because the statement that the switch was flipped, plus the laws of electricity and statements describing the condition and arrangement of the circuitry, entail that the light is on. The main problem is to specify *which* facts are "fixed" for any given counterfactual and context. The background conditions cannot include the denials of the antecedent or the consequent, even though they are true, nor anything else that would not be true if the antecedent were. Counteridenticals, whose antecedents assert identities, highlight the difficulty: the background for 'If I were you, I'd run' must include facts about my character and your situation, but not vice versa. Counterlegals like 'Newton's laws would fail if planets had rectangular orbits', whose antecedents deny laws of nature, show that even the set of laws cannot be all-inclusive.

Another leading approach (pioneered by Stalnaker and David Lewis) extends the possible-worlds semantics developed for modal logic, saying that a counterfactual is true when its consequent is true in the *nearest possible world* in which the antecedent is true. The counterfactual about the switch is true on this account provided a world in which the switch was flipped and the light is on is closer to the actual world than one in which the switch was flipped but the light is not on. The main problem is to specify which world is nearest for any given counterfactual and context. The difference between indicative and subjunctive conditionals can be accounted for in terms of either a different set of background conditions or a different measure of nearness.

Counterfactuals turn up in a variety of philosophical contexts. To distinguish *laws* like 'All copper conducts' from equally true generalizations like 'Everything in my pocket conducts', some have observed that while anything *would* conduct if it *were* copper, not everything would conduct if it were in my pocket. And to have a *disposition* like solubility, it does not suffice to be either dissolving or not in water: it must in addition be true that the object would dissolve if it were in water. It has similarly been suggested that one event is the *cause* of another only if the latter would not have occurred if the former had not; that an action is *free* only if the agent could or would have done otherwise if he had wanted to; that a person is in a particular *mental state* only if he would behave in certain ways given certain stimuli; and that an action is *right* only if a completely rational and fully informed agent would choose it.

See also CAUSATION, POSSIBLE WORLDS.

W.A.D.

counteridenticals. See COUNTERFACTUALS.

counterinstance, also called counterexample. (1) A particular instance of an argument form that has all true premises but a false conclusion, thereby showing that the form is not universally valid. The argument form '$p \vee q$, $\sim p$ / $\therefore \sim q$', e.g., is shown to be invalid by the counterinstance 'Grass is either red or green; Grass is not red; Therefore, grass is not green'. (2) A particular false instance of a statement form, which demonstrates that the form is not a logical truth. A counterinstance to the form '$(p \vee q) \supset p$', e.g., would be the statement 'If grass is either red or green, then grass is red'. (3) A particular example that demonstrates that a universal generalization is false. The universal statement 'All large cities in the United States are east of the Mississippi' is shown to be false by the counterinstance of San Francisco, which is a large city in the United States that is not east of the Mississippi. V.K.

counterintuitive, the property of seeming, at least pretheoretically, false, implausible, contrary to ordinary expectations, or in conflict with what we feel a conscious inclination to believe. Solipsism, e.g., strikes many people as counterintuitive, as would reports of the sighting of a married bachelor. The failure of a proposed analysis to cohere with or account for widely shared intuitions can count against it. However, there is disagreement about just when and to what extent we ought to defer to, rather than alter, our intuitions. Whether an idea seems counterintuitive – like the earth's rotating on its axis at more than a thousand miles per hour – can depend on background beliefs or the availability of concepts, such as inertia. Moreover, aspects of our best scientific theories, including quantum mechanics and general relativity, are deeply counterintuitive and often remain so for physicists immersed in the perspectives of these theories.

Seeming counterintuitive admits of degree with respect to both the number of intuitions violated and the extent to which they are violated. The proposition that there is a talking horse is counterintuitive, but less so than that there is one that also rides a bicycle and cooks spaghetti. Some empirical research in cognitive science of religion suggests that, other things being equal, concepts that are minimally counterintuitive in the sense that they strain against a handful of specific intuitions (e.g., survival after death or the concept of a non-embodied person) but otherwise largely conform to our expectations about reality are more easily remembered and culturally transmitted than those that are either intuitive or massively counterintuitive.

See also A PRIORI, COGNITIVE SCIENCE OF RELIGION, EPISTEMOLOGY, INTUITION. D.J.M.

counterpart theory, a theory that analyzes statements about what is possible and impossible for individuals (statements of *de re* modality) in terms of what holds of *counterparts* of those individuals in other possible worlds, a thing's counterparts being individuals that resemble it without being identical with it. (The name 'counterpart theory' was coined by David Lewis, the theory's principal exponent.) Whereas some theories analyze 'Mrs. Simpson might have been queen of England' as 'In some possible world, Mrs. Simpson is queen of England', counterpart theory analyzes it as 'In some possible world, a counterpart of Mrs. Simpson is queen of (a counterpart of) England'. The chief motivation for counterpart theory is a combination of two views: (a) *de re* modality should be given a possible-worlds analysis, and (b) each actual individual exists only in the actual world, and hence cannot exist with different properties in other possible worlds. Counterpart theory provides an analysis that allows 'Mrs. Simpson might have been queen' to be true compatibly with (a) and (b). For Mrs. Simpson's counterparts in other possible worlds, in those worlds where she herself does not exist, may have regal properties that the actual Mrs. Simpson lacks. Counterpart theory is perhaps prefigured in Leibniz's theory of possibility. **See also** COUNTERFACTUALS, POSSIBLE WORLDS.

P.Mac.

count noun, a noun that can occur syntactically (a) with quantifiers 'each', 'every', 'many', 'few', 'several', and numerals; (b) with the indefinite article, 'a(n)'; and (c) in the plural form. The following are examples of count nouns (CNs), paired with semantically similar *mass nouns* (MNs): 'each dollar / silver', 'one composition / music', 'a bed / furniture', 'instructions / advice'. MNs but not CNs can occur with the quantifiers 'much' and 'little': 'much poetry / poem(s)', 'little bread / loaf'. Both CNs and MNs may occur with 'all', 'most', and 'some'. Semantically, CNs but not MNs refer distributively, providing a counting criterion. It makes sense to ask how many CNs?: 'How many coins / gold?' MNs but not CNs refer collectively. It makes sense to ask how much MN?: 'How much gold / coins?'

One problem is that these syntactic and semantic criteria yield different classifications; another problem is to provide logical forms and truth conditions for sentences containing mass nouns. **See also** DISTRIBUTION, MEANING, SORTAL PREDICATE. W.K.W.

courage. See CARDINAL VIRTUES.

Cournot, Antoine-Augustin (1801–77), French mathematician and economist. A critical realist in scientific and philosophical matters, he was a conservative in religion and politics. His *Researches into the Mathematical Principles of the Theory of Wealth* (1838), though a fiasco at the time, pioneered mathematical economics. Cournot upheld a position midway between science and metaphysics. His philosophy rests on three basic concepts: order, chance, and probability. The *Exposition of the Theory of Chances and Probabilities* (1843) focuses on the calculus of probability, unfolds a theory of chance occurrences, and distinguishes among objective, subjective, and philosophical probability. The *Essay on the Foundations of Knowledge* (1861) defines science as logically organized knowledge. Cournot developed a probabilist epistemology, showed the relevance of probabilism to the scientific study of human acts, and further assumed the existence of a providential and complex order undergirding the universe. *Materialism, Vitalism, Rationalism* (1875) acknowledges transrationalism and makes room for finality, purpose, and God. J.-L.S.

Cousin, Victor (1792–1867), French philosopher who set out to merge the French psychological tradition with the pragmatism of Locke and Condillac and the inspiration of the Scottish (Reid, Stewart) and German idealists (Kant, Hegel). His early courses at the Sorbonne (1815–18), on "absolute" values that might overcome materialism and skepticism, aroused immense enthusiasm. The course of 1818, *Du Vrai, du Beauet, et du Bien* ("Of the True, the Beautiful, and the Good"), is preserved in the Adolphe Garnier edition of student notes (1836); other early texts appeared in the *Fragments philosophiques* ("Philosophical Fragments," 1826). Dismissed from his teaching post as a liberal (1820), arrested in Germany at the request of the French police, and detained in Berlin, he was released after Hegel intervened (1824); he was not reinstated until 1828. Under Louis-Philippe, he rose to highest honors, became minister of education, and introduced philosophy into the curriculum. His eclecticism, transformed into a spiritualism and cult of the "*juste milieu*," became the official philosophy. Cousin rewrote his work accordingly and even succeeded in having *Du Vrai* (3d ed. 1853) removed from the papal index. In 1848 he was forced to retire. He is noted for his educational reforms, as a historian of philosophy, and for his translations (Proclus, Plato), editions (Descartes), and portraits of ladies of seventeenth-century society. O.A.H.

Couturat, Louis (1868–1914), French philosopher and logician who wrote on the history of philosophy, logic, philosophy of mathematics, and the possibility of a universal language. Couturat refuted Renouvier's finitism and advocated an actual infinite in *The Mathematical Infinite* (1896). He argued that the assumption of infinite numbers was indispensable to maintaining the continuity of magnitudes. He saw a precursor of modern logistic in Leibniz, basing his interpretation of Leibniz on the *Discourse on Metaphysics* and Leibniz's correspondence with Arnauld. His epoch-making *Leibniz's Logic* (1901) describes Leibniz's metaphysics as *panlogism*. Couturat published a study on Kant's mathematical philosophy (*Revue de Métaphysique*, 1904), and defended Peano's logic, Whitehead's algebra, and Russell's logistic in *The Algebra of Logic* (1905). He also contributed to André Lalande's *Vocabulaire technique et critique de la philosophie* (1926). J.-L.S.

covering law model, the view of scientific explanation as a deductive argument which contains non-vacuously at least one universal law among its premises. The names of this view include 'Hempel's model', 'Hempel-Oppenheim (HO) model', 'Popper-Hempel model', 'deductive-nomological (D-N) model', and the 'subsumption theory' of explanation. The term 'covering law model of explanation' was proposed by William Dray.

The theory of scientific explanation was first developed by Aristotle. He suggested that science proceeds from mere knowing *that* to deeper knowing *why* by giving understanding of different things by the four types of causes. Answers to why-questions are given by scientific syllogisms – i.e., by deductive arguments with premises that are necessarily true and causes of their consequences. Typical examples are the "subsumptive" arguments that can be expressed by the Barbara syllogism:

All ravens are black.
Jack is a raven.
Therefore, Jack is black.

Plants containing chlorophyll are green.
Grass contains chlorophyll.
Therefore, grass is green.

In modern logical notation,

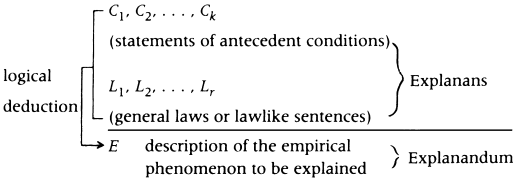
$$\begin{array}{l} \forall x(Fx \rightarrow Gx) \\ \underline{Fa \qquad\qquad} \\ Ga \end{array}$$

$$\begin{array}{l} \forall x(Fx \rightarrow Gx) \\ \underline{\forall x(Hx \rightarrow Fx)} \\ \forall x(Hx \rightarrow Gx). \end{array}$$

An explanatory argument was later called in Greek *synthesis*, in Latin *compositio* or *demonstratio propter quid*. After the seventeenth century, the terms 'explication' and 'explanation' became commonly used.

The nineteenth-century empiricists accepted Hume's criticism of Aristotelian essences and necessities: a law of nature is an extensional statement that expresses a uniformity – i.e., a constant conjunction between properties ('All swans are white') or types of events ('Lightning is always followed by thunder'). Still, they accepted the subsumption theory of explanation: "An individual fact is said to be explained by pointing out its cause, that is, by stating the law or laws of causation, of which its production is an instance," and "a law or uniformity in nature is said to be explained when another law or laws are pointed out, of which that law itself is but a case, and from which it could be deduced" (J. S. Mill). A general model of probabilistic explanation, with deductive explanation as a specific case, was given by Peirce in 1883.

A modern formulation of the subsumption theory was given by Hempel and Paul Oppenheim in 1948 by the following schema of D-N explanation:



$C_1, C_2, \ldots, C_k$
(statements of antecedent conditions)
logical deduction
$L_1, L_2, \ldots, L_r$
(general laws or lawlike sentences)
Explanans
E
description of the empirical phenomenon to be explained
Explanandum

Explanandum *E* is here a sentence that describes a known particular event or fact (singular explanation) or uniformity (explanation of laws). Explanation is an argument that answers an explanation-seeking why-question 'Why *E?*' by showing that *E* is nomically expectable on the basis of general laws ($r \geq 1$) and antecedent conditions. The relation between the explanans and the explanandum is logical deduction. Explanation is distinguished from other kinds of scientific systematization (prediction, postdiction) that share its logical characteristics – a view often called the *symmetry thesis* regarding explanation and prediction – by the presupposition that the phenomenon *E* is already known. This also separates explanations from reason-seeking arguments that answer questions of the form 'What reasons are there for believing that *E?*' Hempel and Oppenheim required that the explanans have empirical content – i.e., be testable by experiment or observation – and it must be true. If the strong condition of truth is dropped, we speak of *potential* explanation.

Dispositional explanations, for non-probabilistic dispositions, can be formulated in the D-N model. For example, let Hx = 'x is hit by hammer', Bx = 'x breaks', and Dx = 'x is fragile'. Then the explanation for why a piece of glass was broken may refer to its fragility and its being hit:

$$\begin{array}{l} \forall x(Hx \rightarrow (Dx \rightarrow Bx)) \\ \underline{Ha \,\&\, Da \qquad\qquad\quad} \\ Ba \end{array}$$

It is easy to find examples of HO explanations that are not satisfactory: self-explanations ('Grass is green, because grass is green'), explanations with too weak premises ('John died, because he had a heart attack or his plane crashed'), and explanations with irrelevant information ('This stuff dissolves in water, because it is sugar produced in Finland'). Attempts at finding necessary and sufficient conditions in syntactic and semantic terms for acceptable explanations have not led to any agreement. The HO model also needs the additional Aristotelian condition that causal explanation is directed from causes to effects. This is shown by Sylvain Bromberger's flagpole example: the length of a flagpole explains the length of its shadow, but not vice versa. Michael Scriven has argued against Hempel that explanations of particular events should be given by singular causal statements '*E* because *C*'. However, a regularity theory (Humean or stronger than Humean) of causality implies that the truth of such a singular causal statement presupposes a universal law of the form ‘Events of type *C* are universally followed by events of type *E*’.

The HO version of the covering law model can be generalized in several directions. The explanans may contain probabilistic or statistical laws. The explanans-explanandum relation may be inductive (in this case the explanation itself is inductive). This gives us four types of explanations: *deductive-universal* (i.e., D-N), *deductive-probabilistic, inductive-universal,* and *inductive-probabilistic* (I-P). Hempel’s 1962 model for I-P explanation contains a probabilistic covering law $P(G/F) = r$, where r is the statistical probability of G given F, and r in brackets is the inductive probability of the explanandum given the explanans:

$$\begin{array}{l} P(G/F) = r \\ Fa \\ \hline\hline Ga \end{array} \; [r]$$

The explanation-seeking question may be weakened from ‘Why necessarily *E?*’ to ‘How possibly *E?*’. In a *corrective explanation*, the explanatory answer points out that the explanandum sentence *E* is not strictly true. This is the case in *approximate explanation* (e.g., Newton’s theory entails a corrected form of Galileo’s and Kepler’s laws).

Craig reduct. See CRAIG’S INTERPOLATION THEOREM.

Craig’s interpolation theorem, a theorem for first-order logic: if a sentence ψ of first-order logic entails a sentence θ there is an “interpolant,” a sentence φ in the vocabulary common to θ and ψ that entails θ and is entailed by ψ. Originally William Craig proved his theorem in 1957 as a lemma, to give a simpler proof of Beth’s definability theorem, but the result now stands on its own. In abstract model theory, logics for which an interpolation theorem holds are said to have the Craig interpolation property. Craig’s interpolation theorem shows that first-order logic is closed under implicit definability, so that the concepts embodied in first-order logic are all given explicitly.

In the philosophy of science literature ‘Craig’s theorem’ usually refers to another result of Craig’s: that any recursively enumerable set of sentences of first-order logic can be axiomatized. This has been used to argue that theoretical terms are in principle eliminable from empirical theories. Assuming that an empirical theory can be axiomatized in first-order logic – i.e., that there is a recursive set of first-order sentences from which all theorems of the theory can be proved – it follows that the set of consequences of the axioms in an “observational” sublanguage is a recursively enumerable set. Thus, by Craig’s theorem, there is a set of axioms for this subtheory, the Craig reduct, that contains only observation terms. Interestingly, the Craig reduct theory may be semantically weaker, in the sense that it may have models that cannot be extended to a model of the full theory. The existence of such a model would prove that the theoretical terms cannot all be defined on the basis of the observational vocabulary only, a result related to Beth’s definability theorem.

creation *ex nihilo*, the act of bringing something into existence from nothing. According to traditional Christian theology, God created the world *ex nihilo*. To say that the world was created from nothing does not mean that there was a prior non-existent substance out of which it was fashioned, but rather that there was not anything out of which God brought it into being. However, some of the patristics influenced by Plotinus, such as Gregory of Nyssa, apparently understood creation *ex nihilo* to be an *emanation* from God according to which what is created comes, not from nothing, but from God himself. Not everything that God makes need be created *ex nihilo;* or if, as in Genesis 2:7, 19, God made a human being and animals from the ground, a previously existing material, God did not create them from nothing. Regardless of how bodies are made, orthodox theology holds that human souls are created *ex nihilo;* the opposing view, *traducianism,* holds that souls are propagated along with bodies. **See also** GREGORY OF NYSSA, PHILOSOPHY OF RELIGION, PLOTINUS. E.R.W.

creationism, acceptance of the early chapters of Genesis taken literally. Genesis claims that the universe and all of its living creatures, including humans, were created by God in the space of six days. The need to find some way of reconciling this story with the claims of science intensified in the nineteenth century, with the publication of Darwin's *Origin of Species* (1859). In the southern states of the United States, the indigenous form of evangelical Protestant Christianity declared total opposition to evolutionism, refusing any attempt at reconciliation and affirming total commitment to a literal "creationist" reading of the Bible. Because of this, certain states passed laws banning the teaching of evolutionism. More recently, literalists have argued that the Bible can be given full scientific backing, and they have therefore argued that "creation science" may properly be taught in state-supported schools in the United States without violation of the constitutional separation of church and state. This claim was challenged in the state of Arkansas in 1981, and ultimately rejected by the U.S. Supreme Court.

The creationism dispute has raised some issues of philosophical interest and importance. Most obviously, there is the question of what constitutes a genuine science. Is there an adequate *criterion of demarcation* between science and nonscience, and will it put evolutionism on the one side and creationism on the other? Some philosophers, arguing in the spirit of Karl Popper, think that such a criterion can be found. Others are not so sure; and yet others think that some such criterion can be found, but shows creationism to be genuine science, albeit already proved false.

Philosophers of education have also taken an interest in creationism and what it represents. If one grants that even the most orthodox science may contain a value component, reflecting and influencing its practitioners' culture, then teaching a subject like biology almost certainly is not a normatively neutral enterprise. In that case, without necessarily conceding to the creationist anything about the true nature of science or values, perhaps one must agree that science with its teaching is not something that can and should be set apart from the rest of society, as an entirely distinct phenomenon.

creationism, theological. See PREEXISTENCE.

creativity, a kind of ability or disposition to produce original and valuable things (artifacts, theories, concepts, etc.). The ability or disposition to produce something original, in the sense of saliently new, does not suffice for creativity, since, as Kant notes in discussing genius in the *Critique of Judgment*, there is such a thing as original nonsense. So a value condition on creativity is also required (Kant holds that the products of genius must also be "exemplary"), though the putative existence of a "dark side" to creativity, i.e. creativity exercised in immoral acts, poses a challenge to this claim. Not all ways of producing something saliently new and valuable count as creative, since one may produce something saliently new and valuable by mere luck or by using mechanical search methods involving no exercise of the understanding. Creativity arguably does not require the creation of something, since there are creative discoveries, such as those in science; but it can be replied that these count as creative only because they involve the creation of new theories or concepts.

Creativity is often associated (including by Kant) with the imagination, though not all exercises of imagination are creative (daydreaming and fantasies usually are not), nor arguably are all instances of creativity exercises of the imagination, for instance when one is suddenly inspired. Philosophers have disagreed about whether creativity is a rational or irrational disposition: Plato in *Ion* argues that poetic creativity is essentially irrational and does not involve the exercise of a skill, whereas Aristotle in the *Poetics* treats poetic creativity as a kind of skill that involves the exercise of means-end reasoning. Recently some philosophers, notably Margaret Boden, have proposed computational theories of creativity, while others have argued for Darwinian theories, on which creativity consists in the blind variation and selection retention of ideas.

credibility. See CARNAP.

Crescas, Hasdai (d.1412), Spanish Jewish philosopher, theologian, and statesman. He was a well-known representative of the Jewish community in both Barcelona and Saragossa. Following the death of his son in the anti-Jewish riots of 1391, he wrote a chronicle of the massacres (published as an appendix to Ibn Verga, *Shevet Yehudah*, ed. M. Wiener, 1855). Crescas's devotion to protecting Spanish Jewry in a time when conversion was encouraged is documented in one extant work, the *Refutation* *of Christian Dogmas* (1397–98), found in the 1451 Hebrew translation of Joseph ibn Shem Tov (*Bittul 'Iqqarey ha-Nofrim*). His major philosophical work, *Or Adonai* ("The Light of the Lord"), was intended as the first of a two-part project that was to include his own more extensive systematization of *halakha* (Jewish law) as well as a critique of Maimonides' work. But this second part, "Lamp of the Divine Commandment," was never written.

Or Adonai is a philosophico-dogmatic response to and attack on the Aristotelian doctrines that Crescas saw as a threat to the Jewish faith, doctrines concerning the nature of God, space, time, place, free will, and infinity. For theological reasons he attempts to refute basic tenets in Aristotelian physics. He offers, e.g., a critique of Aristotle's arguments against the existence of a vacuum. The Aristotelian view of time is rejected as well. Time, like space, is thought by Crescas to be infinite. Furthermore, it is not an accident of motion, but rather exists only in the soul. In defending the fundamental doctrines of the Torah, Crescas must address the question discussed by his predecessors Maimonides and Gersonides, namely that of reconciling divine foreknowledge with human freedom. Unlike these two thinkers, Crescas adopts a form of determinism, arguing that God knows both the possible and what will necessarily take place. An act is contingent with respect to itself, and necessary with respect to its causes and God's knowledge. To be willed freely, then, is not for an act to be absolutely contingent, but rather for it to be "willed internally" as opposed to "willed externally."

Reactions to Crescas's doctrines were mixed. Isaac Abrabanel, despite his respect for Crescas's piety, rejected his views as either "unintelligible" or "simple-minded." On the other hand, Giovanni Pico della Mirandola appeals to Crescas's critique of Aristotelian physics; Judah Abrabanel's *Dialogues of Love* may be seen as accommodating Crescas's metaphysical views; and Spinoza's notions of necessity, freedom, and extension may well be influenced by the doctrines of *Or Adonai*.

criteriological connection. See CRITERION.

criteriology. See MERCIER.

criterion, broadly, a sufficient condition for the presence of a certain property or for the truth of a certain proposition. Generally, a criterion need be sufficient merely in normal circumstances rather than absolutely sufficient. Typically, a criterion is salient in some way, often by virtue of being a necessary condition as well as a sufficient one. The plural form, 'criteria', is commonly used for a set of singly necessary and jointly sufficient conditions. A set of truth conditions is said to be criterial for the truth of propositions of a certain form. A conceptual analysis of a philosophically important concept may take the form of a proposed set of truth conditions for paradigmatic propositions containing the concept in question. Philosophers have proposed criteria for such notions as meaningfulness, intentionality, knowledge, justification, justice, rightness, and identity (including personal identity and event identity), among many others.

There is a special use of the term in connection with Wittgenstein's well-known remark that "an 'inner process' stands in need of outward criteria," e.g. moans and groans for aches and pains. The suggestion is that a *criteriological connection* is needed to forge a conceptual link between items of a sort that are intelligible and knowable to items of a sort that, but for the connection, would not be intelligible or knowable. A mere *symptom* cannot provide such a connection, for establishing a correlation between a symptom and that for which it is a symptom presupposes that the latter is intelligible and knowable. One objection to a criteriological view, whether about aches or quarks, is that it clashes with realism about entities of the sort in question and lapses into, as the case may be, behaviorism or instrumentalism. For it seems that to posit a criteriological connection is to suppose that the nature and existence of entities of a given sort can depend on the conditions for their intelligibility or knowability, and that is to put the epistemological cart before the ontological horse.

criterion, problem of the. See PROBLEM OF THE CRITERION.

Critical idealism. See KANT.

critical legal studies, a loose assemblage of legal writings and thinkers in the United States and Great Britain since the mid-1970s that aspire to a jurisprudence and a political ideology. Like the American legal realists of the 1920s and 1930s, the jurisprudential program is largely negative, consisting in the discovery of supposed contradictions within both the law as a whole and areas of law such as contracts and criminal law. The jurisprudential implication derived from such supposed contradictions within the law is that any decision in any case can be defended as following logically from some authoritative propositions of law, making the law completely without guidance in particular cases. Also like the American legal realists, the political ideology of critical legal studies is vaguely leftist, embracing the communitarian critique of liberalism. Communitarians fault liberalism for its alleged overemphasis on individual rights and individual welfare at the expense of the intrinsic value of certain collective goods. Given the cognitive relativism of many of its practitioners, critical legal studies tend not to aspire to have anything that could be called a theory of either law or of politics. **See also** JURISPRUDENCE, PHILOSOPHY OF LAW, POLITICAL PHILOSOPHY.

M.S.M.

critical philosophy. See BROAD, KANT.

Critical Realism, a philosophy that at the highest level of generality purports to integrate the positive insights of both New Realism and idealism. New Realism was the first wave of realistic reaction to the dominant idealism of the nineteenth century. It was a version of immediate and direct realism. In its attempt to avoid any representationalism that would lead to idealism, this tradition identified the immediate data of consciousness with objects in the physical world. There is no intermediary between the knower and the known. This heroic tour de force foundered on the phenomena of error, illusion, and perceptual variation, and gave rise to a successor realism – Critical Realism – that acknowledged the mediation of "the mental" in our cognitive grasp of the physical world.

"Critical Realism" was the title of a work in epistemology by Roy Wood Sellars (1916), but its more general use to designate the broader movement derives from the 1920 cooperative volume, *Essays in Critical Realism: A Cooperative Study of the Problem of Knowledge*, containing position papers by Durant Drake, A. O. Lovejoy, J. B. Pratt, A. K. Rogers, C. A. Strong, George Santayana, and Roy Wood Sellars. With New Realism, Critical Realism maintains that the primary object of knowledge is the independent physical world, and that what is immediately present to consciousness is not the physical object as such, but some corresponding mental state broadly construed. Whereas both New Realism and idealism grew out of the conviction that any such mediated account of knowledge is untenable, the Critical Realists felt that only if knowledge of the external world is explained in terms of a process of mental mediation can error, illusion, and perceptual variation be accommodated. One could fashion an account of mental mediation that did not involve the pitfalls of Lockean representationalism by carefully distinguishing between the object known and the mental state through which it is known.

The Critical Realists differed among themselves both epistemologically and metaphysically. The mediating elements in cognition were variously construed as essences, ideas, or sense-data, and the precise role of these items in cognition was again variously construed. Metaphysically, some were dualists who saw knowledge as unexplainable in terms of physical processes, whereas others (principally Santayana and Sellars) were materialists who saw cognition as simply a function of conscious biological systems. The position of most lasting influence was probably that of Sellars because that torch was taken up by his son, Wilfrid, whose very sophisticated development of it was quite influential.

C.F.D.

critical theory, any social theory that is at the same time explanatory, normative, practical, and self-reflexive. The term was first developed by Horkheimer as a self-description of the Frankfurt School and its revision of Marxism. It now has a wider significance to include any critical, theoretical approach, including feminism and liberation philosophy. When they make claims to be scientific, such approaches attempt to give rigorous explanations of the causes of oppression, such as ideological beliefs or economic dependence; these explanations must in turn be verified by empirical evidence and employ the best available social and economic theories. Such explanations are also normative and critical, since they imply negative evaluations of current social practices. The explanations are also practical, in that they provide a better self-understanding for agents who may want to improve the social conditions that the theory negatively evaluates. Such change generally aims at "emancipation," and theoretical insight empowers agents to remove limits to human freedom and the causes of human suffering. Finally, these theories must also be self-reflexive: they must account for their own conditions of possibility and for their potentially transformative effects. These requirements contradict the standard account of scientific theories and explanations, particularly positivism and its separation of fact and value. For this reason, the methodological writings of critical theorists often attack positivism and empiricism and attempt to construct alternative epistemologies. Critical theorists also reject relativism, since the cultural relativity of norms would undermine the basis of critical evaluation of social practices and emancipatory change.

The difference between critical and non-critical theories can be illustrated by contrasting the Marxian and Mannheimian theories of ideology. Whereas Mannheim's theory merely describes relations between ideas of social conditions, Marx's theory tries to show how certain social practices require false beliefs about them by their participants. Not only does Marx's theory explain why this is so, it also negatively evaluates those practices; it is practical in that by disillusioning participants, it makes them capable of transformative action. It is also self-reflexive, since it shows why some practices require illusions and others do not, and also why social crises and conflicts will lead agents to change their circumstances. It is scientific, in that it appeals to historical evidence and can be revised in light of better theories of social action, language, and rationality. Marx also claimed that his theory was superior for its special "dialectical method," but this is now disputed by most critical theorists, who incorporate many different theories and methods. This broader definition of critical theory, however, leaves a gap between theory and practice and places an extra burden on critics to justify their critical theories without appeal to such notions as inevitable historical progress. This problem has made critical theories more philosophical and concerned with questions of justification.

Croce, Benedetto (1866–1952), Italian philosopher. He was born at Pescasseroli, in the Abruzzi, and after 1886 lived in Naples. He briefly attended the University of Rome and was led to study Herbart's philosophy. In 1904 he founded the influential journal *La critica*. In 1910 he was made life member of the Italian senate. Early in his career he befriended Giovanni Gentile, but this friendship was breached by Gentile's Fascism. During the Fascist period and World War II Croce lived in isolation as the chief antifascist thinker in Italy. He later became a leader of the Liberal party and at the age of eighty founded the Institute for Historical Studies.

Croce was a literary and historical scholar who joined his great interest in these fields to philosophy. His best-known work in the English-speaking world is *Aesthetic as Science of Expression and General Linguistic* (1902). This was the first part of his "Philosophy of Spirit"; the second was his *Logic* (1905), the third his theory of the *Practical* (1909), and the fourth his *Historiography* (1917). Croce was influenced by Hegel and the Hegelian aesthetician Francesco De Sanctis (1817–83) and by Vico's conceptions of knowledge, history, and society. He wrote *The Philosophy of Giambattista Vico* (1911) and a famous commentary on Hegel, *What Is Living and What Is Dead in the Philosophy of Hegel* (1907), in which he advanced his conception of the "dialectic of distincts" as more fundamental than the Hegelian dialectic of opposites.

Croce held that philosophy always springs from the occasion, a view perhaps rooted in his concrete studies of history. He accepted the general Hegelian identification of philosophy with the history of philosophy. His philosophy originates from his conception of aesthetics. Central to his aesthetics is his view of intuition, which evolved through various stages during his career. He regards aesthetic experience as a primitive type of cognition. Intuition involves an awareness of a particular image, which constitutes a non-conceptual form of knowledge. Art is the expression of emotion but not simply for its own sake. The expression of emotion can produce cognitive awareness in the sense that the particular intuited as an image can have a cosmic aspect, so that in it the universal human spirit is perceived. Such perception is present especially in the masterpieces of world literature. Croce's conception of aesthetic has connections with Kant's "intuition" (*Anschauung*) and to an extent with Vico's conception of a primordial form of thought based in imagination (*fantasia*).

Croce's philosophical idealism includes fully developed conceptions of logic, science, law, history, politics, and ethics. His influence to date has been largely in the field of aesthetics and in historicist conceptions of knowledge and culture. His revival of Vico has inspired a whole school of Vico scholarship. Croce's conception of a "Philosophy of Spirit" showed it was possible to develop a post-Hegelian philosophy that, with Hegel, takes "the true to be the whole" but which does not simply imitate Hegel.

See also AESTHETICS, HEGEL, KANT, VICO. D.P.V.

crucial experiment, a means of deciding between rival theories that, providing parallel explanations of large classes of phenomena, come to be placed at issue by a single fact. For example, the Newtonian emission theory predicts that light travels faster in water than in air; according to the wave theory, light travels slower in water than in air. Dominique François Arago proposed a crucial experiment comparing the respective velocities. Léon Foucault then devised an apparatus to measure the speed of light in various media and found a lower velocity in water than in air. Arago and Foucault concluded for the wave theory, believing that the experiment refuted the emission theory. Other examples include Galileo's discovery of the phases of Venus (Ptolemaic vs. Copernican astronomy), Pascal's Puy-de-Dôme experiment with the barometer (vacuists vs. plenists), Fresnel's prediction of a spot of light in circular shadows (particle vs. wave optics), and Eddington's measurement of the gravitational bending of light rays during a solar eclipse (Newtonian vs. Einsteinian gravitation). At issue in crucial experiments is usually a novel prediction.

The notion seems to derive from Francis Bacon, whose *New Organon* (1620) discusses the "Instance of the Fingerpost" (*Instantia* – later *experimentum-crucis*), a term borrowed from the post set up at crossroads to indicate several directions. Crucial experiments were emphasized in early nineteenth-century scientific methodology – e.g., in John F. Herschel's *A Preliminary Discourse on the Study of Natural Philosophy* (1830). Duhem argued that crucial experiments resemble false dilemmas: hypotheses in physics do not come in pairs, so that crucial experiments cannot transform one of the two into a demonstrated truth. Discussing Foucault's experiment, Duhem asks whether we dare assert that no other hypothesis is imaginable and suggests that instead of light being either a simple particle or wave, light might be something else, perhaps a disturbance propagated within a dielectric medium, as theorized by Maxwell. In the twentieth century, crucial experiments and novel predictions figured prominently in the work of Imre Lakatos (1922–74). Agreeing that crucial experiments are unable to overthrow theories, Lakatos accepted them as retroactive indications of the fertility or progress of research programs.

Crusius, Christian August (1715–75), German philosopher, theologian, and devout Lutheran pastor who believed that religion was endangered by the rationalist views especially of Wolff. He devoted his considerable philosophical powers to working out acute and often deep criticisms of Wolff and developing a comprehensive alternative to the Wolffian system. His main philosophical works were published in the 1740s. In his understanding of epistemology and logic Crusius broke with many of the assumptions that allowed Wolff to argue from how we think of things to how things are. For instance, Crusius tried to show that the necessity in causal connection is not the same as logical necessity. He rejected the Leibnizian view that this world is probably the best possible world, and he criticized the Wolffian view of freedom of the will as merely a concealed spiritual mechanism.

His ethics stressed our dependence on God and his commands, as did the natural law theory of Pufendorf, but he developed the view in some strikingly original ways. Rejecting voluntarism, Crusius held that God's commands take the form of innate principles of the will (not the understanding). Everyone alike can know what they are, so (contra Wolff) there is no need for moral experts. And they carry their own motivational force with them, so there is no need for external sanctions. We have obligations of prudence to do what will forward our own ends; but true obligation, the obligation of virtue, arises only when we act simply to comply with God's law, regardless of any ends of our own. In this distinction between two kinds of obligation, as in many of his other views, Crusius plainly anticipated much that Kant came to think. Kant when young read and admired his work, and it is mainly for this reason that Crusius is now remembered.

Cudworth, Damaris, Lady Masham (1659–1708), English philosopher and author of two treatises on religion, *A Discourse Concerning the Love of God* (1690) and *Occasional Thoughts in Reference to a Virtuous Christian Life* (1705). The first argues against the views of the English Malebranchian John Norris; the second, ostensibly about the importance of education for women, argues for the need to establish natural religion on rational principles and explores the place of revealed religion within a rational framework. Cudworth's reputation is founded on her long friendship with John Locke. Her correspondence with him is almost entirely personal; she also entered into a brief but philosophically interesting exchange of letters with Leibniz. **See also** LOCKE, MALEBRANCHE. M.At.

Cumberland, Richard (1631–1718), English philosopher and bishop. He wrote a Latin *Treatise of the Laws of Nature* (1672), translated twice into English and once into French. Admiring Grotius, Cumberland hoped to refute Hobbes in the interests of defending Christian morality and religion. He refused to appeal to innate ideas and a priori arguments because he thought Hobbes must be attacked on his own ground. Hence he offered a reductive and naturalistic account of natural law. The one basic moral law of nature is that the pursuit of the good of all rational beings is the best path to the agent's own good. This is true because God made nature so that actions aiding others are followed by beneficial consequences to the agent, while those harmful to others harm the agent. Since the natural consequences of actions provide sanctions that, once we know them, will make us act for the good of others, we can conclude that there is a divine law by which we are obligated to act for the common good. And all the other laws of nature follow from the basic law. Cumberland refused to discuss free will, thereby suggesting a view of human action as fully determined by natural causes. If on his theory it is a blessing that God made nature (including humans) to work as it does, the religious reader must wonder if there is any role left for God concerning morality. Cumberland is generally viewed as a major forerunner of utilitarianism. **See also** **GROTIUS, HOBBES, NATURAL LAW.** J.B.S.

cum hoc ergo propter hoc. See INFORMAL FALLACY.

cumulative case argument, an argument built up from arguments that jointly establish their shared conclusion, while each argument taken individually fails to establish it. Consider a deductive cumulative case argument A composed of arguments $A_1, \ldots, A_n$. Clearly, none of the A_i or any argument built out of their premises can be sound, for if they were, no cumulative case argument would be needed. On the other hand, if the A_i are valid but not sound, then neither is an argument obtained by agglomerating the premises. Hence, deductive cumulative arguments can play only an epistemic role: having a number of valid arguments may raise my subjective confidence in the conclusion so long as the truth-values of the premises are unknown to me.

In an inductive cumulative case argument, each subargument raises the likelihood of the conclusion in such a way that, given the pairwise independence of the arguments, the subarguments jointly raise the likelihood of the conclusion to a degree higher than any of the subarguments taken individually.

Cumulative case arguments are sometimes appealed to, especially in the philosophy of religion. For instance, some authors maintain that certain groups of arguments for the existence of God, though individually inconclusive, can, when taken together, achieve their objective.

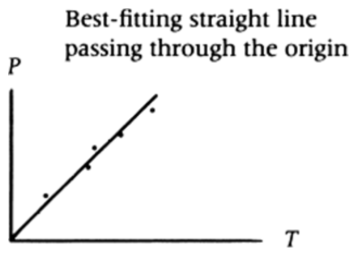
Cursus Coninbricensis. See FONSECA.

curve-fitting problem, the problem of making predictions from past observations by fitting curves to the data. Curve fitting has two steps: first, select a family of curves; then, find the best-fitting curve by some statistical criterion such as the method of least squares (e.g., choose the curve that has the least sum of squared deviations between the curve and data). The method was first proposed by Adrian Marie Legendre (1752–1833) and Carl Friedrich Gauss (1777–1855) in the early nineteenth century as a way of inferring planetary trajectories from noisy data.

More generally, curve fitting may be used to construct low-level empirical generalizations. For example, suppose that the ideal gas law, $P = nkT$, is chosen as the *form* of the law governing the dependence of the pressure P on the equilibrium temperature T of a fixed volume of gas, where n is the molecular number per unit volume and k is Boltzmann's constant (a universal constant equal to 1.3804×10^{-16} erg°C^{-1}). When the parameter nk is adjustable, the law specifies a *family* of curves – one for each numerical value of the parameter. Curve fitting may be used to determine the best-fitting member of the family, thereby effecting a measurement of the theoretical parameter, nk.



The philosophically vexing problem is how to justify the initial choice of the form of the law. On the one hand, one might choose a very large, complex family of curves, which would ensure excellent fit with *any* data set. The problem with this option is that the best-fitting curve may *overfit* the data. If too much attention is paid to the random elements of the data, then the predictively useful trends and regularities will be missed. If it looks too good to be true, it probably is. On the other hand, simpler families run a greater risk of making grossly false assumptions about the true *form* of the law. Intuitively, the solution is to choose a *simple* family of curves that maintains a reasonable degree of fit. The simplicity of a family of curves is measured by the paucity of parameters. The problem is to say how and why such a trade-off between simplicity and goodness of fit should be made.

When a theory can accommodate recalcitrant data only by the ad hoc – i.e., improperly motivated – addition of new terms and parameters, students of science have long felt that the subsequent increase in the degree of fit should not count in the theory's favor, and such additions are sometimes called ad hoc hypotheses. The best-known example of this sort of ad hoc hypothesizing is the addition of epicycles upon epicycles in the planetary astronomies of Ptolemy and Copernicus. This is an example in which a gain in fit need not compensate for the loss of simplicity.

Contemporary philosophers sometimes formulate the curve-fitting problem differently. They often assume that there is no noise in the data, and speak of the problem of choosing among different curves that fit the data *exactly*. Then the problem is to choose the simplest curve from among all those curves that pass through every data point. The problem is that there is no universally accepted way of defining the simplicity of *single* curves.

No matter how the problem is formulated, it is widely agreed that simplicity should play some role in theory choice. Rationalists have championed the curve-fitting problem as exemplifying the underdetermination of theory from data and the need to make a priori assumptions about the simplicity of nature. Those philosophers who think that we have no such a priori knowledge still need to account for the relevance of simplicity to science.

Whewell described curve fitting as the colligation of facts in the quantitative sciences, and the agreement in the measured parameters (coefficients) obtained by different colligations of facts as the consilience of inductions. Different colligations of facts (say on the same gas at different volume or for other gases) may yield good agreement among independently measured values of parameters (like the molecular density of the gas and Boltzmann's constant). By identifying different parameters found to agree, we constrain the form of the law without appealing to a priori knowledge (good news for empiricism). But the accompanying increase in unification also worsens the overall degree of fit. Thus, there is also the problem of how and why we should trade off unification with total degree of fit.

Statisticians often refer to a family of hypotheses as a *model*. A rapidly growing literature in statistics on model selection has not yet produced any universally accepted formula for trading off simplicity with degree of fit. However, there is wide agreement among statisticians that the paucity of parameters is the appropriate way of measuring simplicity.

cut, Dedekind. See DEDEKIND.

cut-elimination theorem, a theorem stating that a certain type of inference rule (including a rule that corresponds to *modus ponens*) is not needed in classical logic. The idea was anticipated by J. Herbrand; the theorem was proved by G. Gentzen and generalized by S. Kleene. Gentzen formulated a sequent calculus – i.e., a deductive system with rules for statements about derivability. It includes a rule that we here express as 'From ($C \vdash D, M$) and ($M, C \vdash D$), infer ($C \vdash D$)' or 'Given that C yields D or M, and that C plus M yields D, we may infer that C yields D'. This is called the *cut rule* because it cuts out the middle formula M. Gentzen showed that his sequent calculus is an adequate formalization of the predicate logic, and that the cut rule can be eliminated; anything provable with it can be proved without it. One important consequence of this is that, if a formula F is provable, then there is a proof of F that consists solely of subformulas of F. This fact simplifies the study of provability. Gentzen's methodology applies directly to classical logic but can be adapted to many non-classical logics, including some intuitionistic logics. It has led to some important theorems about consistency, and has illuminated the role of auxiliary assumptions in the derivation of consequences from a theory. **See also** CONSISTENCY, PROOF THEORY. D.H.

cybernetics (coined by Norbert Wiener in 1947 from Greek *kubernetes*, 'helmsman'), the study of the communication and manipulation of information in service of the control and guidance of biological, physical, or chemical energy systems. Historically, cybernetics has been intertwined with mathematical theories of information (communication) and computation. To describe the cybernetic properties of systems or processes requires ways to describe and measure information (reduce uncertainty) about events within the system and its environment. Feedback and feedforward, the basic ingredients of cybernetic processes, involve information – as what is fed forward or backward – and are basic to processes such as homeostasis in biological systems, automation in industry, and guidance systems. Of course, their most comprehensive application is to the purposive behavior (thought) of cognitively goal-directed systems such as ourselves.

Feedback occurs in closed-loop, as opposed to open-loop, systems. Actually, 'open-loop' is a misnomer (involving no loop), but it has become entrenched. The standard example of an open-loop system is that of placing a heater with constant output in a closed room and leaving it switched on. Room temperature may accidentally reach, but may also dramatically exceed, the temperature desired by the occupants. Such a heating system has no means of controlling itself to adapt to required conditions.

In contrast, the standard closed-loop system incorporates a feedback component. At the heart of cybernetics is the concept of control. A controlled process is one in which an end state that is reached depends essentially on the behavior of the controlling system and not merely on its external environment. That is, control involves partial independence for the system. A control system may be pictured as having both an inner and outer environment. The inner environment consists of the internal events that make up the system; the outer environment consists of events that causally impinge on the system, threatening disruption and loss of system integrity and stability. For a system to maintain its independence and identity in the face of fluctuations in its external environment, it must be able to detect information about those changes in the external environment. Information must pass through the interface between inner and outer environments, and the system must be able to compensate for fluctuations of the outer environment by adjusting its own inner environmental variables. Otherwise, disturbances in the outer environment will overcome the system – bringing its inner states into equilibrium with the outer states, thereby losing its identity as a distinct, independent system. This is nowhere more certain than with the homeostatic systems of the body (for temperature or blood sugar levels).

Control in the attainment of goals is accomplished by minimizing error. *Negative feedback*, or information about error, is the difference between activity a system actually performs (output) and that activity which is its goal to perform (input). The standard example of control incorporating negative feedback is the thermostatically controlled heating system. The actual room temperature (system output) carries information to the thermostat that can be compared (via goal-state comparator) to the desired temperature for the room (input) as embodied in the set-point on the thermostat; a correction can then be made to minimize the difference (error) – the furnace turns on or off.

Positive feedback tends to amplify the value of the output of a system (or of a system disturbance) by adding the value of the output to the system input quantity. Thus, the system accentuates disturbances and, if unchecked, will eventually pass the brink of instability. Suppose that as room temperature rises it causes the thermostatic set-point to rise in direct proportion to the rise in temperature. This would cause the furnace to continue to output heat (possibly with disastrous consequences). Many biological maladies have just this characteristic. For example, severe loss of blood causes inability of the heart to pump effectively, which causes loss of arterial pressure, which, in turn, causes reduced flow of blood to the heart, reducing pumping efficiency.

Cognitively goal-directed systems are also cybernetic systems. Purposive attainment of a goal by a goal-directed system must have (at least): (1) an internal representation of the goal state of the system (a detector for whether the desired state is actual); (2) a feedback loop by which information about the present state of the system can be compared with the goal state as internally represented and by means of which an error correction can be made to minimize any difference; and (3) a causal dependency of system output upon the error-correction process of condition (2) (to distinguish goal success from fortuitous goal satisfaction).

Cynics, a classical Greek philosophical school characterized by asceticism and emphasis on the sufficiency of virtue for happiness (*eudaimonia*), boldness in speech, and shamelessness in action. The Cynics were strongly influenced by Socrates and were themselves an important influence on Stoic ethics.

An ancient tradition links the Cynics to Antisthenes (c.445–c.360 B.C.), an Athenian. He fought bravely in the battle of Tanagra and claimed that he would not have been so courageous if he had been born of two Athenians instead of an Athenian and a Thracian slave. He studied with Gorgias, but later became a close companion of Socrates and was present at Socrates' death. Antisthenes was proudest of his wealth, although he had no money, because he was satisfied with what he had and he could live in whatever circumstances he found himself. Here he follows Socrates in three respects. First, Socrates himself lived with a disregard for pleasure and pain – e.g., walking barefoot in snow. Second, Socrates thinks that in every circumstance a virtuous person is better off than a nonvirtuous one; Antisthenes anticipates the Stoic development of this to the view that virtue is sufficient for happiness, because the virtuous person uses properly whatever is present. Third, both Socrates and Antisthenes stress that the soul is more important than the body, and neglect the body for the soul. Unlike the later Cynics, however, both Socrates and Antisthenes do accept pleasure when it is available. Antisthenes also does not focus exclusively on ethics; he wrote on other topics, including logic. (He supposedly told Plato that he could see a horse but not horseness, to which Plato replied that he had not acquired the means to see horseness.)

Diogenes of Sinope (c.400–c.325 B.C.) continued the emphasis on self-sufficiency and on the soul, but took the disregard for pleasure to asceticism. (According to one story, Plato called Diogenes "Socrates gone mad.") He came to Athens after being exiled from Sinope, perhaps because the coinage was defaced, either by himself or by others, under his father's direction. He took 'Deface the coinage!' as a motto, meaning that the current standards were corrupt and should be marked as corrupt by being defaced; his refusal to live by them was his defacing them. For example, he lived in a wine cask, ate whatever scraps he came across, and wrote approvingly of cannibalism and incest. One story reports that he carried a lighted lamp in broad daylight looking for an honest human, probably intending to suggest that the people he did see were so corrupted that they were no longer really people. He apparently wanted to replace the debased standards of custom with the genuine standards of nature – but nature in the sense of what was minimally required for human life, which an individual human could achieve, without society. Because of this, he was called a Cynic, from the Greek word *kuon* (dog), because he was as shameless as a dog.

Diogenes' most famous successor was Crates (fl. c.328–325 B.C.). He was a Boeotian, from Thebes, and renounced his wealth to become a Cynic. He seems to have been more pleasant than Diogenes; according to some reports, every Athenian house was open to him, and he was even regarded by them as a household god. Perhaps the most famous incident involving Crates is his marriage to Hipparchia, who took up the Cynic way of life despite her family's opposition and insisted that educating herself was preferable to working a loom. Like Diogenes, Crates emphasized that happiness is self-sufficiency, and claimed that asceticism is required for self-sufficiency; e.g., he advises us not to prefer oysters to lentils. He argues that no one is happy if happiness is measured by the balance of pleasure and pain, since in each period of our lives there is more pain than pleasure.

Cynicism continued to be active through the third century B.C. and returned to prominence in the second century A.D. after an apparent decline.

Cyrenaics, a classical Greek philosophical school that began shortly after Socrates and lasted for several centuries, noted especially for hedonism. Ancient writers trace the Cyrenaics back to Aristippus of Cyrene (fifth–fourth century B.C.), an associate of Socrates. Aristippus came to Athens because of Socrates' fame and later greatly enjoyed the luxury of court life in Sicily. (Some people ascribe the founding of the school to his grandchild Aristippus, because of an ancient report that the elder Aristippus said nothing clear about the human end.) The Cyrenaics include Aristippus's child Arete, her child Aristippus (taught by Arete), Hegesius, Anniceris, and Theodorus. The school seems to have been superseded by the Epicureans. No Cyrenaic writings survive, and the reports we do have are sketchy.

The Cyrenaics avoid mathematics and natural philosophy, preferring ethics because of its utility. (According to them, not only will studying nature not make us virtuous, it also won't make us stronger or richer.) Some reports claim that they also avoid logic and epistemology. But this is not true of all the Cyrenaics: according to other reports, they think logic and epistemology are useful, consider arguments (and also causes) as topics to be covered in ethics, and have an epistemology. Their epistemology is skeptical. We can know only how we are affected; we can know, e.g., that we are whitening, but not that whatever is causing this sensation is itself white. This differs from Protagoras's theory; unlike Protagoras the Cyrenaics draw no inferences about the things that affect us, claiming only that external things have a nature that we cannot know. But, like Protagoras, the Cyrenaics base their theory on the problem of conflicting appearances. Given their epistemology, if humans ought to aim at something that is not a way of being affected (i.e., something that is immediately perceived according to them), we can never know anything about it. Unsurprisingly, then, they claim that the end is a way of being affected; in particular, they are hedonists. The end of good actions is particular pleasures (smooth changes), and the end of bad actions is particular pains (rough changes). There is also an intermediate class, which aims at neither pleasure nor pain. Mere absence of pain is in this intermediate class, since the absence of pain may be merely a static state. Pleasure for Aristippus seems to be the sensation of pleasure, not including related psychic states. We should aim at pleasure (although not everyone does), as is clear from our naturally seeking it as children, before we consciously choose to. Happiness, which is the sum of the particular pleasures someone experiences, is choiceworthy only for the particular pleasures that constitute it, while particular pleasures are choiceworthy for themselves. Cyrenaics, then, are not concerned with maximizing total pleasure over a lifetime, but only with particular pleasures, and so they should not choose to give up particular pleasures on the chance of increasing the total.

Later Cyrenaics diverge in important respects from the original Cyrenaic hedonism, perhaps in response to the development of Epicurus's views. Hegesias claims that happiness is impossible because of the pains associated with the body, and so thinks of happiness as total pleasure minus total pain. He emphasizes that wise people act for themselves, and denies that people actually act for someone else. Anniceris, on the other hand, claims that wise people are happy even if they have few pleasures, and so seems to think of happiness as the sum of pleasures, and not as the excess of pleasures over pains. Anniceris also begins considering psychic pleasures: he insists that friends should be valued not only for their utility, but also for our feelings toward them. We should even accept losing pleasure because of a friend, even though pleasure is the end. Theodorus goes a step beyond Anniceris. He claims that the end of good actions is joy and that of bad actions is grief. (Surprisingly, he denies that friendship is reasonable, since fools have friends only for utility and wise people need no friends.) He even regards pleasure as intermediate between practical wisdom and its opposite. This seems to involve regarding happiness as the end, not particular pleasures, and may involve losing particular pleasures for long-term happiness.

H.A.I.

Czolbe, Heinrich (1819–73), German philosopher. He was born in Danzig and trained in theology and medicine. His main works are *Neue Darstellung des Sensualismus* ("New Exposition of Sensualism," 1855), *Entstehung des Selbstbewusstseins* ("Origin of Self-Consciousness," 1856), *Die Grenzen und der Ursprung der menschlichen Erkenntnis* ("The Limits and Origin of Human Knowledge," 1865), and a posthumously published study, *Grundzüge der extensionalen Erkenntnistheorie* (1875).

Czolbe proposed a sensualistic theory of knowledge: knowledge is a copy of the actual, and spatial extension is ascribed even to ideas. Space is the support of all attributes. His later work defended a non-reductive materialism. Czolbe made the rejection of the supersensuous a central principle and defended a radical "sensationalism." Despite this, he did not present a dogmatic materialism, but cast his philosophy in hypothetical form.

In his study of the origin of self-consciousness Czolbe held that dissatisfaction with the actual world generates supersensuous ideas and branded this attitude "immoral." He excluded supernatural phenomena on the basis not of physiological or scientific studies but of a "moral feeling of duty towards the natural world-order and contentment with it." The same valuation led him to postulate the eternality of terrestrial life. Nietzsche was familiar with Czolbe's works and incorporated some of his themes into his philosophy.

D

d'Ailly, Pierre (1350–1420), French Ockhamist philosopher, prelate, and writer. Educated at the Collège de Navarre, he was promoted to doctor in the Sorbonne in 1380, appointed chancellor of Paris University in 1389, consecrated bishop in 1395, and made a cardinal in 1411. He was influenced by John of Mirecourt's nominalism. He taught Gerson. At the Council of Constance (1414–18), which condemned Huss's teachings, d'Ailly upheld the superiority of the council over the pope (conciliarism). The relation of astrology to history and theology figures among his primary interests. His 1414 *Tractatus de Concordia astronomicae* predicted the 1789 French Revolution. He composed a *De anima*, a commentary on Boethius's *Consolation of Philosophy*, and another on Peter Lombard's *Sentences*. His early logical work, *Concepts and Insolubles* (c.1472), was particularly influential. In epistemology, d'Ailly contradistinguished "natural light" (indubitable knowledge) from reason (relative knowledge), and emphasized thereafter the uncertainty of experimental knowledge and the mere probability of the classical "proofs" of God's existence. His doctrine of God differentiates God's absolute power (*potentia absoluta*) from God's ordained power on earth (*potentia ordinata*). His theology anticipated fideism (*Deum esse sola fide tenetur*), his ethics the spirit of Protestantism, and his sacramentology Lutheranism. J.-L.S.

Dai Zhen (Tai Chen) (1724–77), Chinese philologist, philosopher, mathematician, and astronomer. A prominent member of the *Kaozheng* (evidential research) School, Dai attacked the Neo-Confucian dualism of *li* (pattern) and *qi* (ether), insisting that *li* is simply the orderly structure of *qi*. In terms of ethics, *li* consists of "feelings that do not err." In his *Mengzi Ziyi Shuzheng* ("Meanings of Terms in the *Mencius* Explained and Attested"), Dai argues for the need to move from mere *yijian* (opinions) to *buyi zhili* (undeviating standards) by applying the Confucian golden rule not as a formal principle determining right action but as a winnowing procedure that culls out improper desires and allows only proper ones to inform one's actions. Beginning with *ziran* (natural) desires, one tests their universalizability with the golden rule, thereby identifying those that accord with what is *biran* (necessary). One spontaneously *ke* (approves of) the "necessary," and Dai claims this is what Mencius describes as the "joy" of moral action. **See also** MENCIUS. P.J.I.

d'Alembert, Jean Le Rond (1717–83), French mathematician, philosopher, and Encyclopedist. According to Grimm, d'Alembert was the prime luminary of the philosophic party. An abandoned, illegitimate child, he nonetheless received an outstanding education at the Jansenist Collège des Quatre-Nations in Paris. He read law for a while, tried medicine, and settled on mathematics. In 1743, he published an acclaimed *Treatise of Dynamics*. Later, he joined the Paris Academy of Sciences and contributed decisive works on mathematics and physics. In 1754, he was elected to the French Academy, of which he later became permanent secretary. In association with Diderot, he launched the *Encyclopedia*, for which he wrote the epoch-making *Discours préliminaire* (1751) and numerous entries on science. Unwilling to compromise with the censorship, he resigned as coeditor in 1758.

In the *Discours préliminaire*, d'Alembert specified the divisions of the philosophical discourse on man: pneumatology, logic, and ethics. Contrary to Christian philosophies, he limited pneumatology to the investigation of the human soul. Prefiguring positivism, his *Essay on the Elements of Philosophy* (1759) defines philosophy as a comparative examination of physical phenomena. Influenced by Bacon, Locke, and Newton, d'Alembert's epistemology associates Cartesian psychology with the sensory origin of ideas. Though assuming the universe to be rationally ordered, he discarded metaphysical questions as inconclusive. The substance, or the essence, of soul and matter is unknowable. Agnosticism ineluctably arises from his empirically based naturalism. D'Alembert is prominently featured in *D'Alembert's Dream* (1769), Diderot's dialogical apology for materialism.

Damascene, John. See JOHN OF DAMASCUS.

Damascius (c.462–c.550), Greek Neoplatonist philosopher, last head of the Athenian Academy before its closure by Justinian in A.D. 529. Born probably in Damascus, he studied first in Alexandria, and then moved to Athens shortly before Proclus's death in 485. He returned to Alexandria, where he attended the lectures of Ammonius, but came back again to Athens in around 515, to assume the headship of the Academy. After the closure, he retired briefly with some other philosophers, including Simplicius, to Persia, but left after about a year, probably for Syria, where he died.

He composed many works, including a life of his master Isidorus, which survives in truncated form; commentaries on Aristotle's *Categories*, *On the Heavens*, and *Meteorologics* I (all lost); commentaries on Plato's *Alcibiades*, *Phaedo*, *Philebus*, and *Parmenides*, which survive; and a surviving treatise *On First Principles*. His philosophical system is a further elaboration of the scholastic Neoplatonism of Proclus, exhibiting a great proliferation of metaphysical entities.

See also NEOPLATONISM. J.M.D.

Dancy, Jonathan (b.1946), British philosopher working in moral theory, philosophy of action, and epistemology. His views in these fields are united by a unique picture of the nature of reasons and their relation to belief and action. In moral theory Dancy is best known for developing moral particularism, a realist view according to which ethics would be better off without principles. This view stems from a holism concerning the situation-dependent value of contributory features (including reasons for action), which has also been applied to aesthetics, language, science, and other fields typically thought to be governed by principles, laws, or rules. In philosophy of action he has argued for an anti-psychologistic theory of "motivating reasons" on which the reasons for which we act are ontologically on a par with the normative reasons that make actions right (of which he has defended an anti-naturalist realist account). More specifically, Dancy argues for the anti-Humean view that such reasons are not belief-desire states but rather things that we believe (supposed or actual matters of fact). A corollary of this view is that the explanation of action by appeal to motivating reasons is non-factive and therefore also non-causal.

Dancy's epistemology, like his early Berkeley scholarship, is partly motivated by a search for a direct realism capable of resisting arguments from illusion. His work in philosophy of perception forms a bridge between purely epistemic inquiries and a moral epistemology (responding to Ross and Prichard) that in turn links the theory of reasons to intuitionist moral particularism. In recent years Dancy has also sought to establish an Aristotelian account of practical reasoning on which deliberation may conclude in action, as opposed to belief or mere intention.

See also PARTICULARISM, REASONS FOR ACTION. C.Sa.

Dante. See ITALIAN PHILOSOPHY.

Danto, Arthur C(oleman) (1924–2013), American philosopher of art and art history who also contributed to the philosophies of history, action, knowledge, science, and metaphilosophy. Among his influential studies in the history of philosophy are books on Nietzsche, Sartre, and Indian thought.

Danto arrives at his philosophy of art through his "method of indiscernibles," which has greatly influenced contemporary philosophical aesthetics. According to his metaphilosophy, genuine philosophical questions arise when there is a theoretical need to differentiate two things that are perceptually indiscernible – such as prudential actions versus moral actions (Kant), causal chains versus constant conjunctions (Hume), and perfect dreams versus reality (Descartes). Applying the method to the philosophy of art, Danto asks what distinguishes an artwork, such as Warhol's *Brillo Box*, from its perceptually indiscernible, real-world counterparts, such as Brillo boxes by Proctor & Gamble. His answer – his partial definition of art – is that x is a work of art only if (1) x is about something and (2) x embodies its meaning (i.e., discovers a mode of presentation intended to be appropriate to whatever subject x is about). These two necessary conditions, Danto claims, enable us to distinguish between artworks and real things – between Warhol's *Brillo Box* and Proctor & Gamble's.

However, critics have pointed out that these conditions fail, since real Brillo boxes are about something (Brillo) concerning which they convey meanings through their mode of presentation (namely that Brillo is clean, fresh, and dynamic). Moreover, this is not an isolated example. Danto's theory of art confronts systematic difficulties in differentiating real cultural artifacts, such as industrial packages, from artworks proper.

In addition to his philosophy of art, Danto proposes a philosophy of art history. Like Hegel, Danto maintains that art history – as a developmental, progressive process – has ended. Danto believes that modern art has been primarily reflexive (i.e., about itself); it has attempted to use its own forms and strategies to disclose the essential nature of art. Cubism and abstract expressionism, e.g., exhibit saliently the two-dimensional nature of painting. With each experiment, modern art has gotten closer to disclosing its own essence. But, Danto argues, with works such as Warhol's *Brillo Box*, artists have taken the philosophical project of self-definition as far as they can, since once an artist like Warhol has *shown* that artworks can be perceptually indiscernible from "real things" and, therefore, can *look like anything*, there is nothing further that the artist *qua* artist can *show* through the medium of appearances about the nature of art. The task of defining art must be reassigned to philosophers to be treated discursively, and art history – as the developmental, progressive narrative of self-definition – ends.

Since that turn of events was putatively precipitated by Warhol in the 1960s, Danto calls the present period of art making "post-historical." As an art critic for *The Nation*, he chronicled its vicissitudes for a decade and a half. Some dissenters, nevertheless, have been unhappy with Danto's claim that art history has ended because, they maintain, he has failed to demonstrate that the only prospects for a developmental, progressive history of art reside in the project of the self-definition of art.

See also AESTHETICS. N.C.

dao **(*tao*)** (Chinese, 'path', 'way', 'account'). From the sense of a literal path, road, or way, the term comes to mean a way of doing something (e.g., living one's life or organizing society), especially the way advocated by a particular individual or school of thought ("the way of the Master," "the way of the Mohists," etc.). Frequently, it refers to *the* way of doing something, the right way (e.g., "The Way has not been put into practice for a long time"). *Dao* also came to refer to the linguistic account that embodies or describes a way. Finally, in some texts the *dao* is a metaphysical entity. For example, in Neo-Confucianism, *dao* is identified with *li* (principle). In some contexts it is difficult to tell what sense is intended.

See also LI[1], NEO-CONFUCIANISM. B.W.V.N.

Daodejing **(*Tao Te Ching*).** See LAOZI.

Daoism (Taoism), a Chinese philosophy identified with the *Daojia* (School of the Way), represented by Zhuangzi and Laozi. The term may also refer to the Huang-Lao School; Neo-Daoists, such as Wang Bi and Guo Xiang; and *Daojiao*, a diverse religious movement. Only the *Daojia* is discussed here.

The school derives its name from the word *dao* (Way), a term used by Chinese thinkers of almost every persuasion. Daoists were the first to use the term to describe the comprehensive structure and dynamic of the cosmos. Daoists believe that (1) there is a way the world should be, a way that, in some deep sense, it is; (2) human beings can understand this and need to have and follow such knowledge if they and the world are to exist in harmony; and (3) the world was once in such a state. Most early Chinese thinkers shared similar beliefs, but Daoists are distinct in claiming that the Way is not codifiable, indeed is ineffable. Daoists thus are metaphysical and ethical realists, but epistemological skeptics of an unusual sort, being language skeptics. Daoists further deny that one can strive successfully to attain the Way; Daoist self-cultivation is a process not of accumulation but of paring away. One must unweave the social fabric, forsake one's cultural conditioning, and abandon rational thought, to be led instead by one's *ziran* (spontaneous) inclinations. With a *xu* (tenuous) mind, one then will perceive the *li* (pattern) of the cosmos and live by *wuwei* (non-action).

Though sharing a strong family resemblance, the Daoisms of Laozi and Zhuangzi are distinct. Laozi advocates a primitive utopianism in which people enjoy the simple life of small agrarian communities, indifferent to what is happening in the neighboring village. Having abandoned cultural achievements such as writing, they keep accounts by knotting cords. Laozi blames human "cleverness," which imposes the "human" on the "Heavenly," for most of what is bad in the world. For him, a notion like beauty gives rise to its opposite and only serves to increase anxiety and dissatisfaction; extolling a virtue, such as benevolence, only encourages people to affect it hypocritically. Laozi advocates "turning back" to the time when intellect was young and still obedient to intuition and instinct. To accomplish this, the Daoist sage must rule and enforce this view upon the clever, if they should "dare to act."

Zhuangzi emphasizes changing oneself more than changing society. He too is a kind of anti-rationalist and sees wisdom as a "knowing how" rather than a "knowing that." He invokes a repertoire of skillful individuals as exemplars of the Way. Such individuals engage the world through a knack that eludes definitive description and display all the Daoist virtues. Their minds are *xu* (empty) of preconceptions, and so they perceive the *li* (pattern) in each situation. They respond spontaneously and so are *ziran;* they don't force things and so practice *wuwei*. In accord with the *dao*, they lead a frictionless existence; they "walk without touching the ground."

See also DAO, NEO-DAOISM. P.J.I.

daotong **(*tao-t'ung*)** (Chinese, 'the orthodox line of transmission of the Way'). According to Zhu Xi (1130–1200), the first to use this term, the line of transmission can be traced back to ancient sage-emperors, Confucius, and Mencius. The line was broken after Mencius and was revived only by the Cheng brothers in the Song dynasty. The interesting feature is that the line has excluded important Confucian scholars such as Xunzi (fl. 298–238 B.C.) and Dong Zhongshu (c.179–c.104 B.C.). The idea of *daotong* can be traced back to Han Yu (768–824) and Mencius. **See also** CONFUCIANISM, CONFUCIUS, DONG ZHONGSHU, HAN YU, MENCIUS, NEO-CONFUCIANISM, XUNZI, ZHU XI. S.-h.L.

daoxin, renxin **(*tao-hsin, jen-hsin*),** Chinese terms used by Neo-Confucian philosophers to contrast the mind according to the Way (*daoxin*) and the mind according to man's artificial, selfish desires (*renxin*). When one responds spontaneously without making discrimination, one is acting according to the Way. One is naturally happy, sad, angry, and joyful as circumstances require. But when one's self is alienated from the Way, one works only from self-interest, and the emotions and desires are excessive and deviate from the Mean. In the Confucian tradition sages and worthies take Heaven as their model, while common people are urged to take *junzi* (superior men) as their model. **See also** NEO-CONFUCIANISM, TIANLI, RENYU. S.-h.L.

Darwall, Stephen (b.1946), American philosopher best known for his work in moral philosophy. His primary philosophical concern has been the nature of moral obligation and its relation to human agency. His approach is broadly Kantian, in that it seeks to show that moral motivation is autonomous motivation. His earliest major work, *Impartial Reason* (1983), attempts to vindicate one version of this "internalist" conception by appeal to a constructive procedure reminiscent of John Rawls's Original Position. In his second book, *The British Moralists and the Internal 'Ought': 1640–1740* (1995), Darwall traces the evolution of Kantian internalism in the early modern period, explaining the significance of thinkers like Cudworth, Shaftesbury, and Butler to the development of Kant's position. Darwall's most original contribution, however, is his book, *The Second-Person Standpoint: Respect, Morality, and Accountability* (2006). There he draws on the thought of Pufendorf, Smith, Fichte, and Peter Strawson to show that moral obligation is an essentially interpersonal concept, one that presupposes a background of authority and accountability relations between persons. This understanding of moral obligation, Darwall maintains, has implications for our understanding of a host of associated concepts having to do with value, agency, and morality.

After receiving his B.A. from Yale University in 1968 and his Ph.D. from the University of Pittsburgh in 1972, he taught at the University of North Carolina at Chapel Hill. In 1984 he moved to the University of Michigan, where he remained for more than two decades. During that time he and his colleagues David Velleman, Peter Railton, and Alan Gibbard made that university one of the most vibrant centers of moral philosophy in the world. In 2008, Darwall left Michigan and assumed his current position as Andrew Downey Orrick Professor at Yale University.

Darwin, Charles. See DARWINISM.

Darwinism, the view that biological species evolve primarily by means of chance variation and natural selection. Although several important scientists prior to Charles Darwin (1809–82) had suggested that species evolve and had provided mechanisms for that evolution, Darwin was the first to set out his mechanism in sufficient detail and provide adequate empirical grounding. Even though Darwin preferred to talk about descent with modification, the term that rapidly came to characterize his theory was *evolution*. According to Darwin, organisms vary with respect to their characteristics. In a litter of puppies, some will be bigger, some will have longer hair, some will be more resistant to disease, etc. Darwin termed these variations chance, not because he thought that they were in any sense "uncaused," but to reject any general correlation between the variations that an organism might need and those it gets, as Lamarck had proposed. Instead, successive generations of organisms become adapted to their environments in a more roundabout way. Variations occur in all directions. The organisms that happen to possess the characteristics necessary to survive and reproduce proliferate. Those that do not either die or leave fewer offspring.

Before Darwin, an adaptation was any trait that fits an organism to its environment. After Darwin, the term came to be limited to just those useful traits that arose through natural selection. For example, the sutures in the skulls of mammals make parturition easier, but they are not adaptations in an evolutionary sense because they arose in ancestors that did not give birth to live young, as is indicated by these same sutures appearing in the skulls of egg-laying birds. Because organisms are integrated systems, Darwin thought that adaptations had to arise through the accumulation of numerous, small variations. As a result, evolution is gradual. Darwin himself was unsure about how progressive biological evolution is. Organisms certainly become better adapted to their environments through successive generations, but as fast as organisms adapt to their environments, their environments are likely to change. Thus, Darwinian evolution may be goal-directed, but different species pursue different goals, and these goals keep changing.

Because heredity was so important to his theory of evolution, Darwin supplemented it with a theory of heredity – *pangenesis*. According to this theory, the cells throughout the body of an organism produce numerous tiny gemmules that find their way to the reproductive organs of the organism to be transmitted in reproduction. An offspring receives variable numbers of gemmules from each of its parents for each of its characteristics. For instance, the male parent might contribute 214 gemmules for length of hair to one offspring, 121 to another, etc., while the female parent might contribute 54 gemmules for length of hair to the first offspring and 89 to the second. As a result, characters tend to blend. Darwin even thought that gemmules themselves might merge, but he did not think that the merging of gemmules was an important factor in the blending of characters. Numerous objections were raised to Darwin's theory in his day, and one of the most telling stemmed from his adopting a blending theory of inheritance. As fast as natural selection biases evolution in a particular direction, blending inheritance neutralizes its effects. Darwin's opponents argued that each species had its own range of variation. Natural selection might bias the organisms belonging to a species in a particular direction, but as a species approached its limits of variation, additional change would become more difficult. Some special mechanism was needed to leap over the deep, though possibly narrow, chasms that separate species.

Because a belief in biological evolution became widespread within a decade or so after the publication of Darwin's *Origin of Species* in 1859, the tendency is to think that it was Darwin's view of evolution that became popular. Nothing could be further from the truth. Darwin's contemporaries found his theory too materialistic and haphazard because no supernatural or teleological force influenced evolutionary development. Darwin's contemporaries were willing to accept evolution, but not the sort advocated by Darwin. Although Darwin viewed the evolution of species on the model of individual development, he did not think that it was directed by some internal force or induced in a Lamarckian fashion by the environment. Most Darwinians adopted just such a position. They also argued that species arise in the space of a single generation so that the boundaries between species remained as discrete as the creationists had maintained. Ideal morphologists even eliminated any genuine temporal dimension to evolution. Instead they viewed the evolution of species in the same atemporal way that mathematicians view the transformation of an ellipse into a circle. The revolution that Darwin instigated was in most respects non-Darwinian. By the turn of the century, Darwinism had gone into a decided eclipse.

Darwin himself remained fairly open with respect to the mechanisms of evolution. For example, he was willing to accept a minor role for Lamarckian forms of inheritance, and he acknowledged that on occasion a new species might arise quite rapidly on the model of the Ancon sheep. Several of his followers were less flexible, rejecting all forms of Lamarckian inheritance and insisting that evolutionary change is always gradual. Eventually Darwinism became identified with the views of these neo-Darwinians. Thus, when Mendelian genetics burst on the scene at the turn of the century, opponents of Darwinism interpreted this new particulate theory of inheritance as being incompatible with Darwin's blending theory. The difference between Darwin's theory of pangenesis and Mendelian genetics, however, did not concern the existence of hereditary particles. Gemmules were as particulate as genes. The difference lay in numbers. According to early Mendelians, each character is controlled by a single pair of genes. Instead of receiving a variable number of gemmules from each parent for each character, each offspring gets a single gene from each parent, and these genes do not in any sense blend with each other. Blue eyes remain as blue as ever from generation to generation, even when the gene for blue eyes resides opposite the gene for brown eyes.

As the nature of heredity was gradually worked out, biologists began to realize that a Darwinian view of evolution could be combined with Mendelian genetics. Initially, the founders of this later stage in the development of neo-Darwinism exhibited considerable variation in their beliefs about the evolutionary process, but as they strove to produce a single, synthetic theory, they tended to become more Darwinian than Darwin had been. Although they acknowledged that other factors, such as the effects of small numbers, might influence evolution, they emphasized that natural selection is the sole directive force in evolution. It alone could explain the complex adaptations exhibited by organisms. New species might arise through the isolation of a few founder organisms, but from a populational perspective, evolution was still gradual. New species do not arise in the space of a single generation by means of "hopeful monsters" or any other developmental means. Nor was evolution in any sense directional or progressive. Certain lineages might become more complex for a while, but at this same time, others would become simpler. Because biological evolution is so opportunistic, the tree of life is highly irregular. But the united front presented by the neo-Darwinians was in part an illusion. Differences of opinion persisted, for instance over how heterogeneous species should be.

No sooner did neo-Darwinism become the dominant view among evolutionary biologists than voices of dissent were raised. Currently, almost every aspect of the neo-Darwinian paradigm is being challenged. No one proposes to reject naturalism, but those who view themselves as opponents of neo-Darwinism urge more important roles for factors treated as only minor by the neo-Darwinians. For example, neo-Darwinians view selection as being extremely sharp-sighted. Any inferior organism, no matter how slightly inferior, is sure to be eliminated. Nearly all variations are deleterious. Currently evolutionists, even those who consider themselves Darwinians, acknowledge that a high percentage of changes at the molecular level may be neutral with respect to survival or reproduction. On current estimates, over 95 percent of an organism's genes may have no function at all. Disagreement also exists about the level of organization at which selection can operate. Some evolutionary biologists insist that selection occurs primarily at the level of single genes, while others think that it can have effects at higher levels of organization, certainly at the organismic level, possibly at the level of entire species. Some biologists emphasize the effects of developmental constraints on the evolutionary process, while others have discovered unexpected mechanisms such as molecular drive. How much of this conceptual variation will become incorporated into Darwinism remains to be seen.

Davidson, Donald (1917–2003), American metaphysician and philosopher of mind and language. His views on the relationship between our conceptions of ourselves as persons and as complex physical objects have had an enormous impact on contemporary philosophy. Davidson regards the mind-body problem as the problem of the relation between mental and physical events; his discussions of explanation assume that the entities explained are events; causation is a relation between events; and action is a species of events, so that events are the very subject matter of action theory. His central claim concerning events is that they are concrete particulars – unrepeatable entities located in space and time. He does not take for granted that events exist, but argues for their existence and for specific claims as to their nature.

In "The Individuation of Events" (in *Essays on Actions and Events*, 1980), Davidson argues that a satisfactory theory of action must recognize that we talk of the same action under different descriptions. We must therefore assume the existence of actions. His strongest argument for the existence of events derives from his most original contribution to metaphysics, the semantic method of truth (in *Essays on Actions and Events* and *Essays on Truth and Interpretation*, 1984). The argument is based on a distinctive trait of the English language (one not obviously shared by signal systems in lower animals), namely its productivity of combinations. We learn modes of composition as well as words and are thus prepared to produce and respond to complex expressions never before encountered. Davidson argues, from such considerations, that our very understanding of English requires assuming the existence of events.

To understand Davidson's rather complicated views about the relationships between mind and body, consider the following claims:

(1) The mental and the physical are distinct.
(2) The mental and the physical causally interact.
(3) The physical is causally closed.

Claim (1) says that no mental event is a physical event; (2), that some mental events cause physical events and vice versa; and (3), that all the causes of physical events are physical events. If mental events are distinct from physical events and sometimes cause them, then the physical is not causally closed. The dilemma posed by the plausibility of each of these claims and by their apparent incompatibility just is the traditional mind-body problem.

Davidson's resolution consists of three theses:

(4) There are no strict psychological or psychophysical laws; in fact, all strict laws are expressible in purely physical vocabulary.
(5) Mental events causally interact with physical events.
(6) Event c causes event e only if some strict causal law subsumes c and e.

It is commonly held that a property expressed by M is reducible to a property expressed by P (where M and P are not logically connected) only if some exceptionless law links them. So, given (4), mental and physical properties are distinct. (6) says that c causes e only if there are singular descriptions, D of c and D' of e, and a "strict" causal law, L, such that L and 'D occurred' entail 'D caused D''. (6) and the second part of (4) entail that physical events have only physical causes and that all event causation is physically grounded.

Given the parallel between (1)–(3) and (4)–(6), it may seem that the latter, too, are incompatible. But Davidson shows that they all can be true if (and only if) mental events are identical to physical events. Let us say that an event e is a physical event if and only if e satisfies a basic physical predicate (i.e., a physical predicate appearing in a "strict" law). Since only physical predicates (or predicates expressing properties reducible to basic physical properties) appear in "strict" laws, every event that enters into causal relations satisfies a basic physical predicate. So those mental events that enter into causal relations are also physical events. Still, the anomalous monist is committed only to a partial endorsement of (1). The mental and physical are distinct insofar as they are not linked by strict law – but they are not distinct insofar as mental events are in fact physical events.

E.L.

***Daxue* (*Ta-hsüeh*),** a part of the Chinese Confucian classic *Book of Rites* whose title is standardly translated as *Great Learning*. Zhu Xi significantly amended the text (composed in the third or second century B.C.) and elevated it to the status of an independent classic as one of the Four Books. He regarded it as a quotation from Confucius and a commentary by Confucius's disciple Zengzi, but neither his emendations nor his interpretation of the text are beyond dispute.

The *Daxue* instructs a ruler in how to bring order to his state by self-cultivation. Much discussion of the text revolves around the phrase *gewu*, which describes the first step in self-cultivation but is left undefined. The *Daxue* claims that one's virtuousness or viciousness is necessarily evident to others, and that virtue manifests itself first in one's familial relationships, which then serve as an exemplar of order in both families and the state.

See also CONFUCIANISM. B.W.V.N.

***de* (*te*),** in Chinese philosophy, and using a literal translation, 'virtue' or (sometimes) 'excellence'. The term also has been translated as 'power' or 'potency', as it occurs in the early Daoist texts. The term can be traced to the *Book of Documents*, one of six Confucian classics and the earliest written historical record of government affairs in China. *De*, especially in the Confucian tradition, is (morally) good character or the special combination of good character traits which always hits the Mean. *Ren* (benevolence), *yi* (righteousness), *li* (ritual propriety), and *zhi* (wisdom) are four Confucian cardinal virtues or, roughly equivalently, *de*. Confucian teaching emphasizes the central importance of cultivating *de* in a life worth living. For the Confucians, a life worth living is one that manifests the highest *de*. In the early Daoist texts, people with *de* are those who transcend all the distinctions (fortunes or misfortunes) and attract others with their inner power or *de*. According to early Daoists, to cultivate such a power is essential for achieving a life worth living. **See also** CONFUCIANISM, DAOISM, LI^2, YI. X.Y.

death, loss of life, either absolutely or in a qualified manner or degree; also, the metaphysical condition resulting therefrom. Different conceptions of life involve different accounts of death's nature and significance. Materialists such as Democritus and Hobbes see death as exhaustion of the body's functionality: the machine stops. Anti-materialists, from Pythagoras on, view that functionality as translatable to some alternative plane of action (another "body" or "world"). Some believe, with Williams, that it is death that makes life meaningful, rescuing mortals from a tedious immortality; others think death deprives life of meaning by making any possible human achievements impermanent. Some see the fear of death as the primary problem. Lucretius argues that there is "nothing to be feared" in death, as posthumous nonexistence can be no more lamentable than the time one did not exist before birth. Others regard an attitude of fear as part of the definition. Samuel Johnson, hearing of Hume's equanimity in dying, insisted that Hume must not have had death clearly in view, as no one could conceive of extinction without fearing it. Existentialist thinkers, influenced by Heidegger, have regarded an individual's "being toward death" as an index of personal integrity (or "authenticity"). In medical ethics, important practical decisions (e.g., regarding organ transplants or life support) may be affected by how death is defined. Since functions such as breathing and blood circulation can often be sustained mechanically, definitions in terms of "brain death" may permit decisions that more holistic definitions might forbid. **See also** PERSONAL IDENTITY, SOUL, SURVIVAL. E.J.

de Beauvoir, Simone. See EXISTENTIALISM.

decidability, as a property of sets, the existence of an effective procedure (a "decision procedure") which, when applied to any object, determines whether or not the object belongs to the set. A theory or logic is decidable if and only if the set of its theorems is. Decidability is proved by describing a decision procedure and showing that it works. The truth table method, e.g., establishes that classical propositional logic is decidable. To prove that something is not decidable requires a more precise characterization of the notion of effective procedure. Using one such characterization (for which there is ample evidence), Church proved that classical predicate logic is not decidable. **See also** CHURCH'S THESIS, TRUTH TABLE, TURING MACHINE. S.T.K.

decidable. See DECIDABILITY.

decision theory, the theory of rational decision, often called "rational choice theory" in political science and other social sciences. The basic idea (probably Pascal's) was published at the end of Arnaud's *Port-Royal Logic* (1662): "To judge what one must do to obtain a good or avoid an evil one must consider not only the good and the evil in itself but also the probability of its happening or not happening, and view geometrically the proportion that all these things have together."

Where goods and evils are monetary, Daniel Bernoulli (1738) spelled the idea out in terms of expected *utilities* as figures of merit for actions, holding that "in the absence of the unusual, the utility resulting from a fixed small increase in wealth will be inversely proportional to the quantity of goods previously possessed." This was meant to solve the *St. Petersburg paradox:*

> Peter tosses a coin . . . until it should land "heads" [on toss *n*]. . . . He agrees to give Paul one ducat if he gets "heads" on the very first throw [and] with each additional throw the number of ducats he must pay is doubled. . . . Although the standard calculation shows that the value of Paul's expectation [*of gain*] is infinitely great [i.e., the sum of all possible gains × probabilities, $2^n/2 \times ½^n$], it has . . . to be admitted that any fairly reasonable man would sell his chance, with great pleasure, for twenty ducats.

In this case Paul's expectation of utility is indeed finite on Bernoulli's assumption of inverse proportionality; but as Karl Menger observed (1934), Bernoulli's solution fails if payoffs are so large that *utilities* are inversely proportional to probabilities; then only boundedness of utility scales resolves the paradox.

Bernoulli's idea of diminishing marginal utility of wealth survived in the neoclassical texts of W. S. Jevons (1871), Alfred Marshall (1890), and A. C. Pigou (1920), where personal utility judgment was understood to cause preference. But in the 1930s, operationalistic arguments of John Hicks and R. G. D. Allen persuaded economists that, on the contrary, (1) utility is no cause but a description, in which (2) the numbers indicate preference order but not intensity. In their *Theory of Games and Economic Behavior* (1946), John von Neumann and Oskar Morgenstern undid (2) by pushing (1) further: ordinal preferences among *risky* prospects were now seen to be describable on "interval" scales of subjective utility (like the Fahrenheit and Celsius scales for temperature), so that once utilities, e.g., 0 and 1, are assigned to any prospect and any preferred one, utilities of all prospects are determined by overall preferences among gambles, i.e. probability distributions over prospects. Thus, the utility midpoint between two prospects is marked by the distribution assigning probability ½ to each.

In fact, Ramsey had done that and more in a little-noticed essay ("Truth and Probability," 1931) teasing subjective probabilities as well as utilities out of ordinal preferences among gambles. In a form independently invented by L. J. Savage (*Foundations of Statistics*, 1954), this approach is now widely accepted as a basis for rational *decision analysis*. The 1968 book of that title by Howard Raiffa became a theoretical centerpiece of M.B.A. curricula, whose graduates diffused it through industry, government, and the military in a simplified format for defensible decision making, namely "cost-benefit analyses," substituting expected numbers of dollars, deaths, etc., for preference-based expected utilities.

Social choice and group decision form the native ground of interpersonal comparison of personal utilities. Thus, John C. Harsanyi (1955) proved that if (1) individual and social preferences all satisfy the von Neumann-Morgenstern axioms, and (2) society is indifferent between two prospects whenever all individuals are, and (3) society prefers one prospect to another whenever someone does and nobody has the opposite preference, then social utilities are expressible as sums of individual utilities on interval scales obtained by stretching or compressing the individual scales by amounts determined by the social preferences. Arguably, the theorem shows how to derive interpersonal comparisons of individual preference intensities from social preference orderings that are thought to treat individual preferences on a par. Somewhat earlier, Kenneth Arrow had written that "interpersonal comparison of utilities has no meaning and, in fact, there is no meaning relevant to welfare economics in the measurability of individual utility" (*Social Choice and Individual Values*, 1951) – a position later abandoned (P. Laslett and W. G. Runciman, eds., *Philosophy, Politics and Society*, 1967). Arrow's "impossibility theorem" is illustrated by cyclic preferences (observed by Condorcet in 1785) among candidates A, B, C of voters 1, 2, 3, who rank them ABC, BCA, CAB, respectively, in decreasing order of preference, so that majority rule yields intransitive preferences for the group of three, of whom two (1, 3) prefer A to B and two (1, 2) prefer B to C but two (2, 3) prefer C to A. In general, the theorem denies the existence of technically democratic schemes for forming social preferences from citizens' preferences. A clause tendentiously called "independence of irrelevant alternatives" in the definition of 'democratic' rules out appeal to preferences among noncandidates as a way to form social preferences among candidates, thus ruling out the preferences among gambles used in Harsanyi's theorem. (See John Broome, *Weighing Goods*, 1991, for further information and references.)

Savage derived the agent's probabilities for states as well as utilities for consequences from preferences among abstract acts, represented by deterministic assignments of consequences to states. An act's place in the preference ordering is then reflected by its *expected utility*, a probability-weighted average of the utilities of its consequences in the various states. Savage's states and consequences formed distinct sets, with every assignment of consequences to states constituting an act. While Ramsey had also taken acts to be functions from states to consequences, he took consequences to be propositions (sets of states), and assigned utilities to states, not consequences. A further step in that direction represents acts, too, by propositions (see Ethan Bolker, *Functions Resembling Quotients of Measures*, University Microfilms, 1965; and Richard Jeffrey, *The Logic of Decision*, 1965, 1990). Bolker's representation theorem states conditions under which preferences between truth of propositions determine probabilities and utilities nearly enough to make the position of a proposition in one's preference ranking reflect its "desirability," i.e. one's expectation of utility conditionally on it.

Alongside such basic properties as transitivity and connexity, a workhorse among Savage's assumptions was the "sure-thing principle":

> Preferences among acts having the same consequences in certain states are unaffected by arbitrary changes in those consequences.

This implies that agents see states as probabilistically independent of acts, and therefore implies that an act cannot be preferred to one that *dominates* it in the sense that the dominant act's consequences in each state have utilities at least as great as the other's. Unlike the sure-thing principle, the principle 'Choose so as to maximize CEU (conditional expectation of utility)' rationalizes action aiming to enhance probabilities of preferred states of nature, as in quitting cigarettes to increase life expectancy. But as Nozick pointed out in 1969, there are problems in which choice worthiness goes by dominance rather than CEU, as when the smoker (like R. A. Fisher in 1959) believes that the statistical association between smoking and lung cancer is due to a genetic allele, possessors of which are more likely than others to smoke and to contract lung cancer, although among them smokers are not especially likely to contract lung cancer. In such ("Newcomb") problems, choices are ineffectual signs of conditions that agents would promote or prevent if they could. *Causal decision theories* modify the CEU formula to obtain figures of merit distinguishing causal efficacy from evidentiary significance – e.g., replacing conditional probabilities by probabilities of counterfactual conditionals; or forming a weighted average of CEUs under all hypotheses about causes, with agents' unconditional probabilities of hypotheses as weights; etc.

Mathematical statisticians leery of subjective probability have cultivated Abraham Wald's *Theory of Statistical Decision Functions* (1950), treating statistical estimation, experimental design, and hypothesis testing as zero-sum "games against nature." For an account of the opposite assimilation, of game theory to probabilistic decision theory, see Skyrms, *Dynamics of Rational Deliberation* (1990).

The "preference logics" of Sören Halldén, *The Logic of 'Better'* (1957), and G. H. von Wright, *The Logic of Preference* (1963), sidestep probability. Thus, Halldén holds that when truth of p is preferred to truth of q, falsity of q must be preferred to falsity of p, and von Wright (with Aristotle) holds that "this is more choice worthy than that if this is choice worthy without that, but that is not choice worthy without this" (*Topics* III, 118a). Both principles fail in the absence of special probabilistic assumptions, e.g. equiprobability of p with q.

Received wisdom counts decision theory clearly false as a description of human behavior, seeing its proper status as normative. But some, notably Davidson, see the theory as constitutive of the very concept of preference, so that, e.g., preferences can no more be intransitive than propositions can be at once true and false.

deconstruction, a demonstration of the incompleteness or incoherence of a philosophical position using concepts and principles of argument whose meaning and use is legitimated only by that philosophical position. A deconstruction is thus a kind of internal conceptual critique in which the critic implicitly and provisionally adheres to the position criticized. The early work of Derrida is the source of the term and provides paradigm cases of its referent.

That deconstruction remains within the position being discussed follows from a fundamental deconstructive argument about the nature of language and thought. Derrida's earliest deconstructions argue against the possibility of an interior "language" of thought and intention such that the senses and referents of terms are determined by their very nature. Such terms are "meanings," or *logoi*. Derrida calls accounts that presuppose such magical thought-terms "logocentric." He claims, following Heidegger, that the conception of such *logoi* is basic to the concepts of Western metaphysics, and that Western metaphysics is fundamental to our cultural practices and languages. Thus there is no "ordinary language" uncontaminated by philosophy. *Logoi* ground all our accounts of intention, meaning, truth, and logical connection. Versions of *logoi* in the history of philosophy range from Plato's Forms through the self-interpreting ideas of the empiricists to Husserl's intentional entities.

Thus Derrida's fullest deconstructions are of texts that give explicit accounts of *logoi*, especially his discussion of Husserl in *Speech and Phenomena*. There, Derrida argues that meanings that are fully present to consciousness are in principle impossible. The idea of a meaning is the idea of a repeatable ideality. But "repeatability" is not a feature that can be present. So meanings, as such, cannot be fully before the mind. Self-interpreting *logoi* are an incoherent supposition.

Without *logoi*, thought and intention are merely wordlike and have no intrinsic connection to a sense or a referent. Thus "meaning" rests on connections of all kinds among pieces of language and among our linguistic interactions with the world. Without *logoi*, no special class of connections is specifically "logical." Roughly speaking, Derrida agrees with Quine both on the nature of meaning and on the related view that "our theory" cannot be abandoned all at once. Thus a philosopher must by and large think about a logocentric philosophical theory that has shaped our language in the very logocentric terms that that theory has shaped. Thus deconstruction is not an excision of criticized doctrines, but a much more complicated, self-referential relationship.

Deconstructive arguments work out the consequences of there being nothing helpfully better than words, i.e. of thoroughgoing nominalism. According to Derrida, without *logoi* fundamental philosophical contrasts lose their principled foundations, since such contrasts implicitly posit one term as a *logos* relative to which the other side is defective. Without *logos*, many contrasts cannot be made to function as principles of the sort of theory philosophy has sought. Thus the contrasts between metaphorical and literal, rhetoric and logic, and other central notions of philosophy are shown not to have the foundation that their use presupposes.

See also HEIDEGGER, HUSSERL, MEANING, PHILOSOPHY OF LANGUAGE. S.C.W.

Dedekind, Richard (1831–1916), German mathematician, one of the most important figures in the mathematical analysis of foundational questions that took place in the late nineteenth century. Philosophically, three things are interesting about Dedekind's work: (1) the insistence that the fundamental numerical systems of mathematics must be developed independently of spatiotemporal or geometrical notions; (2) the insistence that the number systems rely on certain mental capacities fundamental to thought, in particular on the capacity of the mind to "create"; and (3) the recognition that this "creation" is "creation" according to certain key properties, properties that careful mathematical analysis reveals as essential to the subject matter. (1) is a concern Dedekind shared with Bolzano, Cantor, Frege, and Hilbert; (2) sets Dedekind apart from Frege; and (3) represents a distinctive shift toward the later axiomatic position of Hilbert and somewhat away from the concern with the individual nature of the central abstract mathematical objects which is a central concern of Frege. Much of Dedekind's position is sketched in the *Habilitationsrede* of 1854, the procedure there being applied in outline to the extension of the positive whole numbers to the integers, and then to the rational field. However, the two works best known to philosophers are the monographs on irrational numbers (*Stetigkeit und irrationale Zahlen*, 1872) and on natural numbers (*Was sind und was sollen die Zahlen?* 1888), both of which pursue the procedure advocated in 1854. In both we find an "analysis" designed to uncover the essential properties involved, followed by a "synthesis" designed to show that there can be such systems, this then followed by a "creation" of objects possessing the properties and nothing more.

In the 1872 work, Dedekind suggests that the essence of continuity in the reals is that whenever the line is divided into two halves by a *cut*, i.e. into two subsets A_1 and A_2 such that if $p \in A_1$ and $q \in A_2$, then $p < q$ and, if $p \in A_1$ and $q < p$, then $q \in A_1$, and if $p \in A_2$ and $q > p$, then $q \in A_2$ as well, then there is real number r which "produces" this cut, i.e. such that $A_1 = \{p; p < r\}$, and $A_2 = \{p: r \leq p\}$. The task is then to characterize the real numbers so that this is indeed true of them. Dedekind shows that, whereas the rationals themselves do not have this property, the collection of all *cuts* in the rationals does. Dedekind then "defines" the irrationals through this observation, not directly as the cuts in the rationals themselves, as was done later, but rather through the "creation" of "new (irrational) numbers" to correspond to those rational cuts not hitherto "produced" by a number.

The 1888 work starts from the notion of a "mapping" of one object onto another, which for Dedekind is necessary for all exact thought. Dedekind then develops the notion of a one-to-one into mapping, which is then used to characterize infinity ("Dedekind infinity"). Using the fundamental notion of a chain, Dedekind characterizes the notion of a "simply infinite system," thus one that is isomorphic to the natural number sequence. Thus, he succeeds in the goal set out in the 1854 lecture: isolating *precisely* the characteristic properties of the natural number system. But do simply infinite systems, in particular the natural number system, exist? Dedekind now argues: Any infinite system must contain a simply infinite system (Theorem 72). Correspondingly, Dedekind sets out to prove that there are infinite systems (Theorem 66), for which he uses an infamous argument (reminiscent of Bolzano's from thirty years earlier) involving "my thought-world," etc. It is generally agreed that the argument does not work, although it is important to remember Dedekind's wish to demonstrate that since the numbers are to be free creations of the human mind, his proofs should rely only on the properties of the mental. The specific act of "creation," however, comes in when Dedekind, starting from any simply infinite system, abstracts from the "particular properties" of this, claiming that what results is the simply infinite system of the natural numbers.

Dedekind cut. See DEDEKIND.

***de dicto*,** of what is said (or of the proposition), as opposed to *de re*, of the thing. Many philosophers believe the following to be ambiguous, depending on whether they are interpreted *de dicto* or *de re:*

(1) It is possible that the number of U.S. states is even.
(2) Galileo believes that the earth moves.

Assume for illustrative purposes that there are propositions and properties. If (1) is interpreted as *de dicto*, it asserts that the proposition that the number of U.S. states is even is a possible truth – something true, since there are in fact fifty states. If (1) is interpreted as *de re*, it asserts that the actual number of states (fifty) has the property of being possibly even – something essentialism takes to be true. Similarly for (2); it may mean that Galileo's belief has a certain content – that the earth moves – or that Galileo believes, *of* the earth, that it moves.

More recently, due largely to Castañeda and Perry, many philosophers have come to believe in *de se* (of oneself) ascriptions, distinct from *de dicto* and *de re*. Suppose, while drinking with others, I notice that someone is spilling beer. Later I come to realize that it is I. I believed at the outset that someone was spilling beer, but didn't believe that *I* was. Once I did, I straightened my glass. The distinction between *de se* and *de dicto* attributions is supposed to be supported by the fact that while *de dicto* propositions must be either true or false, there is no *true* proposition embeddable within 'I believe that . . .' that correctly ascribes to me the belief that I myself am spilling beer. The sentence 'I am spilling beer' will not do, because it employs an "essential" indexical, 'I'. Were I, e.g., to designate myself other than by using 'I' in attributing the relevant belief to myself, there would be no explanation of my straightening my glass. Even if I believed *de re* that LePore is spilling beer, this still does not account for why I lift my glass. For I might not know I am LePore. On the basis of such data, some philosophers infer that *de se* attributions are irreducible to *de re* or *de dicto* attributions.

***de dicto* necessity.** See NECESSITY.

deducibility relation. See DEDUCTION, Appendix of Special Symbols.

deduction, a finite sequence of sentences whose last sentence is a conclusion of the sequence (the one said to be deduced) and which is such that each sentence in the sequence is an axiom or a premise or follows from preceding sentences in the sequence by a rule of inference. A synonym is 'derivation'. Deduction is a system-relative concept. It makes sense to say something is a deduction only relative to a particular system of axioms and rules of inference. The very same sequence of sentences might be a deduction relative to one such system but not relative to another.

The concept of deduction is a generalization of the concept of proof. A proof is a finite sequence of sentences each of which is an axiom or follows from preceding sentences in the sequence by a rule of inference. The last sentence in the sequence is a theorem. Given that the system of axioms and rules of inference are effectively specifiable, there is an effective procedure for determining, whenever a finite sequence of sentences is given, whether it is a proof relative to that system. The notion of theorem is not in general effective (decidable). For there may be no method by which we can always find a proof of a given sentence or determine that none exists.

The concepts of deduction and consequence are distinct. The first is syntactical; the second is semantical. It was a discovery that, relative to the axioms and rules of inference of classical logic, a sentence *S* is deducible from a set of sentences *K* provided that *S* is a consequence of *K*. Compactness is an important consequence of this discovery. It is trivial that sentence *S* is deducible from *K* just in case *S* is deducible from some finite subset of *K*. It is not trivial that *S* is a consequence of *K* just in case *S* is a consequence of some finite subset of *K*. This compactness property had to be shown.

A system of natural deduction is axiom-less. Proofs of theorems within a system are generally easier with natural deduction. Proofs of theorems about a system, such as the results mentioned in the preceding paragraph, are generally easier if the system has axioms.

In a secondary sense, 'deduction' refers to an inference in which a speaker claims the conclusion follows necessarily from the premises.

deduction theorem, a result concerning certain systems of formal logic relating derivability and the conditional. It states that if a formula B is derivable from A (and possibly other assumptions), then the formula $A \rightarrow B$ is derivable without the assumption of A: in symbols, if $\Gamma \cup \{A\} \vdash B$ then $\Gamma \vdash A \rightarrow B$. The thought is that, e.g., if 'Socrates is mortal' is derivable from the assumptions 'All men are mortal' and 'Socrates is a man', then 'If Socrates is a man he is mortal' is derivable from 'All men are mortal'. Likewise, 'If all men are mortal' then 'Socrates is mortal' is derivable from 'Socrates is a man'. In general, the deduction theorem is a significant result only for axiomatic or Hilbert-style formulations of logic. In most natural deduction formulations a rule of conditional proof explicitly licenses derivations of $A \rightarrow B$ from $\Gamma \cup \{A\}$, and so there is nothing to prove. **See also** **DEDUCTION.** S.T.K.

default logic, a formal system for reasoning with defaults, developed by Raymond Reiter in 1980. Reiter's defaults have the form '$P{:}MQ_1, \ldots, MQ_n/R$', read 'If P is believed and $Q_1 \ldots Q_n$ are consistent with one's beliefs, then R may be believed'. Whether a proposition is consistent with one's beliefs depends on what defaults have already been applied. Given the defaults $P{:}MQ/Q$ and $R{:}M{\sim}Q/{\sim}Q$, and the facts P and R, applying the first default yields Q while applying the second default yields ${\sim}Q$. So applying either default blocks the other. Consequently, a default theory may have several default extensions.

Normal defaults having the form $P{:}MQ/Q$, useful for representing simple cases of nonmonotonic reasoning, are inadequate for more complex cases. Reiter produces a reasonably clean proof theory for normal default theories and proves that every normal default theory has an extension.

See also **DEFEASIBILITY, NON-MONOTONIC LOGIC.** D.N.

defeasibility, a property that rules, principles, arguments, or bits of reasoning have when they might be *defeated* by some competitor. For example, the epistemic principle 'Objects normally have the properties they appear to have' and the normative principle 'One should not lie' are defeated, respectively, when perception occurs under unusual circumstances (e.g., under colored lights) or when there is some overriding moral consideration (e.g., to prevent murder). Apparently declarative sentences such as 'Birds typically fly' can be taken in part as expressing defeasible rules: take something's being a bird as evidence that it flies. Defeasible arguments and reasoning inherit their defeasibility from the use of defeasible rules or principles.

Recent analyses of defeasibility include circumscription and default logic, which belong to the broader category of nonmonotonic logic. The rules in several of these formal systems contain special antecedent conditions and are not truly defeasible since they apply whenever their conditions are satisfied. Rules and arguments in other nonmonotonic systems justify their conclusions only when they are not defeated by some other fact, rule, or argument. John Pollock distinguishes between *rebutting* and *undercutting* defeaters. 'Snow is not normally red' rebuts (in appropriate circumstances) the principle 'Things that look red normally are red', while 'If the available light is red, do not use the principle that things that look red normally are red' only undercuts the embedded rule. Pollock has influenced most other work on formal systems for defeasible reasoning.

defeat of reasons. See EPISTEMOLOGY, JUSTIFICATION.

definiendum (plural: definienda), the expression that is defined in a definition. The expression that gives the definition is the definiens (plural: definientia). In the definition '*father*, male parent', 'father' is the definiendum and 'male parent' is the definiens. In the definition 'A human being is a rational animal', 'human being' is the definiendum and 'rational animal' is the definiens. Similar terms are used in the case of conceptual analyses, whether they are meant to provide synonyms or not: 'analysandum' for 'definiendum' and 'analysans' for 'definiens'. In 'x knows that p if and only if it is true that p, x believes that p, and x's belief that p is properly justified', 'x knows that p' is the analysandum and 'it is true that p, x believes that p, and x's belief that *p* is properly justified' is the analysans. **See also** ANALYSIS, DEFINITION, MEANING. T.Y.

definiens. See DEFINIENDUM.

definist, someone who holds that moral terms, such as 'right', and evaluative terms, such as 'good' – in short, *normative* terms – are definable in non-moral, non-evaluative (i.e., non-normative) terms. Frankena offers a broader account of a definist as one who holds that ethical terms are definable in non-ethical terms. This would allow that they are definable in non-ethical but evaluative terms – say, 'right' in terms of what is non-morally intrinsically good. Definists who are also naturalists hold that moral terms can be defined by terms that denote natural properties, i.e. properties whose presence or absence can be determined by observational means. They might define 'good' as 'what conduces to pleasure'. Definists who are not naturalists will hold that the terms that do the defining do not denote natural properties, e.g. that 'right' means 'what is commanded by God'. **See also** ETHICS, MOORE, NATURALISM. B.R.

definist fallacy. See MOORE.

definite description. See THEORY OF DESCRIPTIONS.

definite description operator. See Appendix of Special Symbols.

definition, specification of the meaning or, alternatively, conceptual content of an expression. For example, 'period of fourteen days' is a definition of 'fortnight'. Definitions have traditionally been judged by rules like the following:

(1) A definition should not be too narrow. 'Unmarried adult male psychiatrist' is too narrow a definition for 'bachelor', for some bachelors are not psychiatrists. 'Having vertebrae and a liver' is too narrow for 'vertebrate', for, even though all actual vertebrate things have vertebrae and a liver, it is possible for a vertebrate thing to lack a liver.
(2) A definition should not be too broad. 'Unmarried adult' is too broad a definition for 'bachelor', for not all unmarried adults are bachelors. 'Featherless biped' is too broad for 'human being', for even though all actual featherless bipeds are human beings, it is possible for a featherless biped to be non-human.
(3) The defining expression in a definition should (ideally) exactly match the degree of vagueness of the expression being defined (except in a precising definition). 'Adult female' for 'woman' does not violate this rule, but 'female at least eighteen years old' for 'woman' does.
(4) A definition should not be circular. If 'desirable' defines 'good' and 'good' defines 'desirable', these definitions are circular.

Definitions fall into at least the following kinds:

Analytical definition: definition whose corresponding biconditional is analytic or gives an analysis of the *definiendum:* e.g., 'female fox' for 'vixen', where the corresponding biconditional 'For any *x*, *x* is a vixen if and only if *x* is a female fox' is analytic; 'true in all possible worlds' for 'necessarily true', where the corresponding biconditional 'For any *P*, *P* is necessarily true if and only if *P* is true in all possible worlds' gives an analysis of the *definiendum*.

Contextual definition: definition of an expression as it occurs in a larger expression: e.g., 'If it is not the case that *Q*, then *P*' contextually defines 'unless' as it occurs in '*P* unless *Q*'; 'There is at least one entity that is *F* and is identical with any entity that is *F*' contextually defines 'exactly one' as it occurs in 'There is exactly one *F*'. Recursive definitions (see below) are an important variety of contextual definition. Another important application of contextual definition is Russell's theory of descriptions, which defines 'the' as it occurs in contexts of the form 'The so-and-so is such-and-such'.

Coordinative definition: definition of a theoretical term by non-theoretical terms: e.g., 'the forty-millionth part of the circumference of the earth' for 'meter'.

Definition by genus and species: When an expression is said to be applicable to some but not all entities of a certain type and inapplicable to all entities not of that type, the type in question is the genus, and the subtype of all and only those entities to which the expression is applicable is the species: e.g., in the definition 'rational animal' for 'human', the type *animal* is the genus and the subtype *human* is the species. Each species is distinguished from any other of the same genus by a property called the *differentia*, e.g. *rational* in the above definition.

Definition in use: specification of how an expression is used or what it is used to express: e.g., ‘uttered to express astonishment’ for ‘my goodness’. Wittgenstein emphasized the importance of definition in use in his use theory of meaning.

Definition per genus et differentiam: definition by genus and difference; same as definition by genus and species.

Explicit definition: definition that makes it clear that it is a definition and identifies the expression being defined as such: e.g., ‘Father’ means ‘male parent’; ‘For any *x, x* is a father by definition if and only if *x* is a male parent’.

Implicit definition: definition that is not an explicit definition.

Lexical definition: definition of the kind commonly thought appropriate for dictionary definitions of natural language terms, namely a specification of their conventional meaning.

Nominal definition: definition of a noun (usually a common noun), giving its linguistic meaning. Typically it is in terms of macrosensible characteristics: e.g., ‘yellow malleable metal’ for ‘gold’. Locke spoke of nominal essence and contrasted it with real essence.

Ostensive definition: definition by an example in which the referent is specified by pointing or showing in some way: e.g., ‘“Red” is *that* color’, where the word ‘that’ is accompanied with a gesture pointing to a patch of colored cloth; ‘“Pain” means *this*’, where ‘*this*’ is accompanied with an insertion of a pin through the hearer’s skin; ‘“Kangaroo” applies to all and only animals like *that*’, where ‘*that*’ is accompanied by pointing to a particular kangaroo.

Persuasive definition: definition designed to affect or appeal to the psychological states of the party to whom the definition is given, so that a claim will appear more plausible to the party than it is: e.g., ‘self-serving manipulator’ for ‘politician’, where the claim in question is that all politicians are immoral.

Precising definition: definition of a vague expression intended to reduce its vagueness: e.g., ‘snake longer than half a meter and shorter than two meters’ for ‘snake of average length’; ‘having assets ten thousand times the median figure’ for ‘wealthy’.

Prescriptive definition: stipulative definition that, in a recommendatory way, gives a new meaning to an expression with a previously established meaning: e.g., ‘male whose primary sexual preference is for other males’ for ‘gay’.

Real definition: specification of the metaphysically necessary and sufficient condition for being the kind of thing a noun (usually a common noun) designates: e.g., ‘element with atomic number 79’ for ‘gold’. Locke spoke of real essence and contrasted it with nominal essence.

Recursive definition (also called inductive definition and definition by recursion): definition in three clauses in which (1) the expression defined is applied to certain particular items (the base clause); (2) a rule is given for reaching further items to which the expression applies (the recursive, or inductive, clause); and (3) it is stated that the expression applies to nothing else (the closure clause). For example, ‘John’s parents are John’s *ancestors;* any parent of John’s ancestor is John’s ancestor; nothing else is John’s ancestor’. By the base clause, John’s mother and father are John’s ancestors. Then by the recursive clause, John’s mother’s parents and John’s father’s parents are John’s ancestors; so are their parents, and so on. Finally, by the last (closure) clause, these people exhaust John’s ancestors. The following defines multiplication in terms of addition: ‘$0 \times n = 0$. $(m + 1) \times n = (m \times n) + n$. Nothing else is the result of multiplying integers’. The base clause tells us, e.g., that $0 \times 4 = 0$. The recursive clause tells us, e.g., that $(0 + 1) \times 4 = (0 \times 4) + 4$. We then know that $1 \times 4 = 0 + 4 = 4$. Likewise, e.g., $2 \times 4 = (1 + 1) \times 4 = (1 \times 4) + 4 = 4 + 4 = 8$.

Stipulative definition: definition regardless of the ordinary or usual conceptual content of the expression defined. It postulates a content, rather than aiming to capture the content already associated with the expression. Any explicit definition that introduces a new expression into the language is a stipulative definition: e.g., ‘For the purpose of our discussion “existent” means “perceivable”‘; ‘By “zoobeedoobah” we shall mean “vain millionaire who is addicted to alcohol”‘.

Synonymous definition: definition of a word (or other linguistic expression) by another word synonymous with it: e.g., 'buy' for 'purchase'; 'madness' for 'insanity'.

degenerate case, an expression used more or less loosely to indicate an individual or class that falls outside of a given background class to which it is otherwise very closely related, often in virtue of an ordering of a more comprehensive class. A degenerate case of one class is often a limiting case of a more comprehensive class. Rest (zero velocity) is a degenerate case of motion (positive velocity) while being a limiting case of velocity. The circle is a degenerate case of an equilateral and equiangular polygon. In technical or scientific contexts, the conventional term for the background class is often "stretched" to cover otherwise degenerate cases. A figure composed of two intersecting lines is a degenerate case of hyperbola in the sense of synthetic geometry, but a limiting case of hyperbola in the sense of analytic geometry. The null set is a degenerate case of set in an older sense but a limiting case of set in a modern sense. A line segment is a degenerate case of rectangle when rectangles are ordered by ratio of length to width, but not a limiting case under these conditions. **See also** BORDERLINE CASE, LIMITING CASE. J.Cor.

degree, also called arity, adicity, in formal languages, a property of predicate and function expressions that determines the number of terms with which the expression is correctly combined to yield a well-formed expression. If an expression combines with a single term to form a well-formed expression, it is of *degree one* (*monadic, singulary*). Expressions that combine with two terms are of *degree two* (*dyadic, binary*), etc. Expressions of degree greater than or equal to two are *polyadic*. The formation rules of a formalized language must effectively specify the degrees of its primitive expressions as part of the effective determination of the class of well-formed formulas. Degree is commonly indicated by an attached superscript consisting of an Arabic numeral. Formalized languages have been studied that contain expressions having *variable degree* (or *variable adicity*) and that can thus combine with any finite number of terms. An abstract relation that would be appropriate as an extension of a predicate expression is subject to the same terminology, and likewise for function expressions and their associated functions. **See also** FORMAL LANGUAGE, MATHEMATICAL FUNCTION, PROPERTY. C.A.A.

degree of belief. See BAYESIAN RATIONALITY, PROBABILITY.

degree of confirmation. See CARNAP.

degree of unsolvability, a maximal set of equally complex sets of natural numbers, with comparative complexity of sets of natural numbers construed as recursion-theoretic reducibility ordering. Recursion theorists investigate various notions of reducibility between sets of natural numbers, i.e. various ways of filling in the following schematic definition. For sets *A* and *B* of natural numbers: *A* is reducible to *B* iff (if and only if) there is an algorithm whereby each membership question about *A* (e.g., '$17 \in A$?') could be answered allowing consultation of an "oracle" that would correctly answer each membership question about *B*. This does not presuppose that there is a "real" oracle for *B;* the motivating idea is counterfactual: *A* is reducible to *B* iff: if membership questions about *B* were decidable then membership questions about *A* would also be decidable. On the other hand, the mathematical definitions of notions of reducibility involve no subjunctive conditionals or other intensional constructions. The notion of reducibility is determined by constraints on how the algorithm could use the oracle. Imposing no constraints yields *T-reducibility* ('*T*' for Turing), the most important and most studied notion of reducibility.

Fixing a notion *r* of reducibility: *A* is *r*-equivalent to *B* iff *A* is *r*-reducible to *B* and *B* is *r*-reducible to *A*. If *r*-reducibility is transitive, *r*-equivalence is an equivalence relation on the class of sets of natural numbers, one reflecting a notion of equal complexity for sets of natural numbers. A degree of unsolvability relative to r (an r-degree) is an equivalence class under that equivalence relation, i.e. a maximal class of sets of natural numbers any two members of which are r-equivalent, i.e. a maximal class of equally complex (in the sense of r-reducibility) sets of natural numbers. The r-reducibility-ordering of sets of natural numbers transfers to the r-degrees: for d and d' r-degrees, let $d \le d'$ iff for some $A \in d$ and $B \in d'$ A is r-reducible to B. The study of r-degrees is the study of them under this ordering.

The degrees generated by T-reducibility are the Turing degrees. Without qualification, 'degree of unsolvability' means 'Turing degree'. The least T-degree is the set of all recursive (i.e., using Church's thesis, solvable) sets of natural numbers. So the phrase 'degree of *un*solvability' is slightly misleading: the least such degree is "solvability."

By effectively coding functions from natural numbers to natural numbers as sets of natural numbers, we may think of such a function as belonging to a degree: that of its coding set.

Recursion theorists have extended the notions of reducibility and degree of unsolvability to other domains, e.g. transfinite ordinals and higher types taken over the natural numbers.

See also CHURCH'S THESIS, PHILOSOPHY OF MATHEMATICS, RECURSIVE FUNCTION THEORY. H.T.H.

degrees of belief, a feature of an agent's doxastic state, according to the tradition of formal epistemology; also called *credences* or *partial beliefs*. While an important part of epistemology concerns "full" or "on-off" beliefs – one either believes something or does not – there is another way to represent one's epistemic attitude toward a proposition that admits of degrees. The basic idea goes back to at least John Locke, but the first formal and systematic treatments of beliefs that come in degrees are Frank Ramsey's "Truth and Probability" (1926) and Bruno de Finetti's "La prevision" (1937). One's degree of belief in p is generally measured or defined by the bets one is willing to take on p. For example, one believes p to degree 0.6 if one is willing to pay $0.60 for a bet that yields $1 if p and $0 otherwise.

Probabilism is the thesis that the degrees of belief of a rational agent obey the axioms of probability theory: $0 \le \mathrm{Cr}(p) \le 1$, $\mathrm{Cr}(p) = 1$ if p is a tautology, and $\mathrm{Cr}(p \vee q) = \mathrm{Cr}(p) + \mathrm{Cr}(q)$ for mutually exclusive p and q. Additionally, where $\mathrm{Cr}(p \mid q)$ is the agent's conditional credence in p given q, $\mathrm{Cr}(p \,\&\, q) = \mathrm{Cr}(q)\mathrm{Cr}(p \mid q)$. There are a number of different ways to argue for probabilism. One type of argument, the Dutch book argument, shows that agents with credences that violate these axioms will be willing to take bets that result in sure loss. Another type of argument, the scoring rule argument, represents an individual as deriving value ("epistemic utility") from how close to the truth she is on various propositions. Scoring rule arguments show that if the agent has non-probabilistic credences, then there are other credences that do better from her own point of view in terms of maximizing (expected) epistemic utility. A final type of argument, the representation theorem argument, shows that if an individual has rational preferences – preferences that conform to particular axioms – then she will be representable by a unique probabilistic credence function.

See also BAYESIAN EPISTEMOLOGY, CONDITIONALIZATION, FORMAL EPISTEMOLOGY. L.Bu.

deism, the view that true religion is natural religion. Some self-styled Christian deists accepted revelation, although they argued that its content is essentially the same as that of natural religion. Most deists dismissed revealed religion as a fiction. God wants his creatures to be happy and has ordained virtue as the means to it. Since God's benevolence is disinterested, he will ensure that the knowledge needed for happiness is universally accessible. Salvation cannot, then, depend on special revelation. True religion is an expression of a universal human nature whose essence is reason and is the same in all times and places. Religious traditions such as Christianity and Islam originate in credulity, political tyranny, and priestcraft, which corrupt reason and overlay natural religion with impurities. Deism is largely a seventeenth- and eighteenth-century phenomenon and was most prominent in England. Among the important English deists were John Toland (1670–1722), Anthony Collins (1676–1729), Herbert of Cherbury (1583–1648), Matthew Tindal (1657–1733), and Thomas Chubb (1679–1747). Continental deists included Voltaire and Reimarus. Thomas Paine and Elihu Palmer (1764–1806) were prominent American deists. Orthodox writers in this period use 'deism' as a vague term of abuse. By the late eighteenth century, the term came to mean belief in an "absentee God" who creates the world, ordains its laws, and then leaves it to its own devices. **See also** PHILOSOPHY OF RELIGION. W.J.Wa.

deity, in a wide sense, a person or agent seen as having super-human power and, typically, non-human or super-human form (as with Zeus); in a narrower sense, a person or agent taken to be divine: a god. If a deity instantiates certain great-making properties, as does God in perfect being theology in Anselm, Aquinas, Descartes, Spinoza, and later philosophers, including Plantinga and Swinburne at this writing, it may be considered not only a god (or God) but worthy of reverence, worship, and (in some traditions) unconditional obedience. The perfect being theology – also sometimes called *philosophy of God* – found in these authors has generated a massive literature on divine attributes.

'Deity' is also sometimes understood as characterizing a being (commonly without presupposing its existence) that, in given religious traditions, is recognized as divine. In this usage, 'deity' is a relative term: the deity in some religions is not recognized as divine in other traditions. For example, in Islam Jesus Christ is recognized as a prophet but not as divine, and, from the standpoint of monotheism, polytheism has historically been seen as a form of idolatry, mistakenly treating as a god or divine that which is neither.

See also DIVINE ATTRIBUTES, PHILOSOPHY OF RELIGION. C.C.T.

de la Ramée, Pierre. See RAMUS.

Deleuze, Gilles (1925–95), French philosopher who, along with Foucault (1926–84) and Derrida (1930–2004), was among the dominant figures in French philosophy in the second half of the twentieth century. Although critical of the French tradition of historical scholarship, Deleuze produced studies in the history of philosophy, with books on Hume (*Empiricism and Subjectivity: An Essay on Hume's Theory of Human Nature*, 1953), Nietzsche (*Nietzsche and Philosophy*, 1962), Kant (*Kant's Critical Philosophy: The Doctrine of the Faculties*, 1963), Bergson (*Bergsonism*, 1966), Spinoza (*Expressionism in Philosophy: Spinoza*, 1968, and *Spinoza, Practical Philosophy*, 1970, rev. 1981), and Leibniz (*The Fold: Leibniz and the Baroque*, 1988). Several of these works had significant influence: his work on Nietzsche, which focused on active and reactive forces and set Nietzsche in opposition to Hegel, was a major factor in the development of interest in Nietzsche in France in the 1960s. His book on Kant was among the first to argue that Kant's *Critique of Judgment* should be read as the *telos* toward which Kant's entire critical project was directed. His books on Spinoza influenced several generations of French Spinozism, and his work on Bergson is widely credited with rehabilitating Bergson's philosophical reputation. His text on his friend Foucault deserves mention: *Foucault* (1986).

Deleuze was more comfortable engaging central questions of metaphysics than many of his French contemporaries; *Difference and Repetition* (1968), regarded by many as his magnum opus, offers a metaphysical justification for the priority of difference over identity and stands as one of the foundational texts of the philosophy of difference that characterizes much poststructuralist philosophy. This work was followed by *The Logic of Sense* (1969), in which Deleuze uses resources from analytic philosophy as well as Stoicism to examine the genesis and structure of sense through a reading of Lewis Carroll.

Deleuze was introduced to most English readers through work coauthored with radical psychoanalyst Félix Guattari. Their *Capitalism and Schizophrenia: Anti-Oedipus* (1972) was read as a major articulation of the philosophy of desire and a profound critique of psychoanalysis. Their collaboration continued through *Kafka: Toward a Minor Literature* (1975), *Capitalism and Schizophrenia II: A Thousand Plateaus* (1980), and *What Is Philosophy?* (1991). Deleuze's writings were not limited to philosophy or social criticism. His 1964 *Proust and Signs* remains a classic of Proust scholarship, and his two works on cinema in the field of film studies – *Cinema 1: The Movement-Image* (1983) and *Cinema 2: The Time Image* (1985) – are likewise highly regarded. Literature engages him as well in *Essays Critical and Clinical* (1993) and *Masochism: An Interpretation of Coldness and Cruelty* (1967), on Leopold Sacher-Masoch.

deliberation. See ACTION THEORY, PRACTICAL REASONING.

deliberative democracy, a kind of democracy in which political deliberation plays a major role in democratic decision making and is seen as essential for the political legitimacy of government. The term also names a family of views in democratic theory committed to the claim that the legitimacy of democratic government and the authority of its laws are owed to the role that public deliberation (sometimes called public reasoning) plays in democratic decision-making processes.

The deliberative democrat opposes two alternative programs in democratic theory. The first – *strict proceduralism* – holds that democratic laws are authoritative in virtue of being produced by a decision procedure having certain formal characteristics, such as fairness, equality of input, and majority rule. The second – the *correctness theory* – holds that democratic laws are authoritative only if correct according to some procedure-independent moral standard. The democratic credentials of correctness theories are dubious, since democracy is probably not an adequate or reliable mechanism for reaching substantively correct decisions. Pure proceduralism raises difficulties because an election could satisfy the stated procedural requirements despite being objectionable in ways that seem to undermine the authority of its results. An ignorant, misinformed, deluded, or bigoted electorate could conduct a fair, equal, majoritarian election. Deliberative democrats contend that fair, equal, majoritarian decision procedures are necessary, but not sufficient, for democratic legitimacy and authority. What is also required is a system of institutions and forums in civil society where individuals as equal citizens can share and exchange their reasons and arguments concerning public policy. The deliberative democrat, then, holds that democratic decisions owe their authority to a basis in a fair, egalitarian, majoritarian decision procedure preceded by episodes of public deliberation among citizens under conditions of equality. In this way, deliberative democratic theories combine the reason-recognizing feature of correctness theories with the proceduralism of strict proceduralist views.

R.B.T.

de Maistre, Joseph-Marie (1753–1821), French political theorist, diplomat, and Roman Catholic exponent of theocracy. He was educated by the Jesuits in Turin. His counterrevolutionary political philosophy aimed at restoring the foundations of morality, the family, society, and the state in postrevolutionary Europe. Against Enlightenment ideals, he reclaimed Thomism, defended the hereditary and absolute monarchy, and championed ultramontanism (*The Pope*, 1821). *Considerations on France* (1796) argues that the decline of moral and religious values was responsible for the "satanic" 1789 revolution. Hence Christianity and Enlightenment philosophy were engaged in a fight to the death that he claimed the church would eventually win. Deeply pessimistic about human nature, the *Essay on the Generating Principle of Political Constitutions* (1810) traces the origin of authority in the human craving for order and discipline. *Saint Petersburg Evenings* (1821) urges philosophy to surrender to religion and reason to faith. J.-L.S.

demandingness, an objectionable consequence initially invoked against utilitarianism and other consequentialist moral theories, alleging that they generate implausible demands, demands to make sacrifices that range beyond what either morality or reason can plausibly be taken to require.

Virtually all moral theories require people to make sacrifices, and most require extreme personal sacrifice in some cases. They might, e.g., prohibit me, at great personal sacrifice, from illicitly advancing my name on an organ transplant list, but even such extreme sacrifices do not trigger the demandingness objection if the prohibitions in question nonetheless seem reasonable or morally rightful. It is triggered instead by theories that demand sacrifices beyond what common sense suggests is reasonable or morally rightful. Thus, some form of a requirement that those with ample resources give to those with inadequate resources, hence that they make certain limited personal sacrifices, can seem both reasonable and rightful. But a theory that morally requires the former to spend themselves down to the level of the latter can seem to make demands that are both (1) unreasonable, since it fails to take into account the good agent-relative reasons that we each seem to have for giving disproportionate weight to our own plans, projects, commitments, and well-being, and (2) morally implausible, since a plausible moral theory will at most permit such selfless action, not require it. It is such requirements that trigger the demandingness objection against a moral theory that generates them. The objection can be traced back in some form at least to J. S. Mill. More recently, Samuel Scheffler's development of the objection has stimulated a great deal of subsequent development and discussion.

demarcation, the line separating empirical science from mathematics and logic, from metaphysics, and from pseudoscience. Science traditionally was supposed to rely on induction, the formal disciplines (including metaphysics) on deduction. In the verifiability criterion, the logical positivists identified the demarcation of empirical science from metaphysics with the demarcation of the cognitively meaningful from the meaningless, classifying metaphysics as gibberish, and logic and mathematics, more charitably, as without sense. Noting that, because induction is invalid, the theories of empirical science are unverifiable, Popper proposed falsifiability as their distinguishing characteristic, and remarked that some metaphysical doctrines, such as atomism, are obviously meaningful. It is now recognized that science is suffused with metaphysical ideas, and Popper's criterion is therefore perhaps a (rather rough) criterion of demarcation of the empirical from the non-empirical rather than of the scientific from the non-scientific. It repudiates the unnecessary task of demarcating the cognitively meaningful from the cognitively meaningless. **See also** FALSIFIABILITY, INDUCTION, MEANING, METAPHYSICS, POPPER, VERIFIABILITY. D.W.M.

demiurge (from Greek *dēmiourgos*, 'artisan', 'craftsman'), a deity who shapes the material world from the preexisting chaos. Plato introduces the demiurge in his *Timaeus*. Because he is perfectly good, the demiurge wishes to communicate his own goodness. Using the Forms as a model, he shapes the initial chaos into the best possible image of these eternal and immutable archetypes. The visible world is the result. Although the demiurge is the highest god and the best of causes, he should not be identified with the God of theism. His ontological and axiological status is lower than that of the Forms, especially the Form of the Good. He is also limited. The material he employs is not created by him. Furthermore, it is disorderly and indeterminate, and thus partially resists his rational ordering. In gnosticism, the demiurge is the ignorant, weak, and evil or else morally limited cause of the cosmos. In the modern era the term has occasionally been used for a deity who is limited in power or knowledge. Its first occurrence in this sense appears to be in J. S. Mill's *Theism* (1874). **See also** GNOSTICISM, PHILOSOPHY OF RELIGION, PLATO. W.J.Wa.

democracy. See POLITICAL PHILOSOPHY.

Democritus (c.460–c.370 B.C.), Greek pre-Socratic philosopher. He was born at Abdera, in Thrace. Building on Leucippus and his atomism, he developed the atomic theory in *The Little World-System* and numerous other writings. In response to the Eleatics' argument that the impossibility of not-being entailed that there is no change, the atomists posited the existence of a plurality of tiny indivisible beings – the atoms – and not-being – the void, or empty space. Atoms do not come into being or perish, but they do move in the void, making possible the existence of a world, and indeed of many worlds. For the void is infinite in extent, and filled with an infinite number of atoms that move and collide with one another. Under the right conditions a concentration of atoms can begin a vortex motion that draws in other atoms and forms a spherical heaven enclosing a world. In our world there is a flat earth surrounded by heavenly bodies carried by a vortex motion. Other worlds like ours are born, flourish, and die, but their astronomical configurations may be different from ours and they need not have living creatures in them.

The atoms are solid bodies with countless shapes and sizes, apparently having weight or mass, and capable of motion. All other properties are in some way derivative of these basic properties. The cosmic vortex motion causes a sifting that tends to separate similar atoms as the sea arranges pebbles on the shore. For instance, heavier atoms sink to the center of the vortex, and lighter atoms such as those of fire rise upward. Compound bodies can grow by the aggregations of atoms that become entangled with one another. Living things, including humans, originally emerged out of slime. Life is caused by fine, spherical soul atoms, and living things die when these atoms are lost. Human culture gradually evolved through chance discoveries and imitations of nature.

Because the atoms are invisible and the only real properties are properties of atoms, we cannot have direct knowledge of anything. Tastes, temperatures, and colors we know only "by convention." In general the senses cannot give us anything but "bastard" knowledge; but there is a "legitimate" knowledge based on reason, which takes over where the senses leave off – presumably demonstrating that there are atoms that the senses cannot testify of. Democritus offers a causal theory of perception – sometimes called the *theory of effluxes* – accounting for tastes in terms of certain shapes of atoms and for sight in terms of "effluences" or moving films of atoms that impinge on the eye.

Drawing on both atomic theory and conventional wisdom, Democritus develops an ethics of moderation. The aim of life is equanimity (*euthumiê*), a state of balance achieved by moderation and proportionate pleasures. Envy and ambition are incompatible with the good life.

Although Democritus was one of the most prolific writers of antiquity, his works were all lost. Yet we can still identify his atomic theory as the most fully worked out of pre-Socratic philosophies. His theory of matter influenced Plato's *Timaeus*, and his naturalist anthropology became the prototype for liberal social theories. Democritus had no immediate successors, but a century later Epicurus transformed his ethics into a philosophy of consolation founded on atomism. Epicureanism thus became the vehicle through which atomic theory was transmitted to the early modern period.

De Morgan, Augustus (1806–71), prolific British mathematician, logician, and philosopher of mathematics and logic. He is remembered chiefly for several lasting contributions to logic and philosophy of logic, including the discovery and deployment of the concept of universe of discourse, the cofounding of relational logic, the adaptation of what are now known as De Morgan's laws, and several terminological innovations including the expression 'mathematical induction'. His main logical works, the monograph *Formal Logic* (1847) and the series of articles "On the Syllogism" (1846–62), demonstrate wide historical and philosophical learning, synoptic vision, penetrating originality, and disarming objectivity. His relational logic treated a wide variety of inferences involving propositions whose logical forms were significantly more complex than those treated in the traditional framework stemming from Aristotle, e.g. 'If every doctor is a teacher, then every ancestor of a doctor is an ancestor of a teacher'. De Morgan's conception of the infinite variety of logical forms of propositions vastly widens that of his predecessors and even that of his able contemporaries such as Boole, Hamilton, Mill, and Whately. De Morgan did as much as any of his contemporaries toward the creation of modern mathematical logic. **See also** DE MORGAN'S LAWS, LOGICAL FORM, RELATIONAL LOGIC, UNIVERSE OF DISCOURSE. J.Cor.

De Morgan's laws, the logical principles

$$\sim(A \wedge B) = \sim A \vee \sim B,$$

$$\sim(A \vee B) = \sim A \wedge \sim B,$$

$$\sim(\sim A \wedge \sim B) = A \vee B,$$

and

$$\sim(\sim A \vee \sim B) = A \wedge B,$$

though the term is occasionally used to cover only the first two. **See also** DISTRIBUTIVE LAWS. G.F.S.

denial, alternative. See SHEFFER STROKE.

Dennett, Daniel C(lement) (b.1942), American philosopher, author of books on topics in philosophy of mind, free will, and evolutionary biology, and tireless advocate of the importance of philosophy for empirical work on evolution and on the nature of the mind. Dennett is perhaps best known for arguing that a creature (or, more generally, a system), *S*, possesses states of mind if and only if the ascription of such states to *S* facilitates the explanation and prediction of *S*'s behavior (*The Intentional Stance*, 1987). (*S* might be a human being, a chimpanzee, a desktop computer, or a thermostat.) In ascribing beliefs and desires to *S* we take up an attitude toward *S*, the *intentional stance*. We could just as well (although for different purposes) take up other stances: the *design stance* (we understand *S* as a kind of engineered system) or the *physical stance* (we regard *S* as a purely physical system).

It might seem that, although we often enough ascribe beliefs and desires to desktop computers and thermostats, we do not mean to do so literally – as with people. Dennett's contention, however, is that there is nothing more (or less) to having beliefs, desires, and other states of mind than being explicable by reference to such things. This, he holds, is not to demean beliefs, but only to affirm that to have a belief is to be describable in this particular way. If you are so describable, then it is true, literally true, that you have beliefs. Dennett extends this approach to consciousness, which he views not as an inwardly observable performance taking place in a "Cartesian Theater," but as a story we tell about ourselves, the compilation of "multiple drafts" concocted by neural subsystems (see *Consciousness Explained*, 1991). Elsewhere (*Darwin's Dangerous Idea*, 1995) Dennett has argued that principles of Darwinian selection apply to diverse domains, including cosmology and human culture, and offered a compatibilist account of free will with an emphasis on agents' control over their actions (*Elbow Room*, 1984). More recent books of his include *Darwin's Dangerous Idea: Evolution and the Meanings of Life* (1995), *Sweet Dreams: Philosophical Obstacles to a Science of Consciousness* (2005), and *Intuition Pumps and Other Tools for Thinking* (2013).

denotation, the thing or things that an expression applies to; extension. The term is used in contrast with 'meaning' and 'connotation'. A pair of expressions may apply to the same things, i.e. have the same denotation, yet differ in meaning: 'triangle', 'trilateral'; 'creature with a heart', 'creature with a kidney'; 'bird', 'feathered earthling'; 'present capital of France', 'City of Light'. If a term does not apply to anything, some would call it denotation-less, while others would say that it denotes the empty set. Such terms may differ in meaning: 'unicorn', 'centaur', 'square root of pi'. Expressions may apply to the same thing(s), yet bring to mind different associations, i.e. have different connotations: 'persistent', 'stubborn', 'pigheaded'; 'white-collar employee', 'office worker', 'professional paper-pusher'; 'Lewis Carroll', 'Reverend Dodgson'. There can be confusion about the denotation-connotation terminology, because this pair is used to make other contrasts. Sometimes the term 'connotation' is used more broadly, so that any difference of either meaning or association is considered a difference of connotation. Then 'creature with a heart' and 'creature with a liver' might be said to denote the same individuals (or sets) but to connote different properties.

In a second use, denotation is the semantic value of an expression. Sometimes the denotation of a general term is said to be a property, rather than the thing(s) having the property. This occurs when the denotation-connotation terminology is used to contrast the property expressed with the connotation. Thus 'persistent' and 'pig-headed' might be said to denote the same property but differ in connotation.

deontic logic, the logic of obligation and permission. There are three principal types of formal deontic systems.

(1) *Standard deontic logic*, or SDL, results from adding a pair of monadic deontic operators O and P, read as 'It ought to be that' and 'It is permissible that', respectively, to the classical propositional calculus. SDL contains the following axioms: tautologies of propositional logic, $OA \equiv {\sim}P{\sim}A$, $OA \supset {\sim}O{\sim}A$, $O(A \supset B) \supset (OA \supset OB)$, and OT, where T stands for any tautology. Rules of inference are *modus ponens* and substitution (see the survey of SDL by Dagfinn Føllesdal and Risto Hilpinen in R. Hilpinen, ed., *Deontic Logic*, 1971).

(2) *Dyadic deontic logic* is obtained by adding a pair of dyadic deontic operators $O(/)$ and $P(/)$, to be read as 'It ought to be that . . . , given that. . .' and 'It is permissible that . . . , given that. . .', respectively. The SDL monadic operator O is defined as $OA \equiv O(A/T)$; i.e., a statement of absolute obligation OA becomes an obligation conditional on tautologous conditions. A statement of conditional obligation $O(A/B)$ is true provided that some value realized at some B-world where A holds is better than any value realized at any B-world where A does not hold. This *axiological* construal of obligation is typically accompanied by these axioms and rules of inference: tautologies of propositional logic, *modus ponens*, and substitution, $P(A/C) \equiv {\sim}O({\sim}A/C)$, $O(A \,\&\, B/C) \equiv [O(A/C) \,\&\, O(B/C)]$, $O(A/C) \supset P(A/C)$, $O(T/C) \supset O(C/C)$, $O(T/C) \supset O(T/B \vee C)$, $[O(A/B) \,\&\, O(A/C)] \supset O(A/B \vee C)$, $[P(B/B \vee C) \,\&\, O(A/B \vee C)] \supset O(A/B)$, and $[P(\perp/C) \,\&\, O(A/B \vee C)] \supset O(A/B)$, where $\perp$ is the negation of any tautology. (See the comparison of alternative dyadic systems in Lennart Åqvist, *Introduction to Deontic Logic and the Theory of Normative Systems*, 1987.)

(3) *Two-sorted deontic logic*, due to Castañeda (*Thinking and Doing*, 1975), pivotally distinguishes between *propositions*, the bearers of truth-values, and *practitions*, the contents of commands, imperatives, requests, and such. Deontic operators apply to practitions, yielding propositions. The deontic operators Oi, Pi, Wi, and Li are read as 'It is obligatory i that', 'It is permissible i that', 'It is wrong i that', and 'It is optional i that', respectively, where i stands for any of the various types of obligation, permission, and so on. Let p stand for indicatives, where

these express propositions; let A and B stand for practitives, understood to express practitions; and allow p^* to stand for both indicatives and practitives. For deontic definition there are $PiA \equiv {\sim}Oi{\sim}A$, $WiA \equiv Oi{\sim}A$, and $LiA \equiv ({\sim}OiA \,\&\, {\sim}Oi{\sim}A)$. Axioms and rules of inference include p^*, if p^* has the form of a truth-table tautology, $OiA \supset {\sim}Oi{\sim}A$, $O1A \supset A$, where $O1$ represents *overriding obligation*, *modus ponens* for both indicatives and practitives, and the rule that if $(p \,\&\, A1 \,\&\, \ldots \,\&\, An) \supset B$ is a theorem, so too is $(p \,\&\, OiA1 \,\&\, \ldots \,\&\, OiAn) \supset OiB$.

See also DEONTIC PARADOXES, FORMAL LOGIC, MODAL LOGIC. J.E.T.

deontic operator. See DEONTIC LOGIC.

deontic paradoxes, the paradoxes of deontic logic, which typically arise as follows: a certain set of English sentences about obligation or permission appears logically consistent, but when these same sentences are represented in a proposed system of deontic logic the result is a formally inconsistent set. To illustrate, a formulation is provided below of how two of these paradoxes beset standard deontic logic.

The *contrary-to-duty imperative paradox*, made famous by Chisholm (*Analysis*, 1963), arises from juxtaposing two apparent truths: first, some of us sometimes do what we should not do; and second, when such wrongful doings occur it is obligatory that the best (or a better) be made of an unfortunate situation. Consider this scenario. Art and Bill share an apartment. For no good reason Art develops a strong animosity toward Bill. One evening Art's animosity takes over, and he steals Bill's valuable lithographs. Art is later found out, apprehended, and brought before Sue, the duly elected local punishment-and-awards official. An inquiry reveals that Art is a habitual thief with a history of unremitting parole violation. In this situation, it seems that (1)–(4) are all true (and hence mutually consistent):

(1) Art steals from Bill.
(2) If Art steals from Bill, Sue ought to punish Art for stealing from Bill.
(3) It is obligatory that if Art does not steal from Bill, Sue does not punish him for stealing from Bill.
(4) Art ought not to steal from Bill.

Turning to *standard deontic logic*, or SDL, let s stand for 'Art steals from Bill' and let p stand for 'Sue punishes Art for stealing from Bill'. Then (1)–(4) are most naturally represented in SDL as follows:

(1a) s.
(2a) $s \supset Op$.
(3a) $O({\sim}s \supset {\sim}p)$.
(4a) $O\,{\sim}s$.

Of these, (1a) and (2a) entail Op by propositional logic; next, given the SDL axiom $O(A \supset B) \supset (OA \supset OB)$, (3a) implies $O\,{\sim}s \supset O\,{\sim}p$; but the latter, taken in conjunction with (4a), entails $O\,{\sim}p$ by propositional logic. In the combination of Op, $O\,{\sim}p$, and the axiom $OA \supset {\sim}O\,{\sim}A$, of course, we have a formally inconsistent set.

The *paradox of the knower*, first presented by Lennart Åqvist (*Noûs*, 1967), is generated by these apparent truths: first, some of us sometimes do what we should not do; and second, there are those who are obligated to know that such wrongful doings occur. Consider the following scenario. Jones works as a security guard at a local store. One evening, while Jones is on duty, Smith, a disgruntled former employee out for revenge, sets the store on fire just a few yards away from Jones's work station. Here it seems that (1)–(3) are all true (and thus jointly consistent):

(1) Smith set the store on fire while Jones was on duty.
(2) If Smith set the store on fire while Jones was on duty, it is obligatory that Jones knows that Smith set the store on fire.
(3) Smith ought not set the store on fire.

Independently, as a consequence of the concept of knowledge, there is the epistemic theorem that

(4) The statement that Jones knows that Smith set the store on fire entails the statement that Smith set the store on fire.

Next, within SDL (1) and (2) surely appear to imply:

(5) It is obligatory that Jones knows that Smith set the store on fire.
(6) But (4) and (5) together yield Smith ought to set the store on fire,

given the SDL theorem that if $A \supset B$ is a theorem, so is $OA \supset OB$. And therein resides the paradox: not only does (6) appear false, the conjunction of (6) and (3) is formally inconsistent with the SDL axiom $OA \supset {\sim}O\,{\sim}A$.

The overwhelming verdict among deontic logicians is that SDL genuinely succumbs to the deontic paradoxes. But it is controversial what other approach is best followed to resolve these puzzles. Two of the most attractive proposals are Castañeda's two-sorted system (*Thinking and Doing*, 1975), and the agent-and-time relativized approach of Fred Feldman (*Philosophical Perspectives*, 1990).

deontologism, epistemic. See EPISTEMIC DEONTOLOGISM.

dependence, in philosophy, a relation of one of three main types: epistemic dependence, or dependence in the order of knowing; conceptual dependence, or dependence in the order of understanding; and ontological dependence, or dependence in the order of being. When a relation of dependence runs in one direction only, we have a relation of *priority*. For example, if wholes are ontologically dependent on their parts, but the latter in turn are not ontologically dependent on the former, one may say that parts are ontologically prior to wholes. The phrase 'logical priority' usually refers to priority of one of the three varieties to be discussed here.

Epistemic dependence. To say that the facts in some class *B* are epistemically dependent on the facts in some other class *A* is to say this: one cannot know any fact in *B* unless one knows some fact in *A* that serves as one's evidence for the fact in *B*. For example, it might be held that to know any fact about one's physical environment (e.g., that there is a fire in the stove), one must know (as evidence) some facts about the character of one's own sensory experience (e.g., that one is feeling warm and seeing flames). This would be to maintain that facts about the physical world are epistemically dependent on facts about sensory experience. If one held in addition that the dependence is not reciprocal – that one can know facts about one's sensory experience without knowing as evidence any facts about the physical world – one would be maintaining that the former facts are epistemically prior to the latter facts. Other plausible (though sometimes disputed) examples of epistemic priority are the following: facts about the behavior of others are epistemically prior to facts about their mental states; facts about observable objects are epistemically prior to facts about the invisible particles postulated by physics; and singular facts (e.g., this crow is black) are epistemically prior to general facts (e.g., all crows are black).

Is there a class of facts on which all others epistemically depend and that depend on no further facts in turn – a bottom story in the edifice of knowledge? Some foundationalists say yes, positing a level of basic or foundational facts that are epistemically prior to all others. Empiricists are usually foundationalists who maintain that the basic level consists of facts about immediate sensory experience. Coherentists deny the need for a privileged stratum of facts to ground the knowledge of all others; in effect, they deny that any facts are epistemically prior to any others. Instead, all facts are on a par, and each is known in virtue of the way in which it fits in with all the rest.

Sometimes it appears that two propositions or classes of them each epistemically depend on the other in a vicious way – to know *A*, you must first know *B*, and to know *B*, you must first know *A*. Whenever this is genuinely the case, we are in a skeptical predicament and cannot know either proposition. For example, Descartes believed that he could not be assured of the reliability of his own cognitions until he knew that God exists and is not a deceiver; yet how could he ever come to know anything about God except by relying on his own cognitions? This is the famous problem of the Cartesian circle. Another example is the problem of induction as set forth by Hume: to know that induction is a legitimate mode of inference, one would first have to know that the future will resemble the past; but since the latter fact is establishable only by induction, one could know it only if one already knew that induction is legitimate. Solutions to these problems must show that contrary to first appearances, there is a way of knowing one of the problematic propositions independently of the other.

Conceptual dependence. To say that *B*'s are conceptually dependent on *A*'s means that to understand what a *B* is, you must understand what an *A* is, or that the concept of a *B* can be explained or understood only through the concept of an *A*. For example, it could plausibly be claimed that the concept *uncle* can be understood only in terms of the concept *male*. Empiricists typically maintain that we understand what an external thing like a tree or a table is only by knowing what experiences it would induce in us, so that the concepts we apply to physical things depend on the concepts we apply to our experiences. They typically also maintain that this dependence is not reciprocal, so that experiential concepts are conceptually prior to physical concepts.

Some empiricists argue from the thesis of conceptual priority just cited to the corresponding thesis of epistemic priority – that facts about experiences are epistemically prior to facts about external objects. Turning the tables, some foes of empiricism maintain that the conceptual priority is the other way about: that we can describe and understand what kind of experience we are undergoing only by specifying what kind of object typically causes it ('It's a smell like that of pine mulch'). Sometimes they offer this as a reason for denying that facts about experiences are epistemically prior to facts about physical objects. Both sides in this dispute assume that a relation of conceptual priority in one direction excludes a relation of epistemic priority in the opposite direction. But why couldn't it be the case *both* that facts about experiences are epistemically prior to facts about physical objects *and* that concepts of physical objects are conceptually prior to concepts of experiences? How the various kinds of priority and dependence are connected (e.g., whether conceptual priority implies epistemic priority) is a matter in need of further study.

Ontological dependence. To say that entities of one sort (the *B*'s) are ontologically dependent on entities of another sort (the *A*'s) means this: no *B* can exist unless some *A* exists; i.e., it is logically or metaphysically necessary that if any *B* exists, some *A* also exists. Ontological dependence may be either specific (the existence of any *B* depending on the existence of a particular *A*) or generic (the existence of any *B* depending merely on the existence of some *A* or other). If *B*'s are ontologically dependent on *A*'s, but not conversely, we may say that *A*'s are ontologically prior to *B*'s. The traditional notion of substance is often defined in terms of ontological priority – substances can exist without other things, as Aristotle said, but the others cannot exist without them.

Leibniz believed that composite entities are ontologically dependent on simple (i.e., partless) entities – that any composite object exists only because it has certain simple elements that are arranged in a certain way. Berkeley, J. S. Mill, and other phenomenalists believed that physical objects are ontologically dependent on sensory experiences – that the existence of a table or a tree consists in the occurrence of sensory experiences in certain orderly patterns. Spinoza believed that all finite beings are ontologically dependent on God and that God is ontologically dependent on nothing further; thus God, being ontologically prior to everything else, is in Spinoza's view the only substance.

Sometimes there are disputes about the direction in which a relationship of ontological priority runs. Some philosophers hold that extension-less points are prior to extended solids, others that solids are prior to points; some say that things are prior to events, others that events are prior to things. In the face of such disagreement, still other philosophers (such as Goodman) have suggested that nothing is inherently or absolutely prior to anything else: *A*'s may be prior to *B*'s in one conceptual scheme, *B*'s to *A*'s in another, and there may be no saying which scheme is correct. Whether relationships of priority hold absolutely or only relative to conceptual schemes is one issue dividing realists and antirealists.

depiction, pictorial representation, also sometimes called "iconic representation." Linguistic representation is conventional: it is only by virtue of a convention that the word 'cats' refers to cats. A picture of a cat, however, seems to refer to cats by other than conventional means; for viewers can correctly interpret pictures without special training, whereas people need special training to learn languages. Though some philosophers, such as Goodman (*Languages of Art*), deny that depiction involves a non-conventional element, most are concerned to give an account of what this non-conventional element consists in. Some hold that it consists in resemblance: pictures refer to their objects partly by resembling them. Objections to this are that anything resembles anything else to some degree; and that resemblance is a symmetric and reflexive relation, whereas depiction is not. Other philosophers avoid direct appeal to resemblance: Richard Wollheim (*Painting as an Art*) argues that depiction holds by virtue of the intentional deployment of the natural human capacity to see objects in marked surfaces; and Kendall Walton (*Mimesis as Make-Believe*) argues that depiction holds by virtue of objects serving as props in reasonably rich and vivid visual games of make-believe. **See also** MIMESIS, PEIRCE. Derrida, Jacques (1930–2004), French philosopher, author of deconstructionism, and leading figure in the postmodern movement. Postmodern thought seeks to move beyond modernism by revealing inconsistencies or aporias within the Western European tradition from Descartes to the present. These aporias are largely associated with 'onto-theology', a term coined by Heidegger to characterize a manner of thinking about being and truth that ultimately grounds itself in a conception of divinity. Deconstruction is the methodology of revelation: it typically involves seeking out binary oppositions defined interdependently by mutual exclusion, such as good and evil or true and false, which function as founding terms for modern thought. The onto-theological metaphysics underlying modernism is a metaphysics of presence: to be is to be present, finally to be absolutely present to the absolute, i.e. to the divinity whose own being is conceived as presence to itself, as the coincidence of being and knowing in the Being that knows all things and knows itself as the reason for the being of all that is. Divinity thus functions as the measure of truth. The aporia here, revealed by deconstruction, is that this modernist measure of truth cannot meet its own measure: the coincidence of what is and what is known is an impossibility for finite intellects.

Major influences on Derrida include Hegel, Freud, Heidegger, Sartre, Saussure, and structuralist thinkers such as Lévi-Strauss, but it was his early critique of Husserl, in *Introduction à "L'Origine de la géometrie" de Husserl* (1962), that gained him recognition as a critic of the phenomenological tradition and set the conceptual framework for his later work. Derrida sought to demonstrate that the origin of geometry, conceived by Husserl as the guiding paradigm for Western thought, was a supratemporal ideal of perfect knowing that serves as the goal of human knowledge. Thus the origin of geometry is inseparable from its end or *telos*, a thought that Derrida later generalizes in his deconstruction of the notion of origin as such. He argues that this ideal cannot be realized in time, hence cannot be grounded in lived experience, hence cannot meet the "principle of principles" Husserl designated as the prime criterion for phenomenology, the principle that all knowing must ground itself in consciousness of an object that is coincidentally conscious of itself. This revelation of the aporia at the core of phenomenology in particular and Western thought in general was not yet labeled as a deconstruction, but it established the formal structure that guided Derrida's later deconstructive revelations of the metaphysics of presence underlying the modernism in which Western thought culminates.

Descartes, René (1596–1650), French philosopher and mathematician, a founder of the "modern age," and perhaps the most important figure in the intellectual revolution of the seventeenth century in which the traditional systems of understanding based on Aristotle were challenged and, ultimately, overthrown. His conception of philosophy was all-embracing: it encompassed mathematics and the physical sciences as well as psychology and ethics, and it was based on what he claimed to be absolutely firm and reliable metaphysical foundations. His approach to the problems of knowledge, certainty, and the nature of the human mind played a major part in shaping the subsequent development of philosophy.

Life and works. Descartes was born in a small town near Tours that now bears his name. He was brought up by his maternal grandmother (his mother having died soon after his birth), and at the age of ten he was sent to the recently founded Jesuit college of La Flèche in Anjou, where he remained as a boarding pupil for nine years. At La Flèche he studied classical literature and traditional classics-based subjects such as history and rhetoric as well as natural philosophy (based on the Aristotelian system) and theology. He later wrote of La Flèche that he considered it "one of the best schools in Europe," but that, as regards the philosophy he had learned there, he saw that "despite being cultivated for many centuries by the best minds, it contained no point which was not disputed and hence doubtful."

At age twenty-two (having taken a law degree at Poitiers), Descartes set out on a series of travels in Europe, "resolving," as he later put it, "to seek no knowledge other than that which could be found either in myself or the great book of the world." The most important influence of this early period was Descartes's friendship with the Dutchman Isaac Beeckman, who awakened his lifelong interest in mathematics – a science in which he discerned precision and certainty of the kind that truly merited the title of *scientia* (Descartes's term for genuine systematic knowledge based on reliable principles). A considerable portion of Descartes's energies as a young man was devoted to pure mathematics: his essay *Geometry* (published in 1637) incorporated results discovered during the 1620s. But he also saw mathematics as the key to making progress in the applied sciences; his earliest work, the *Compendium Musicae*, written in 1618 and dedicated to Beeckman, applied quantitative principles to the study of musical harmony and dissonance. More generally, Descartes saw mathematics as a kind of paradigm for all human understanding: "those long chains composed of very simple and easy reasonings, which geometers customarily use to arrive at their most difficult demonstrations, gave me occasion to suppose that all the things which fall within the scope of human knowledge are interconnected in the same way" (*Discourse on the Method*, Part II).

In the course of his travels, Descartes found himself closeted, on November 10, 1619, in a "stove-heated room" in a town in southern Germany, where after a day of intense meditation, he had a series of vivid dreams that convinced him of his mission to found a new scientific and philosophical system. After returning to Paris for a time, he emigrated to Holland in 1628, where he was to live (though with frequent changes of address) for most of the rest of his life. By 1633 he had ready a treatise on cosmology and physics, *Le Monde;* but he cautiously withdrew the work from publication when he heard of the condemnation of Galileo by the Inquisition for rejecting (as Descartes himself did) the traditional geocentric theory of the universe. But in 1637 Descartes released for publication, in French, a sample of his scientific work: three essays, entitled the *Optics, Meteorology*, and *Geometry*. Prefaced to that selection was an autobiographical introduction entitled *Discourse on the Method of rightly conducting one's reason and reaching the truth in the sciences*. This work, which includes discussion of a number of scientific issues such as the circulation of the blood, contains (in Part IV) a summary of Descartes's views on knowledge, certainty, and the metaphysical foundations of science. Criticisms of his arguments here led Descartes to compose his philosophical masterpiece, the *Meditations on First Philosophy*, published in Latin in 1641 – a dramatic account of the voyage of discovery from universal doubt to certainty of one's own existence, and the subsequent struggle to establish the existence of God, the nature and existence of the external world, and the relation between mind and body. The *Meditations* aroused enormous interest among Descartes's contemporaries, and six sets of objections by celebrated philosophers and theologians (including Mersenne, Hobbes, Arnauld, and Gassendi) were published in the same volume as the first edition (a seventh set, by the Jesuit Pierre Bourdin, was included in the second edition of 1642).

A few years later, Descartes published, in Latin, a mammoth compendium of his metaphysical and scientific views, the *Principles of Philosophy*, which he hoped would become a university textbook to rival the standard texts based on Aristotle. In the later 1640s, Descartes became interested in questions of ethics and psychology, partly as a result of acute questions about the implications of his system raised by Princess Elizabeth of Bohemia in a long and fruitful correspondence. The fruits of this interest were published in 1649 in a lengthy French treatise entitled *The Passions of the Soul*. The same year, Descartes accepted (after much hesitation) an invitation to go to Stockholm to give philosophical instruction to Queen Christina of Sweden. He was required to provide tutorials at the royal palace at five o'clock in the morning, and the strain of this break in his habits (he had maintained the lifelong custom of lying in bed late into the morning) led to his catching pneumonia. He died just short of his fifty-fourth birthday.

The Cartesian system. In a celebrated simile, Descartes described the whole of philosophy as like a tree: the roots are metaphysics, the trunk physics, and the branches are the various particular sciences, including mechanics, medicine, and morals. The analogy captures at least three important features of the Cartesian system. The first is its insistence on the essential unity of knowledge, which contrasts strongly with the Aristotelian conception of the sciences as a series of separate disciplines, each with its own methods and standards of precision. The sciences, as Descartes put it in an early notebook, are all "linked together" in a sequence that is in principle as simple and straightforward as the series of numbers. The second point conveyed by the tree simile is the utility of philosophy for ordinary living: the tree is valued for its fruits, and these are gathered, Descartes points out, "not from the roots or the trunk but from the ends of the branches" – the practical sciences. Descartes frequently stresses that his principal motivation is not abstract theorizing for its own sake: in place of the "speculative philosophy taught in the Schools," we can and should achieve knowledge that is "useful in life" and that will one day make us "masters and possessors of nature." Third, the likening of metaphysics or "first philosophy" to the roots of the tree nicely captures the Cartesian belief in what has come to be known as foundationalism – the view that knowledge must be constructed from the bottom up, and that nothing can be taken as established until we have gone back to first principles.

Doubt and the foundations of belief. In Descartes's central work of metaphysics, the *Meditations*, he begins his construction project by observing that many of the preconceived opinions he has accepted since childhood have turned out to be unreliable; so it is necessary, "once in a lifetime" to "demolish everything and start again, right from the foundations." Descartes proceeds, in other words, by applying what is sometimes called his method of doubt, which is explained in the earlier *Discourse on the Method:* "Since I now wished to devote myself solely to the search for truth, I thought it necessary to . . . reject as if absolutely false everything in which one could imagine the least doubt, in order to see if I was left believing anything that was entirely indubitable." In the *Meditations* we find this method applied to produce a systematic critique of previous beliefs, as follows. Anything based on the senses is potentially suspect, since "I have found by experience that the senses sometimes deceive, and it is prudent never to trust completely those who have deceived us even once." Even such seemingly straightforward judgments as "I am sitting here by the fire" may be false, since there is no guarantee that my present experience is not a dream. The *dream argument* (as it has come to be called) leaves intact the truths of mathematics, since "whether I am awake or asleep two and three make five"; but Descartes now proceeds to introduce an even more radical argument for doubt based on the following dilemma. If there is an omnipotent God, he could presumably cause me to go wrong every time I count two and three; if, on the other hand, there is no God, then I owe my origins not to a powerful and intelligent creator, but to some random series of imperfect causes, and in this case there is even less reason to suppose that my basic intuitions about mathematics are reliable.

By the end of the First Meditation, Descartes finds himself in a morass of wholesale doubt, which he dramatizes by introducing an imaginary demon "of the utmost power and cunning" who is systematically deceiving him in every possible way. Everything I believe in – "the sky, the earth and all external things" – might be illusions that the demon has devised in order to trick me. Yet this very extremity of doubt, when pushed as far as it will go, yields the first indubitable truth in the Cartesian quest for knowledge – the existence of the thinking subject. "Let the demon deceive me as much as he may, he can never bring it about that I am nothing, so long as I think I am something. . . . I am, I exist, is certain, as often as it is put forward by me or conceived in the mind." Elsewhere, Descartes expresses this *cogito* argument in the famous phrase "*Cogito ergo sum*" ("I am thinking, therefore I exist").

Having established his own existence, Descartes proceeds in the Third Meditation to make an inventory of the ideas he finds within him, among which he identifies the idea of a supremely perfect being. In a much criticized causal argument he reasons that the representational content (or "objective reality") of this idea is so great that it cannot have originated from inside his own (imperfect) mind, but must have been planted in him by an actual perfect being – God. The importance of God in the Cartesian system can scarcely be overstressed. Once the deity's existence is established, Descartes can proceed to reinstate his belief in the world around him: since God is perfect, and hence would not systematically deceive, the strong propensity he has given us to believe that many of our ideas come from external objects must, in general, be sound; and hence the external world exists (Sixth Meditation). More important still, Descartes uses the deity to set up a reliable method for the pursuit of truth. Human beings, since they are finite and imperfect, often go wrong; in particular, the data supplied by the senses is often, as Descartes puts it, "obscure and confused." But each of us can nonetheless avoid error, provided we remember to withhold judgment in such doubtful cases and confine ourselves to the "clear and distinct" perceptions of the pure intellect. A reliable intellect was God's gift to man, and if we use it with the greatest possible care, we can be sure of avoiding error (Fourth Meditation).

In this central part of his philosophy, Descartes follows in a long tradition going back to Augustine (with its ultimate roots in Plato) that in the first place is skeptical about the evidence of the senses as against the more reliable abstract perceptions of the intellect, and in the second place sees such intellectual knowledge as a kind of illumination derived from a higher source than man's own mind. Descartes frequently uses the ancient metaphor of the "natural light" or "light of reason" to convey this notion that the fundamental intuitions of the intellect are inherently reliable. The label 'rationalist', which is often applied to Descartes in this connection, can be misleading, since he certainly does not rely on reason *alone:* in the development of his scientific theories he allows a considerable role to empirical observation in the testing of hypotheses and in the understanding of the mechanisms of nature (his "vortex theory" of planetary revolutions is based on observations of the behavior of whirlpools).

What is true, nonetheless, is that the fundamental building blocks of Cartesian science are the innate ideas (chiefly those of mathematics) whose reliability Descartes takes as guaranteed by their having been implanted in the mind by God. But this in turn gives rise to a major problem for the Cartesian system, which was first underlined by some of Descartes's contemporaries (notably Mersenne and Arnauld) and which has come to be known as the *Cartesian circle*. If the reliability of the clear and distinct perceptions of the intellect depends on our knowledge of God, then how can that knowledge be established in the first place? If the answer is that we can prove God's existence from premises that we clearly and distinctly perceive, then this seems circular; for how are we entitled, at this stage, to assume that our clear and distinct perceptions are reliable? Descartes's attempts to deal with this problem are not entirely satisfactory, but his general answer seems to be that there are some propositions that are so simple and transparent that, so long as we focus on them, we can be sure of their truth even without a divine guarantee.

Cartesian science and dualism. The scientific system that Descartes had worked on before he wrote the *Meditations* and that he elaborated in his later work, the *Principles of Philosophy*, attempts wherever possible to reduce natural phenomena to the quantitative descriptions of arithmetic and geometry: "my consideration of matter in corporeal things," he says in the *Principles*, "involves absolutely nothing apart from divisions, shapes and motions." This connects with his metaphysical commitment to relying only on clear and distinct ideas. In place of the elaborate apparatus of the Scholastics, with its plethora of "substantial forms" and "real qualities," Descartes proposes to mathematicize science. The material world is simply an indefinite series of variations in the shape, size, and motion of the single, simple, homogeneous matter that he terms *res extensa* ("extended substance"). Under this category he includes all physical and biological events, even complex animal behavior, which he regards as simply the result of purely mechanical processes (for non-human animals as mechanical automata, see *Discourse*, Part V).

But there is one class of phenomena that cannot, on Descartes's view, be handled in this way, namely conscious experience. Thought, he frequently asserts, is completely alien to, and incompatible with, extension: it occupies no space, is unextended and indivisible. Hence Descartes puts forward a dualistic theory of substance: in addition to the *res extensa* that makes up the material universe, there is *res cogitans*, or thinking substance, which is entirely independent of matter. And each conscious individual is a unique thinking substance: "This 'I' – that is, the soul, by which I am what I am, is entirely distinct from the body, and would not fail to be what it is even if the body did not exist."

Descartes's arguments for the incorporeality of the soul were challenged by his contemporaries and have been heavily criticized by subsequent commentators. In the *Discourse* and the Second Meditation, he lays great stress on his ability to form a conception of himself as an existing subject, while at the same time doubting the existence of any physical thing; but this, as the critics pointed out, seems inadequate to establish the conclusion that he is a *res cogitans* – a being whose whole essence consists simply in thought. I may be able to imagine myself without a body, but this hardly proves that I could in reality exist without one (see further the Synopsis to the *Meditations*). A further problem is that our everyday experience testifies to the fact that we are not incorporeal beings, but very much creatures of flesh and blood. "Nature teaches me by the sensations of pain, hunger, thirst and so on," Descartes admits in the Sixth Meditation, "that I am not merely present in my body as a sailor is present in a ship, but that I am very closely joined and as it were intermingled with it." Yet how can an incorporeal soul interact with the body in this way? In his later writings, Descartes speaks of the "union of soul and body" as a "primitive notion" (see letters to Elizabeth of May 21 and June 28, 1643); by this he seems to have meant that, just as there are properties (such as length) that belong to body alone, and properties (such as understanding) that belong to mind alone, so there are items such as sensations that are irreducibly psychophysical, and that belong to me insofar as I am an *embodied* consciousness. The explanation of such psychophysical events was the task Descartes set himself in his last work, *The Passions of the Soul;* here he developed his theory that the pineal gland in the brain was the "seat of the soul," where data from the senses were received (via the nervous system) and where bodily movements were initiated. But despite the wealth of physiological detail Descartes provides, the central philosophical problems associated with his dualistic account of humans as hybrid entities made up of physical body and immaterial soul are, by common consent, not properly sorted out.

Influence. Despite the philosophical difficulties that beset the Cartesian system, Descartes's vision of a unified understanding of reality has retained a powerful hold on scientists and philosophers ever since. His insistence that the path to progress in science lay in the direction of quantitative explanations has been substantially vindicated. His attempt to construct a system of knowledge by starting from the subjective awareness of the conscious self has been equally important, if only because so much of the epistemology of our own time has been a reaction against the autocentric perspective from which Descartes starts out. As for the Cartesian theory of the mind, it is probably fair to say that the dualistic approach is now widely regarded as raising more problems than it solves. But Descartes's insistence that the phenomena of conscious experience are recalcitrant to explanation in purely physical terms remains deeply influential, and the cluster of profound problems that he raised about the nature of the human mind and its relation to the material world are still very far from being adequately resolved.

descriptivism, the thesis that the meaning of any evaluative statement is purely descriptive or factual, i.e. determined, apart from its syntactical features, entirely by its truth conditions. Non-descriptivism (of which emotivism and prescriptivism are the main varieties) is the view that the meaning of full-blooded evaluative statements is such that they *necessarily* express the speaker's sentiments or commitments. Nonnaturalism, naturalism, and supernaturalism are descriptivist views about the nature of the properties to which the meaning rules refer. Descriptivism is related to cognitivism and moral realism. **See also EMOTIVISM, ETHICS.** B.W.H.

designator, rigid. See MEANING.

design plan, as introduced by Alvin Plantinga into epistemology and philosophy of religion, the function of a biological or other system that some intelligent agent (a designer) intended it to have. The term is also used by advocates of intelligent design and occasionally in standard philosophy of biology. For Plantinga, a belief has warrant only if it results from a properly functioning cognitive faculty: one functioning according to its design plan. For Plantinga and also for advocates of intelligent design, the "design plan" is something intended by an agent. The term is sometimes used by others, however, for the role a biological system serves within an organism even though that system is assumed to have resulted from a process of unguided chance plus natural selection; for example, one might speak of evolution as designing the heart to pump blood, with the design plan referring to the type of integrated system that allows this function. **See also DARWINISM, DIVINE ATTRIBUTES, INTELLIGENT**

DESIGN, PHILOSOPHY OF BIOLOGY, PHILOSOPHY OF RELIGION, PHILOSOPHY OF SCIENCE. R.Co.

desire, a motivational state of either of two kinds, one roughly appetitive, the other roughly volitive. Consider a hungry dieter. Because of hunger, a hungry dieter who refrains from eating desires (wants), in one sense, to eat but, because of trying to lose weight, does not desire (want) to eat in another sense. In the sense in which 'desires to eat' applies here, 'desire' denotes a psychological state closely related (but not identical) to appetite. In the sense in which it does not apply, it denotes a state closely related (but not identical) to an intention or volition. Intending entails desiring in the volitive but not the appetitive sense. Hunger entails having a desire to eat in the appetitive but not the volitive sense. In neither sense does desiring entail intending to eat or being hungry. An appetitive desire for something tends to cause a volitive desire for it, but that tendency is often counteracted by beliefs about what one ought to do. Volitive desire to do something tends to cause the action, but that tendency may be blocked by inability, competing desires, or ignorance of the necessary means.

The different states designated by 'desire' have much in common. They are propositional attitudes and "intentional" in Brentano's sense: we can, for instance, desire things that do not exist. For me to desire to play tennis is for me to desire that I myself play tennis. For me to desire a bowl of chili is for me to desire that I have a bowl. Different ways of having a bowl of chili (consuming, possessing) correspond to different ways of desiring a bowl. Desire in both senses is quantitative: we desire some things more than others. Moreover, we are typically introspectively aware of our desires. And like belief, desires in both senses are "dispositional" in the sense that they need not be occurrent.

Doing something for a reason entails having an appropriately related volitive desire. If one's reason for going to the store is to buy aspirin, one wants to buy aspirin (in the volitive sense, but not necessarily the appetitive). Acting on these reasons also depends on having appropriately related beliefs. Desires are states that combine with beliefs to motivate and produce action.

Desire is entailed by a variety of propositional attitudes. Thus being happy that something will happen, being optimistic that it will, or hoping that it will all entail desiring it to happen (at least volitively). Like belief, however, desire (in both senses) appears to be fundamental in not being definable in terms of other psychological states.

determinable, a general characteristic or property analogous to a genus except that while a property independent of a genus differentiates a species that falls under the genus, no such independent property differentiates a determinate that falls under the determinable. The color blue, e.g., is a determinate with respect of the determinable color: there is no property *F* independent of color such that a color is blue if and only if it is *F*. In contrast, there is a property, *having equal sides*, such that a rectangle is a square if and only if it has this property. *Square* is a properly differentiated species of the genus *rectangle*.

W. E. Johnson introduces the terms 'determinate' and 'determinable' in his *Logic*, Part I, Chapter 11. His account of this distinction does not closely resemble the current understanding sketched above. Johnson wants to explain the differences between the superficially similar 'Red is a color' and 'Plato is a man'. He concludes that the latter really predicates something, humanity, of Plato; while the former does not really predicate anything of red. Color is not really a property (or adjective, as Johnson puts it). The determinates red, blue, and yellow are grouped together not because of a property they have in common but because of the ways they differ from each other. Determinates under the same determinable are related to each other (and are thus comparable) in ways in which they are not related to determinates under other determinables. Determinates belonging to different determinables, such as color and shape, are incomparable.

'More determinate' is often used interchangeably with 'more specific'. Many philosophers, including Johnson, hold that the characters of things are absolutely determinate or specific. Spelling out what this claim means leads to another problem in analyzing the relation between determinate and determinable. By what principle can we exclude *red and round* as a determinate of *red* and *red* as a determinate of *red or round?*

See also **JOHNSON**, **PROPERTY**. D.H.S.

determinate. See DETERMINABLE.

determinism, the view that every event or state of affairs is brought about by antecedent events or states of affairs in accordance with universal causal laws that govern the world. Thus, the state of the world at any instant determines a unique future, and that knowledge of all the positions of things and the prevailing natural forces would permit an intelligence to predict the future state of the world with absolute precision. This view was advanced by Laplace in the early nineteenth century; he was inspired by Newton's success at integrating our physical knowledge of the world.

Contemporary determinists do not believe that Newtonian physics is the supreme theory. Some do not even believe that all theories will someday be integrated into a unified theory. They do believe that, for each event, no matter how precisely described, there is some theory or system of laws such that the occurrence of that event under that description is derivable from those laws together with information about the prior state of the system. Some determinists formulate the doctrine somewhat differently: (a) every event has a sufficient cause; (b) at any given time, given the past, only one future is possible; (c) given knowledge of all antecedent conditions and all laws of nature, an agent could predict at any given time the precise subsequent history of the universe. Thus, determinists deny the existence of chance, although they concede that our ignorance of the laws or all relevant antecedent conditions makes certain events unexpected and, therefore, apparently happen "by chance."

The term 'determinism' is also used in a more general way as the name for any metaphysical doctrine implying that there is only one possible history of the world. The doctrine described above is really *scientific* or *causal determinism*, for it grounds this implication on a general fact about the natural order, namely its governance by universal causal law. But there is also *theological determinism*, which holds that God determines everything that happens or that, since God has perfect knowledge about the universe, only the course of events that he knows will happen can happen. And there is *logical determinism*, which grounds the necessity of the historical order on the logical truth that all propositions, including ones about the future, are either true or false. Fatalism, the view that there are forces (e.g., the stars or the fates) that determine all outcomes independently of human efforts or wishes, is claimed by some to be a version of determinism. But others deny this on the ground that determinists do not reject the efficacy of human effort or desire; they simply believe that efforts and desires, which are sometimes effective, are themselves determined by antecedent factors (as in a causal chain of events).

Since determinism is a universal doctrine, it embraces human actions and choices. But if actions and choices are determined, then some conclude that free will is an illusion. For the action or choice is an inevitable product of antecedent factors that rendered alternatives impossible, even if the agent had deliberated about options. An omniscient agent could have predicted the action or choice beforehand. This conflict generates the problem of free will and determinism.

Dewey, John (1859–1952), American philosopher, social critic, and theorist of education. During an era when philosophy was becoming thoroughly professionalized, Dewey remained a public philosopher having a profound international influence on politics and education. His career began inauspiciously in his student days at the University of Vermont and then as a high school teacher before he went on to study philosophy at the newly formed Johns Hopkins University. There he studied with Peirce, G. S. Hall, and G. S. Morris, and was profoundly influenced by the version of Hegelian idealism propounded by Morris. After receiving his doctorate in 1884, Dewey moved to the University of Michigan, where he rejoined Morris, who had relocated there. At Michigan he had as a colleague the young social psychologist G. H. Mead, and during this period Dewey himself concentrated his writing in the general area of psychology. In 1894 he accepted an appointment as chair of the Department of Philosophy, Psychology, and Education at the University of Chicago, bringing Mead with him. At Chicago Dewey was instrumental in founding the famous laboratory school, and some of his most important writings on education grew out of his work in that experimental school. In 1904 he left Chicago for Columbia University, where he joined F. J. E. Woodbridge, founder of the *Journal of Philosophy*. He retired from Columbia in 1930 but remained active in both philosophy and public affairs until his death in 1952. Over his long career he was a prolific speaker and writer, as evidenced by a literary output of forty books and over seven hundred articles.

Philosophy. At the highest level of generality Dewey's philosophical orientation can be characterized as a kind of *naturalistic empiricism*, and the two most fundamental notions in his philosophy can be gleaned from the title of his most substantial book, *Experience and Nature* (1925). His concept of experience had its origin in his Hegelian background, but Dewey divested it of most of its speculative excesses. He clearly conceived of himself as an empiricist but was careful to distinguish his notion of experience both from that of the idealist tradition and from the empiricism of the classical British variety. The idealists had so stressed the cognitive dimension of experience that they overlooked the non-cognitive, whereas he saw the British variety as inappropriately atomistic and subjectivist. In contrast to these Dewey fashioned a notion of experience wherein action, enjoyment, and what he called "undergoing" were integrated and equally fundamental. The felt immediacy of experience (what he generally characterized as its aesthetic quality) was basic and irreducible. He then situated cognitive experience against this broader background as arising from and conditioned by this more basic experience. Cognitive experience was the result of inquiry, which was viewed as a process arising from a felt difficulty within our experience, proceeding through the stage of conceptual elaboration of possible resolutions, to a final reconstruction of the experience wherein the initial fragmented situation is transformed into a unified whole. Cognitive inquiry is this mediating process from experience to experience, and knowledge is what makes possible the final more integrated experience, which Dewey termed a "consummation."

On this view knowing is a kind of doing, and the criterion of knowledge is "warranted assertability." On the first point, Dewey felt that one of the cardinal errors of philosophy from Plato to the modern period was what he called "the spectator theory of knowledge." Knowledge had been viewed as a kind of passive recording of facts in the world and success was seen as a matter of the correspondence of our beliefs to these antecedent facts. To the contrary, Dewey viewed knowing as a constructive conceptual activity that anticipated and guided our adjustment to future experiential interactions with our environment. It was with this constructive and purposive view of thinking in mind that Dewey dubbed his general philosophical orientation instrumentalism. Concepts are instruments for dealing with our experienced world. The fundamental categories of knowledge are to be functionally understood, and the classical dualisms of philosophy (mind-body, means-end, fact-value) are ultimately to be overcome.

The purpose of knowing is to effect some alteration in the experiential situation, and for this purpose some cognitive proposals are more effective than others. This is the context in which "truth" is normally invoked, and in its stead Dewey proposed "warranted assertability." He eschewed the notion of truth (even in its less dangerous adjectival and adverbial forms, 'true' and 'truly') because he saw it as too suggestive of a static and finalized correspondence between two separate orders. Successful cognition was really a more dynamic matter of a present resolution of a problematic situation resulting in a reconstructed experience or consummation. "Warranted assertability" was the success characterization, having the appropriately normative connotation without the excess metaphysical baggage.

Dewey's notion of experience is intimately tied to his notion of nature. He did not conceive of nature as "the-world-as-it-would-be-independent-of-human-experience" but rather as a developing system of natural transactions admitting of a tripartite distinction between the physicochemical level, the psychophysical level, and the level of human experience with the understanding that this categorization was not to be construed as implying any sharp discontinuities. Experience itself, then, is one of the levels of transaction in nature and is not reducible to the other forms. The more austere, "scientific" representations of nature as, e.g., a purely mechanical system Dewey construed as merely useful conceptualizations for specific cognitive purposes. This enabled him to distinguish his "naturalism," which he saw as a kind of non-reductive empiricism, from "materialism," which he saw as a kind of reductive rationalism. Dewey and Santayana had an ongoing dialogue on precisely this point.

Dewey's view was also naturalistic to the degree that it advocated the universal scope of scientific method. Influenced in this regard by Peirce, he saw scientific method not as restricted to a specific sphere but simply as the way we ought to think. The structure of all reflective thought is future-oriented and involves a movement from the recognition and articulation of a felt difficulty, through the elaboration of hypotheses as possible resolutions of the difficulty, to the stage of verification or falsification. The specific sciences (physics, biology, psychology) investigate the different levels of transactions in nature, but the scientific manner of investigation is simply a generalized sophistication of the structure of common sense and has no intrinsic restriction.

Dewey construed nature as an organic unity not marked by any radical discontinuities that would require the introduction of non-natural categories or new methodological strategies. The sharp dualisms of mind and body, the individual and the social, the secular and the religious, and most importantly, fact and value, he viewed as conceptual constructs that have far outlived their usefulness. The inherited dualisms had to be overcome, particularly the one between fact and value inasmuch as it functioned to block the use of reason as the guide for human action. On his view people naturally have values as well as beliefs. Given human nature, there are certain activities and states of affairs that we naturally prize, enjoy, and value. The human problem is that these are not always easy to come by nor are they always compatible. We are forced to deal with the problem of what we really want and what we ought to pursue. Dewey advocated the extension of scientific method to these domains. The deliberative process culminating in a practical judgment is not unlike the deliberative process culminating in factual belief. Both kinds of judgment can be responsible or irresponsible, right or wrong. This deliberative sense of evaluation as a process presupposes the more basic sense of evaluation concerning those dimensions of human experience we prize and find fulfilling. Here too there is a dimension of appropriateness, one grounded in the kind of beings we are, where the 'we' includes our social history and development. On this issue Dewey had a very Greek view, albeit one transposed into a modern evolutionary perspective. Fundamental questions of value and human fulfillment ultimately bear on our conception of the human community, and this in turn leads him to the issues of democracy and education.

Society and education. The ideal social order for Dewey is a structure that allows maximum self-development of all individuals. It fosters the free exchange of ideas and decides on policies in a manner that acknowledges each person's capacity effectively to participate in and contribute to the direction of social life. The respect accorded to the dignity of each contributes to the common welfare of all. Dewey found the closest approximation to this ideal in democracy but he did not identify contemporary democracies with this ideal. He was not content to employ old forms of democracy to deal with new problems. Consistent with instrumentalism, he maintained that we should be constantly rethinking and reworking our democratic institutions in order to make them ever more responsive to changing times. This constant rethinking placed a considerable premium on intelligence, and this underscored the importance of education for democracy.

Dewey is probably best known for his views on education, but the centrality of his theory of education to his overall philosophy is not always appreciated. The fundamental aim of education for him is not to convey information but to develop critical methods of thought. Education is future-oriented and the future is uncertain; hence, it is paramount to develop those habits of mind that enable us adequately to assess new situations and to formulate strategies for dealing with the problematic dimensions of them. This is not to suggest that we should turn our backs on the past, because what we as a people have already learned provides our only guide for future activity. But the past is not to be valued for its own sake but for its role in developing and guiding those critical capacities that will enable us to deal with our ever-changing world effectively and responsibly.

With the advent of the analytic tradition as the dominant style of philosophizing in America, Dewey's thought fell out of favor. About the only arenas in which it continued to flourish were schools of education. However, with the recent revival of a general pragmatic orientation in the persons of Quine, Putnam, and Rorty, among others, the spirit of Dewey's philosophy is frequently invoked. Holism, anti-foundationalism, contextualism, functionalism, the blurring of the lines between science and philosophy and between the theoretical and the practical – all central themes in Dewey's philosophy – have become fashionable. Neo-pragmatism is a contemporary catchphrase. Dewey is, however, more frequently invoked than read, and even the Dewey that is invoked is a truncated version of the historical figure who constructed a comprehensive philosophical vision.

dharma, in Hinduism and especially in the early literature of the Vedas, a cosmic rule giving things their nature or essence or, in the human context, a set of duties and rules to be performed or followed to maintain social order, promote general well-being, and be righteous. Pursuit of dharma was considered one of the four fundamental pursuits of life, the three others being those of wealth (*artha*), pleasure (*kama*), and spiritual liberation (*moksha*). In the Bhagavad Gita, dharma was given wide currency as *svadharma*, meaning one's assigned duties based on one's nature and abilities rather than on birth. The Hindu lawgiver Manu (who probably lived between the third century B.C. and the first century A.D.) codified the dharmic duties based on a fourfold order of society and provided concrete guidance to people in discharging their social obligations based on their roles and stations in life. Even though Manu, like the Gita, held that one's duties and obligations should fit one's nature rather than be determined by birth, the dharma-oriented Hindu society was eventually characterized by a rigid caste structure and a limited role for women. **See also** BHAGAVAD GITA. D.K.C.

Dharmakīrti (seventh century A.D.), Indian Yogācāra Buddhist philosopher and logician. His works include *Pramānavārttika* ("Explanation of the Touchstones"), a major work in logic and epistemology; and *Nyāyabindu*, an introduction to his views. In *Santānāntara-siddhi* ("Establishment of the Existence of Other Minds") he defends his perceptual idealism against the charge of solipsism, claiming that he may as legitimately use the argument from analogy for the existence of others (drawing inferences from apparently intelligent behaviors to intelligences that cause them) as his perceptual realist opponents. He criticized Nyāya theistic arguments. He exercised a strong influence on later Indian work in logic. K.E.Y.

d'Holbach, Paul-Henri-Dietrich, Baron (1723–89), French philosopher, a leading materialist and prolific contributor to the *Encyclopedia*. He was born in the Rhenish Palatinate, settled in France at an early age, and read law at Leiden. After inheriting an uncle's wealth and title, he became a solicitor at the Paris "Parlement" and a regular host of philosophical dinners attended by the Encyclopedists and visitors of renown (Gibbon, Hume, Smith, Sterne, Priestley, Beccaria, Franklin). Knowledgeable in chemistry and mineralogy and fluent in several languages, he translated German scientific works and English anti-Christian pamphlets into French.

Basically, d'Holbach was a synthetic thinker, powerful though not original, who systematized and radicalized Diderot's naturalism. Also drawing on Hobbes, Spinoza, Locke, Hume, Buffon, Helvétius, and La Mettrie, his treatises were so irreligious and anticlerical that they were published abroad anonymously or pseudonymously: *Christianity Unveiled* (1756), *The Sacred Contagion* (1768), *Critical History of Jesus* (1770), *The Social System* (1773), and *Universal Moral* (1776). His masterpiece, the *System of Nature* (1770), a "Lucretian" compendium of eighteenth-century materialism, even shocked Voltaire. D'Holbach derived everything from matter and motion, and upheld universal necessity. The self-sustaining laws of nature are normative. Material reality is therefore contrasted to metaphysical delusion, self-interest to alienation, and earthly happiness to otherworldly optimism. More vindictive than Toland's, d'Holbach's unmitigated critique of Christianity anticipated Feuerbach, Strauss, Marx, and Nietzsche. He discredited supernatural revelation, theism, deism, and pantheism as mythological, censured Christian virtues as unnatural, branded piety as fanatical, and stigmatized clerical ignorance, immorality, and despotism. Assuming that science liberates man from religious hegemony, he advocated sensory and experimental knowledge. Believing that society and education form man, he unfolded a mechanistic anthropology, a eudaimonistic morality, and a secular, utilitarian social and political program.

diagonalization. See DIAGONAL PROCEDURE.

diagonal procedure, a method, originated by Cantor, for showing that there are infinite sets that cannot be put in one-to-one correspondence with the set of natural numbers (i.e., enumerated). For example, the method can be used to show that the set of real numbers x in the interval $0 < x \leq 1$ is not enumerable. Suppose $x_0, x_1, x_2, \dots$ were such an enumeration (x_0 is the real correlated with 0; x_1, the real correlated with 1; and so on). Then consider the list formed by replacing each real in the enumeration with the unique non-terminating decimal fraction representing it:

$$\begin{array}{lllll} \cdot & x_{00} & x_{01} & x_{02} & \dots \\ \cdot & x_{10} & x_{11} & x_{12} & \dots \\ \cdot & x_{20} & x_{21} & x_{22} & \dots \\ & & \dots & & \end{array}$$

(The first decimal fraction represents x_0; the second, x_1; and so on.) By diagonalization we select the decimal fraction shown by the arrows:

$$\begin{tikzcd} \cdot & x_{00} \arrow[dr] & x_{01} & x_{02} & \dots \\ \cdot & x_{10} & x_{11} \arrow[dr] & x_{12} & \dots \\ \cdot & x_{20} & x_{21} & x_{22} & \dots \\ & & \dots & & \end{tikzcd}$$

and change each digit x_{mn}, taking care to avoid a terminating decimal. This fraction

$$\cdot \quad x^*_{00}\ x^*_{11}\ x^*_{22} \dots$$

is not on our list. For it differs from the first in the tenths place, from the second in the hundredths place, and from the third in the thousandths place, and so on. Thus the real it represents is not in the supposed enumeration. This contradicts the original assumption.

The idea can be put more elegantly. Let f be any function such that, for each natural number n, $f(n)$ is a set of natural numbers. Then there is a set S of natural numbers such that $n \in S \equiv n \notin f(n)$. It is obvious that, for each n, $f(n) \neq S$.

dialectic, an argumentative exchange involving contradiction or a technique or method connected with such exchanges. The word's origin is the Greek *dialegein*, 'to argue' or 'converse'; in Aristotle and others, this often has the sense 'argue for a conclusion', 'establish by argument'. By Plato's time, if not earlier, it had acquired a technical sense: a form of argumentation through question and answer. The adjective *dialektikos*, 'dialectical', would mean 'concerned with *dialegein*' or (of persons) 'skilled in *dialegein*'; the feminine *dialektike* is then 'the art of *dialegein*'. Aristotle says that Zeno of Elea invented dialectic. He apparently had in mind Zeno's paradoxical arguments against motion and multiplicity, which Aristotle saw as dialectical because they rested on premises his adversaries conceded and deduced contradictory consequences from them. A first definition of dialectical argument might then be: 'argument conducted by question and answer, resting on an opponent's concessions, and aiming at refuting the opponent by deriving contradictory consequences'. This roughly fits the style of argument Socrates is shown engaging in by Plato. So construed, dialectic is primarily an art of refutation. Plato, however, came to apply 'dialectic' to the method by which philosophers attain knowledge of Forms. His understanding of that method appears to vary from one dialogue to another and is difficult to interpret. In *Republic* VI–VII, dialectic is a method that somehow establishes "non-hypothetical" conclusions; in the *Sophist*, it is a method of discovering definitions by successive divisions of genera into their species.

Aristotle's concept of dialectical argument comes closer to Socrates and Zeno: it proceeds by question and answer, normally aims at refutation, and cannot scientifically or philosophically establish anything. Aristotle differentiates dialectical arguments from *demonstration* (*apodeixis*), or scientific arguments, on the basis of their premises: demonstrations must have "true and primary" premises, dialectical arguments premises that are "apparent," "reputable," or "accepted" (these are alternative, and disputed, renderings of the term *endoxos*). However, dialectical arguments must be valid, unlike *eristic* or *sophistical* arguments. The *Topics*, which Aristotle says is the first art of dialectic, is organized as a handbook for dialectical debates; Book VIII clearly presupposes a rule-directed, formalized style of disputation presumably practiced in the Academy.

This use of 'dialectic' reappears in the early Middle Ages in Europe, though as Aristotle's works became better known after the twelfth century, dialectic was increasingly associated with the formalized disputations practiced in the universities (recalling once again the formalized practice presupposed by Aristotle's *Topics*). In his *Critique of Pure Reason*, Kant declared that the ancient meaning of 'dialectic' was 'the logic of illusion' and proposed a "Transcendental Dialectic" that analyzed the "antinomies" (deductions of contradictory conclusions) to which pure reason is inevitably led when it extends beyond its proper sphere. This concept was further developed by Fichte and Schelling into a triadic notion of *thesis*, opposing *antithesis*, and resultant *synthesis*. Hegel transformed the notion of contradiction from a logical to a metaphysical one, making dialectic into a theory not simply of arguments but of historical processes within the development of "spirit"; Marx transformed this still further by replacing 'spirit' with 'matter'.

dialecticians. See SCHOOL OF NAMES.

dialetheism, a view promoted (in its modern form) chiefly by Graham Priest, according to which there are *dialetheias*. A *dialetheia* is a proposition, *A*, such that both it and its negation, ~*A*, are simultaneously true. Assuming that a proposition is false if and only if its negation is true, dialetheism affirms that there are *some* true contradictions and thus rejects the principle of contradiction. Relatedly, since, given the principle of explosion, a contradiction trivializes a system inasmuch as any proposition can be derived within it, dialetheists reject explosion, which they do in order to avoid trivialization. Dialetheism is often motivated by paradoxes of self-reference. **See also** EXPLOSION, PRINCIPLE OF CONTRADICTION, RUSSELL, TYPE THEORY. F.St.

diallelon (from ancient Greek *di allelon*, 'through one another'), a circular definition. A definition is circular provided either the *definiendum* occurs in the *definiens*, as in 'Law is a lawful command', or a first term is defined by means of a second term, which in turn is defined by the first term, as in 'Law is the expressed wish of a ruler, and a ruler is one who establishes laws'.

A *diallelus* is a circular argument: an attempt to establish a conclusion by a premise that cannot be known unless the conclusion is known in the first place. Descartes, e.g., argued: I clearly and distinctly perceive that God exists, and what I clearly and distinctly perceive is true. Therefore, God exists. To justify the premise that clear and distinct perceptions are true, however, he appealed to his knowledge of God's existence.

diallelus. See DIALLELON.

dialogism. See BAKHTIN.

dianoia, Greek term for the faculty of thought, specifically of drawing conclusions from assumptions and of constructing and following arguments. The term may also designate the thought that results from using this faculty. We would use *dianoia* to construct a mathematical proof; in contrast, a being – if there is such a being it would be a god – that could simply intuit the truth of the theorem would use the faculty of intellectual intuition, *noûs*. In contrast with *noûs, dianoia* is the distinctly human faculty of reason. Plato uses *noûs* and *dianoia* to designate, respectively, the highest and second levels of the faculties represented on the divided line (*Republic* 511d–e). **See also** PLATO. E.C.H.

dici de omni et nullo. See DICTUM DE OMNI ET NULLO.

dictum. See ABELARD, COMPLEXE SIGNIFICABILE.

dictum de omni et nullo, also *dici de omni et nullo* (Latin, 'said of all and none'), two principles that medieval logicians took to underlie all valid syllogisms. *Dictum de omni* applies most naturally to universal affirmative propositions, stating that in such a proposition, whatever falls under the subject term also falls under the predicate term. Thus, in 'Every whale is a mammal', whatever is included under 'whale' is included under 'mammal'. *Dictum de nullo* applies to universal negative propositions, such as 'No whale is a lizard', stating that whatever falls under the subject term does not fall under the predicate. **See also** SYLLOGISM. W.E.M.

Diderot, Denis (1713–84), French philosopher, Encyclopedist, dramatist, novelist, and art critic, a champion of Enlightenment values. He is known primarily as general editor of the *Encyclopedia* (1747–73), an analytical and interpretive compendium of eighteenth-century science and technology. A friend of Rousseau and Condillac, Diderot translated Shaftesbury's *Inquiry Concerning Virtue* (1745) into French. Revealing Lucretian affinities (*Philosophical Thoughts*, 1746), he assailed Christianity in *The Skeptics' Walk* (1747) and argued for a materialistic and evolutionary universe (*Letter on the Blind*, 1749); this led to a short imprisonment.

Diderot wrote mediocre bourgeois comedies; some bleak fiction (*The Nun*, 1760); and two satirical dialogues, *Rameau's Nephew* (1767) and *Jacques the Fatalist* (1765–84), his masterpieces. He innovatively theorized on drama (*Discourse on Dramatic Poetry*, 1758) and elevated art criticism to a literary genre (*Salons* in Grimm's *Literary Correspondence*). At Catherine II's invitation, Diderot visited Saint Petersburg in 1773 and planned the creation of a Russian university.

Promoting science, especially biology and chemistry, Diderot unfolded a philosophy of nature inclined toward monism. His works include physiological investigations, *Letter on the Deaf and Dumb* (1751) and *Elements of Physiology* (1774–80); a sensationalistic epistemology, *On the Interpretation of Nature* (1745); an aesthetic, *Essays on Painting* (1765); a materialistic philosophy of science, *D'Alembert's Dream* (1769); an anthropology, *Supplement to the Voyage of Bougainville* (1772); and an anti-behavioristic *Refutation of Helvétius' Work "On Man"* (1773–80).

différance, a French coinage deployed by Derrida in *De la grammatologie* (1967), where he defines it as "an economic concept designating the production of differing/deferring." *Différance* is polysemic, but its key function is to name the prime condition for the functioning of all language and thought: differing, the differentiation of signs from each other that allows us to differentiate things from each other. Deferring is the process by which signs refer to each other, thus constituting the self-reference essential to language, without ever capturing the being or presence that is the transcendent entity toward which it is aimed. Without the concepts or idealities generated by the iteration of signs, we could never identify a dog as a dog, could not perceive a dog (or any other thing) as such. Perception presupposes language, which, in turn, presupposes the ideality generated by the repetition of signs. Thus there can be no perceptual origin for language; language depends upon an "original repetition," a deliberate oxymoron that Derrida employs to signal the impossibility of conceiving an origin of language from within the linguistic framework in which we find ourselves. *Différance* is the condition for language, and language is the condition for experience: whatever meaning we may find in the world is attributed to the differing/deferring play of signifiers.

The notion of *différance* and the correlative thesis that meaning is language-dependent have been appropriated by radical thinkers in the attempt to demonstrate that political inequalities are grounded in nothing other than the conventions of sign systems governing differing cultures.

differentia. See DEFINITION, TOPICS.

dignity, a moral worth or status usually attributed to human persons. Persons are said to have dignity as well as to express it. Persons are typically thought to have (1) "human dignity" (an intrinsic moral worth, a basic moral status, or both, which is had equally by all persons); and (2) a "sense of dignity" (an awareness of one's dignity inclining toward the expression of one's dignity and the avoidance of humiliation). Persons can lack a sense of dignity without consequent loss of their human dignity.

In Kant's influential account of the equal dignity of all persons, human dignity is grounded in the capacity for practical rationality, especially the capacity for autonomous self-legislation under the categorical imperative. Kant holds that dignity contrasts with price and that there is nothing – not pleasure nor communal welfare nor other good consequences – for which it is morally acceptable to sacrifice human dignity. Kant's categorical rejection of the use of persons as mere means suggests a now-common link between the possession of human dignity and human rights (see, e.g., the United Nations'

Universal Declaration of Human Rights). One now widespread discussion of dignity concerns "dying with dignity" and the right to conditions conducive thereto.

dilemma, an argument or argument form in which one of the premises is a disjunction. *Constructive dilemmas* take the form 'If *A* and *B*, if *C* then *D*, *A* or *C*; therefore *B* or *D*' and are instances of *modus ponens* in the special case where *A* is *C* and *B* is *D*; *destructive dilemmas* are of the form 'If *A* then *B*, if *C* then *D*, not-*B* or not-*D*; therefore not-*A* or not-*C*' and are likewise instances of *modus tollens* in that special case. A dilemma having a false disjunctive premise is commonly known as a *false dilemma*. **See also** MORAL DILEMMA. G.F.S.

dilemma, moral. See MORAL DILEMMA.

Dilthey, Wilhelm (1833–1911), German philosopher and historian whose main project was to establish the conditions of historical knowledge, much as Kant's *Critique of Pure Reason* had for our knowledge of nature. He studied theology, history, and philosophy at Heidelberg and Berlin and in 1882 accepted the chair earlier held by Hegel at the University of Berlin.

Dilthey's first attempt at a critique of historical reason is found in the *Introduction to the Human Sciences* (1883), the last in the *Formation of the Historical World in the Human Sciences* (1910). He is also a recognized contributor to hermeneutics, literary criticism, and worldview theory. His *Life of Schleiermacher* and essays on the Renaissance, Enlightenment, and Hegel are models of *Geistesgeschichte*, in which philosophical ideas are analyzed in relation to their social and cultural milieu.

Dilthey holds that life is the ultimate nexus of reality behind which we cannot go. Life is viewed, not primarily in biological terms as in Nietzsche and Bergson, but as the historical totality of human experience. The basic categories whereby we reflect on life provide the background for the epistemological categories of the sciences. According to Dilthey, Aristotle's category of acting and suffering is rooted in prescientific experience, which is then explicated as the category of efficacy or influence (*Wirkung*) in the human sciences and as the category of cause (*Ursache*) in the natural sciences. Our understanding of influence in the human sciences is less removed from the full reality of life than are the causal explanations arrived at in the natural sciences. To this extent the human sciences can claim a priority over the natural sciences. Whereas we have direct access to the real elements of the historical world (psychophysical human beings), the elements of the natural world are merely hypothetical entities such as atoms. The natural sciences deal with outer experiences, while the human sciences are based on inner experience. Inner experience is reflexive and implicitly self-aware, but need not be introspective or explicitly self-conscious. In fact, we often have inner experiences of the same objects that outer experience is about. An outer experience of an object focuses on its physical properties; an inner experience of it on our felt responses to it. A lived experience (*Erlebnis*) of it includes both.

The distinction between the natural and the human sciences is also related to the methodological difference between explanation and understanding. The natural sciences seek causal explanations of nature – connecting the discrete representations of outer experience through hypothetical generalizations. The human sciences aim at an understanding (*Verstehen*) that articulates the typical structures of life given in lived experience. Finding lived experience to be inherently connected and meaningful, Dilthey opposed traditional atomistic and associationist psychologies and developed a descriptive psychology that Husserl recognized as anticipating phenomenological psychology.

In *Ideas* (1894) Dilthey argued that descriptive psychology could provide a neutral foundation for the other human sciences, but in his later hermeneutical writings, which influenced Heidegger and Gadamer, he rejected the possibility of a foundational discipline. In the *Formation*, he asserted that all the human sciences are interpretive and mutually dependent. Hermeneutically conceived, understanding is a process of interpreting the "objectifications of life," the external expressions of human experience and activity. The understanding of others is mediated by these common objectifications and not immediately available through empathy (*Einfühlung*). Moreover, to fully understand myself I must interpret the expressions of my life just as I interpret the expressions of others.

Whereas the natural sciences aim at ever broader generalizations, the human sciences place equal weight on understanding individuality and universality. Dilthey regarded individuals as points of intersection of the social and cultural systems in which they participate. Any psychological contribution to understanding human life must be integrated into this more public framework. Although universal laws of history are rejected, particular human sciences can establish uniformities limited to specific social and cultural systems.

In a set of sketches (1911) supplementing the *Formation*, Dilthey further developed the categories of life in relation to the human sciences. After analyzing formal categories such as the part-whole relation shared by all the sciences, he distinguished the real categories of the human sciences from those of the natural sciences. The most important human science categories are value, purpose, and meaning, but they by no means exhaust the concepts needed to reflect on the ultimate sense of our existence. Such reflection receives full expression in a worldview (*Weltanschauung*), such as the worldviews developed in religion, art, and philosophy. A worldview constitutes an overall perspective on life that sums up what we know about the world, how we evaluate it emotionally, and how we respond to it volitionally. Since Dilthey distinguished three exclusive and recurrent types of worldview – naturalism (e.g., Democritus, Hume), the idealism of freedom (e.g., Socrates, Kant), and objective idealism (e.g., Parmenides, Hegel) – he is often regarded as a relativist. But Dilthey thought that both the natural and the human sciences could in their separate ways attain objective truth through a proper sense of method. Metaphysical formulations of worldviews are relative only because they attempt an impossible synthesis of all truth.

diminished capacity, a legal defense against criminal liability that exists in two distinct forms: (1) the *mens rea* variant, in which a defendant uses evidence of mental abnormality to cast doubt on the prosecution's assertion that, at the time of the crime, the defendant possessed the mental state criteria, the *mens rea*, required by the legal definition of the offense charged; and (2) the partial responsibility variant, in which defendants use evidence of mental abnormality to support a claim that, even if their mental state satisfied the *mens rea* criteria for the offense, their responsibility for the crime is diminished and thus they should be convicted of a lesser crime and/or a lesser sentence should be imposed. The mental abnormality may be produced by mental disorder, intoxication, trauma, or other causes. The *mens rea* variant is not a distinct excuse: a defendant is simply arguing that the prosecution cannot prove the definitional, mental state criteria for the crime. Partial responsibility is an excuse, but unlike the similar, complete excuse of legal insanity, partial responsibility does not produce total acquittal; rather, a defendant's claim is for reduced punishment. A defendant may raise either or both variants of diminished capacity and the insanity defense in the same case.

For example, a common definition of first-degree murder requires the prosecution to prove that a defendant intended to kill and did so after premeditation. A defendant charged with this crime might raise both variants as follows. To deny the allegation of premeditation, a defendant might claim that the killing occurred instantaneously in response to a "command hallucination." If believed, a defendant cannot be convicted of *premeditated* homicide, but can be convicted of the lesser crime of second-degree murder, which typically requires only intent. And even a defendant who killed intentionally and premeditatedly might claim partial responsibility because the psychotic mental state rendered the agent's reasons for action non-culpably irrational. In this case, either the degree of crime might be reduced by operation of the partial excuse, rather than by negation of definitional *mens rea*, or a defendant might be convicted of first-degree murder but given a lesser penalty.

In the United States the *mens rea* variant exists in about half the jurisdictions, although its scope is usually limited, primarily to avoid a defendant's being acquitted and freed if mental abnormality negated *all* the definitional mental state criteria of the crime charged. In a widely criticized opinion, *Clark v. Arizona* (2006), the U.S. Supreme Court upheld the constitutionality of excluding all evidence of mental abnormality introduced for the purpose of negating *mens rea*. In English law, the *mens rea* variant exists but is limited by the type of evidence usable to support it. No American jurisdiction has adopted a distinct, straightforward partial responsibility variant, but various analogous doctrines and procedures are widely accepted. For example, partial responsibility grounds both the doctrine that intentional killing should be reduced from murder to voluntary manslaughter if a defendant acted "in the heat of passion" upon legally adequate provocation, and a sentencing judge's discretion to award a decreased sentence based on a defendant's mental abnormality. In addition to such partial responsibility analogues, England, Wales, and Scotland have directly adopted the partial responsibility variant, termed 'diminished responsibility', but it applies only to prosecutions for murder. Diminished responsibility reduces a conviction to a lesser crime, such as manslaughter or culpable homicide, for behavior that would otherwise constitute murder.

direction of fit, a metaphor that derives from a story in Anscombe's *Intention* (1957) about a detective who follows a shopper around town making a list of the things that the shopper buys. As Anscombe notes, whereas the detective's list has to match the way the world is (each of the things the shopper buys must be on the detective's list), the shopper's list is such that the world has to fit with it (each of the things on the list are things that he must buy). The metaphor is now standardly used to describe the difference between kinds of speech act (assertions vs. commands) and mental states (beliefs vs. desires). For example, beliefs are said to have the world-to-mind direction of fit because it is in the nature of beliefs that their contents are supposed to match the world: false beliefs are to be abandoned. Desires are said to have the opposite mind-to-world direction of fit because it is in the nature of desires that the world is supposed to match their contents. This is so at least to the extent that the role of an unsatisfied desire that the world be a certain way is to prompt behavior aimed at making the world that way. **See also** ANSCOMBE, BELIEF, MOTIVATION. direct realism, the theory that perceiving is epistemically direct, unmediated by conscious or unconscious inference. Direct realism is distinguished, on the one hand, from indirect, or representative, realism, the view that perceptual awareness of material objects is mediated by an awareness of sensory representations, and, on the other hand, from forms of phenomenalism that identify material objects with states of mind. It might be thought that direct realism is incompatible with causal theories of perception. Such theories invoke causal chains leading from objects perceived (causes) to perceptual states of perceivers (effects). Since effects must be distinct from causes, the relation between an instance of perceiving and an object perceived, it would seem, cannot be direct. This, however, confuses *epistemic* directness with *causal* directness. A direct realist need only be committed to the former. In my perceiving a tomato to be red, the content of my perceptual awareness is the tomato's being red. I enter this state as a result of a complex causal process, perhaps. But my perception may be direct in the sense that it is unmediated by an awareness of a representational sensory state from which I am led to an awareness of the tomato. Perceptual error, and more particularly, hallucinations and illusions, are usually thought to pose special difficulties for direct realists. My hallucinating a red tomato, for instance, is not my being directly aware of a red tomato, since I may hallucinate the tomato even when none is present. Perhaps, then, my hallucinating a red tomato is partly a matter of my being directly aware of a round, red sensory representation. And if my awareness in this case is indistinguishable from my perception of an actual red tomato, why not suppose that I am aware of a sensory representation in the veridical case as well? A direct realist may respond by denying that hallucinations are in fact indistinguishable from veridical perceivings or by calling into question the claim that, if sensory representations are required to explain hallucinations, they need be postulated in the veridical case. **See also** PERCEPTION, PHENOMENALISM. direct sense. See OBLIQUE CONTEXT.

disagreement, narrowly understood, one person believing a proposition while another believes its negation; broadly understood, two or more people having different levels of credence in the same proposition. Disagreement is often explainable by either evidential or cognitive asymmetries between the parties to the dispute, such as when one person has more evidence or better eyesight than another. When rationality requires the adjustment of beliefs in such cases, however, the fact that there is disagreement drops out of the explanation of this adjustment. The explanatory work is instead done by the difference in the familiarity with the relevant evidence or the asymmetry in cognitive capacities. In order to determine whether *disagreement* itself has significance, there should not be any relevant epistemic asymmetries between the disputants that would allow them to explain away the occurrence of the disagreement: they should take one another to be *epistemic peers* relative to the disputed question. The central question, then, is, what does rationality require when there is disagreement between those who regard one another as epistemic peers?

There are two standard ways of understanding epistemic peerhood. The first is this: A and B are epistemic peers relative to the question whether *p* when A and B are (roughly) evidential and cognitive equals regarding this question. Evidential and cognitive equality are, in turn, fleshed out as follows. *Evidential equality* occurs where A and B are evidential equals relative to the question whether *p* when A and B are equally familiar with the evidence and arguments that bear on the question whether *p*. *Cognitive equality* occurs where, relative to the question whether *p*, A and B are equally competent, intelligent, and fair-minded in their assessment of the evidence and arguments that bear on the question.

On this understanding of epistemic peers, then, the question becomes what rationality requires when there is disagreement between those who regard one another as evidential and cognitive equals. There is an immediate problem with this understanding of epistemic peerhood. Many of the most important disagreements – those that seem to fall within the scope of this topic – are such that the disputants would not regard one another as peers in this sense. For instance, if a theist appeals to her connection with God via prayer as at least part of the basis for her theistic belief, then she would clearly not regard the atheist as her evidential equal regarding this question, since such a connection is presumably inaccessible to someone who does not pray. Because this sort of disagreement at least appears relevant to the debate, evidential equality and cognitive equality are often eschewed as the best criteria for epistemic peerhood.

An alternative characterization of epistemic peerhood is offered in the following: A and B are epistemic peers relative to the question whether *p* when, conditional on disagreeing about this question, A and B are equally likely to be mistaken. This characterization of peerhood is compatible both with evidential equality in fact failing to obtain and with the parties to the dispute believing that this is so. Thus, it does not suffer from the problem facing the view above. For instance, A may see a car accident occur, and B may accept testimony from the driver that it took place. A and B may not be evidential equals regarding the occurrence of the accident, since A's evidence is firsthand and B's secondhand, but they may nonetheless think that, conditional on disagreeing about it, they are equally likely to be mistaken. This is plausible when they regard A's vision and the driver's testimony as equally reliable regarding the occurrence of the accident. The revised version of the central question, then, is: What does rationality require when there is disagreement between those who think that, conditional on disagreeing regarding the question whether *p*, they are equally likely to be mistaken?

Two main answers are offered. On the one hand, there is the *conciliatory* (or *conformist*) view, where disagreement itself is regarded as possessing enormous epistemic significance. On this view, unless one has a reason that is independent of the disagreement itself to prefer one's own belief, one cannot continue to rationally hold a belief when one is faced with an epistemic peer who explicitly believes its negation. Thus, according to conciliationism, there cannot be reasonable disagreement among epistemic peers because equal weight should be given to one's own beliefs and to those held by one's epistemic peers, thereby requiring significant belief revision in the face of peer disagreement. For those who understand the debate in terms of an all-or-nothing model of belief, disagreement with an epistemic peer regarding a given question requires that both parties to the dispute *withhold* belief relative to this question. For those who instead frame the issues in terms of degrees of belief, disagreement with an epistemic peer regarding a given question requires *splitting the difference* in the degrees of their respective beliefs. But regardless of the details, conciliationists all agree that when epistemic peers disagree, substantial adjustment is required in their respective beliefs.

A problem with the conciliationist view is that it seems to deliver the wrong result in cases of extreme disagreement. For instance, suppose that A and B are eating lunch together at a restaurant with a pitcher of water in the middle of the table, inches from each of them and in plain sight. Suppose further, however, that when A asks B to pass the pitcher, B denies its existence. Finally, suppose that prior to this disagreement, neither A nor B had any reason to think that the other was evidentially or cognitively deficient in any way, and they both sincerely avowed their respective conflicting beliefs. Now, consider the situation in question from A's perspective. It clearly seems to A that there is a pitcher of water on the table – indeed, suppose that minutes earlier, A poured and drank a glass of water from it. Moreover, A has never hallucinated an object, A has not been drinking or taking any drugs, A has her contact lenses in, A has ample evidence of her eyesight functioning reliably, and A knows all of this to be true of herself. How, then, should A rationally respond to B's claim that there is not a pitcher of water on the table? Despite the fact that, up to now, A has had good reason to regard B as an epistemic peer, it seems clearly rational for A to continue to believe just as strongly that the pitcher is on the table. For given the extraordinarily high degree of justified confidence with which A holds the belief about the pitcher of water, B's disagreement seems best taken as evidence that something has gone awry with B, either evidentially or cognitively. In other words, A seems justified in concluding that B is no longer an epistemic peer, even if she was prior to the disagreement in question. The upshot of these considerations, then, is that conciliationism apparently delivers the wrong response in such cases. A further problem facing this view is that it seems to require that its very proponents withhold belief on whether conciliationism is true. In particular, since there is disagreement about the correct account in the epistemology of disagreement itself, it looks as though conciliationists must split the difference in the degree of their belief with those who endorse the opposing view and hence cannot rationally believe their own account.

By contrast, the *steadfast* (or *nonconformist*) view entails that disagreement can be wholly without epistemic significance. On this view, one can continue to rationally hold a belief despite an epistemic peer's explicitly believing its negation, even when one has no reason independent of the disagreement in question to prefer one's own belief. Thus, according to proponents of the steadfast view, there can be reasonable disagreement among epistemic peers because both parties may be rational in holding their conflicting beliefs. There are different explanations for this. One is the *egocentric response*, where a subject is justified in giving her belief extra weight in the face of peer disagreement because the belief in question is *hers*. Another is the *correct reasoning response*, where a subject is justified in giving her belief extra weight in the face of peer disagreement because the belief in question is *in fact the product of correct reasoning*. But despite the differences in these explanations, proponents of the steadfast view all agree that the mere fact that there is disagreement with one's epistemic peer does not rationally mandate any sort of belief revision from either party to the dispute.

The problem with the steadfast view, however, is that it seems to deliver the wrong result in some ordinary cases. For instance, suppose that A and B are dining with three other friends and they all agree to leave a 20 percent tip and to evenly split the cost of the bill. A and B rightly regard one another as peers where calculations are concerned – they frequently dine together and consistently arrive at the same figure when dividing up the amount owed. After the bill arrives and each has a clear look at it, A asserts with confidence that she has carefully calculated in her head that each owes $43, while B asserts with the same degree of confidence that she has carefully calculated in her head that each owes $45. In such a case, it seems quite clear that rationality requires substantial belief revision on both parts until they are able to recheck their calculations. For, barring any unusual circumstances, both A and B should recognize the likelihood that they could be wrong and that there is no reason to prefer their own belief to that of the other. Thus, the steadfast view seems to deliver the wrong response in this sort of case.

In response to these problems, views have emerged in the epistemology of disagreement that are properly regarded as neither conciliationist nor steadfast in character. The first is the *justificationist view*, according to which the appropriate epistemic response in cases of peer disagreement is determined by the justificatory status of the relevant beliefs, including the beliefs one has about the proper functioning of one's own cognitive capacities. These latter beliefs are called *personal information*, which can be used to break the symmetry between two otherwise epistemic peers. On the justificationist view, if one's belief is highly justified before the dispute, then no doxastic revision may be required in the face of peer disagreement, because the presence of personal information may break the symmetry between the epistemic peers, whereas substantial revision may be needed if the belief is initially poorly justified. The second is the *total evidence view*, where the total evidence possessed by the parties to the debate determines whether doxastic revision is required. This includes both the lower-order evidence initially possessed by the parties to the debate and the higher-order evidence provided by the peer disagreement itself.

Most discussions in the epistemology of disagreement focus on disagreements between epistemic peers as such, but many epistemologists have turned their attention specifically to these sorts of disagreements within philosophy. It has been argued, for instance, that disagreements can be easily resolved in some domains, while consensus often emerges over time in others. But disagreements in philosophy fall into neither of these groups, and thus philosophical beliefs held in the face of peer disagreement are typically not justified. It has also been claimed that the following three propositions are individually defensible yet jointly inconsistent: (1) reliability is a necessary condition for epistemic justification; (2) on contested matters in philosophy, one's beliefs are not reliably formed; (3) some of these beliefs are epistemically justified. In response, it is argued that while learning of an instance of peer disagreement provides one with a reason against one's philosophical belief, this reason can sometimes be discounted on the grounds that one's peer is unreliable when it comes to the philosophical truth in question.

disbelief, with respect to a proposition, either believing it to be false or believing its negation to be true. Since the notion of disbelief contains the notion of belief, we must have a grip on the latter in order to understand the former. Propositional belief takes propositions as its objects. Examples are your belief that DNA is responsible for the heritability of traits, and Newton's belief that God occasionally adjusts the orbits of the planets. Believing that *p* (a proposition) is believing that *p* is true, or, as the medievals said, it is (when occurrent) thinking that *p* with assent.

Given this account of belief, disbelief is the belief that not-*p*. Modern cosmologists disbelieve the very proposition that Newton believed; i.e., they believe that that proposition is false. Disbelief, then, is a form of belief, believing that not-*p*. Disbelief must be distinguished from non-belief as well as from suspension of judgment. Someone is in a state of non-belief with respect to *p* when she neither believes that *p* nor disbelieves that *p*. This state can obtain in two ways. Medievals were in a state of non-belief with respect to the proposition that DNA is responsible for the heritability of traits, as they never even entertained that proposition. But one can also be in a state of non-belief with respect to a proposition that one *does* entertain. Many people have entertained the proposition that there is extraterrestrial life, without coming to a resolution as to whether it is true; they neither believe nor disbelieve that proposition. This second way of being in the state of non-belief is often called suspension of judgment; for the first way no special term exists.

Related to disbelief is the notion of unbelief as used in theology. A person S is deemed to be in a state of unbelief when (1) S disbelieves one or more theological propositions in a privileged set that has among its members such propositions as that Christ is God incarnate (there is no agreement about which propositions are in the set); (2) S has never even entertained any of the propositions of the set (and does not believe any proposition self-evidently entailing them). Someone who suspends judgment on these propositions qualifies as an agnostic, but not as an unbeliever.

disembodiment, the immaterial state of existence of a person who previously had a body. Disembodiment is thus to be distinguished from non-embodiment or immateriality. God and angels, if they exist, are non-embodied, or immaterial. By contrast, if human beings continue to exist after their bodies die, then they are disembodied. As this example suggests, disembodiment is typically discussed in the context of immortality or survival of death. It presupposes a view according to which persons are souls or some sort of immaterial entity that is capable of existing apart from a body. Whether it is possible for a person to become disembodied is a matter of controversy. Most philosophers who believe that this is possible assume that a disembodied person is conscious, but it is not obvious that this should be the case. **See also** **PERSONAL IDENTITY, PHILOSOPHY OF MIND, PLATO, SURVIVAL.** E.R.W.

disjoint. See SET THEORY.

disjunction. See DISJUNCTIVE PROPOSITION, SYLLOGISM.

disjunction elimination. (1) The argument form '*A* or *B*, if *A* then *C*, if *B* then *C*; therefore, *C*' and arguments of this form. (2) The rule of inference that permits one to infer *C* from a disjunction together with derivations of *C* from each of the disjuncts separately. This is also known as the *rule of disjunctive elimination* or ∨*-elimination*. **See also** **DISJUNCTIVE PROPOSITION.** G.F.S.

disjunction introduction. (1) The argument form '*A* (or *B*); therefore, *A* or *B*' and arguments of this form. (2) The rule of inference that permits one to infer a disjunction from either of its disjuncts. This is also known as the *rule of addition* or ∨*-introduction*. **See also** **DISJUNCTIVE PROPOSITION.** G.F.S.

disjunctive normal form. See NORMAL FORM.

disjunctive proposition, a proposition whose main propositional operator (main connective) is the disjunction operator, i.e. the logical operator that represents 'and/or'. Thus, '(*P*-and/or-*Q*)-and-*R*' is not a disjunctive proposition because its main connective is the conjunction operation, but '*P*-and/or-(*Q*-and-*R*)' is disjunctive. R.W.B.

disjunctive syllogism. See SYLLOGISM.

disjunctivism, in philosophy of perception, a metaphysical thesis about perceptual experience that denies a specific mental element common to veridical perception and subjectively indistinguishable misperceptions, referential illusions, and hallucinations. Imagine looking at a red ball in good light. Light bounces off the ball and enters your visual system, which produces your visual experience. Normally, you will have a veridical perceptual experience of a red ball. Now imagine that, unbeknownst to you, a highly skilled and powerful scientist removes the ball from the room, but simultaneously preserves the very same effects on your retina. Your visual system then processes the stimulation in the same way. Now you no longer *see* the ball, but you will not notice the change. It will still seem to you as if you see a red ball. You are having a referential illusion, for there is no object to which your experience refers. Is there a specific mental element in common between the two cases? Sense-datum theorists hold that in both cases you are immediately aware of the same thing: a red-round sense-datum. Representationalists hold that in both cases you represent the presence of a round red object of such a size and location. Both theorists postulate a specific mental element in common between the cases. Disjunctivists deny this: the perceptual experience is *either* a veridical perception *or* an illusion having no specific mental element in common with the veridical case.

Disjunctivists advance different views on the nature of the disjuncts. On a positive version, a veridical perception is a relation between the perceiver and the object perceived, such that the object is part of the nature of the perceptual experience, whereas a misperception, referential illusion, or hallucination involves a relation between the perceiver and an inner experience or a sense-datum, such that the inner experience or sense-datum is a part of the nature of the experience. Since outer physical objects and inner experiences or sense-data are very different kinds, the disjuncts would have no specific mental element in common. On a negative version, the second disjunct would be characterized negatively, as a state indistinguishable by the experience from a veridical perception. It should be noted that *epistemological disjunctivism* is neutral regarding perceptual disjunctivism. It denies that veridical perceptions, misperceptions, referential illusions, and hallucinations are equal in power to ground knowledge or justification.

disposition, a tendency of an object or system to act or react in characteristic ways in certain situations. Fragility, solubility, and radioactivity are typical physical dispositions; generosity and irritability are typical dispositions of persons. For behaviorism, functionalism, and some forms of materialism, mental events, such as the occurrence of an idea, and states, such as beliefs, are also dispositions. Hypothetical or conditional statements are implied by dispositional claims and capture their basic meaning: the glass would shatter if suitably struck; left undisturbed, a radium atom will probably decay in a certain time; etc. These are usually taken as subjunctive rather than material conditionals (to avoid problems like having to count as soluble anything not immersed in water). The characteristic mode of action or reaction – shattering, decaying, etc. – is termed the disposition's *manifestation* or *display*. But it need not be observable. Fragility is a *regular* or *universal* disposition; a suitably struck glass invariably shatters. Radioactivity is *variable* or *probabilistic;* radium may or may not decay in a certain situation. Dispositions may also be *multi-track* or *multiply manifested*, rather than *single-track* or *singly manifested:* like hardness or elasticity, they may have different manifestations in different situations.

In *The Concept of Mind* (1949) Ryle argued that there is nothing more to dispositional claims than their associated conditionals: dispositional properties are not *occurrent;* to possess a dispositional property is not to undergo any episode or occurrence, or to be in a particular state. (Coupled with a positivist rejection of unobservables, and a conception of mental episodes and states as dispositions, this supports the view of behaviorism that such episodes and states are nothing but dispositions to observable behavior.) By contrast, realism holds that dispositional talk is also about actual or occurrent properties or states, possibly unknown or unobservable. In particular, it is about the bases of dispositions in intrinsic properties or states: fragility is based in molecular structure, radioactivity in nuclear structure. A disposition's basis is viewed as at least partly the cause of its manifestation. Some philosophers hold that the bases are categorical, not dispositional (D. M. Armstrong, *A Materialist Theory of Mind*, 1968). Others, notably Popper, hold that all properties are dispositional.

distribution, the property of standing for every individual designated by a term. The Latin term *distributio* originated in the twelfth century; it was applied to terms as part of a theory of reference, and it may have simply indicated the property of a term prefixed by a universal quantifier. The term 'dog' in 'Every dog has his day' is distributed, because it supposedly refers to every dog. In contrast, the same term in 'A dog bit the mailman' is not distributed because it refers to only one dog. In time, the idea of distribution came to be used only as a heuristic device for determining the validity of categorical syllogisms: (1) every term that is distributed in a premise must be distributed in the conclusion; (2) the middle term must be distributed at least once. Most explanations of distribution in logic textbooks are perfunctory; and it is stipulated that the subject terms of universal propositions and the predicate terms of negative propositions are distributed. This is intuitive for A-propositions, e.g. 'All humans are mortal'; the property of being mortal is distributed over each human. The idea of distribution is not intuitive for, say, the predicate term of O-propositions. According to the doctrine, the sentence 'Some humans are not selfish' says in effect that if all the selfish things are compared with some select human (one that is not selfish), the relation of identity does not hold between that human and *any* of the selfish things. Notice that the idea of distribution is not mentioned in this explanation. The idea of distribution is currently disreputable, mostly because of the criticisms of Geach in *Reference and Generality* (1968) and its irrelevance to standard semantic theories.

The related term 'distributively' means 'in a manner designating every item in a group individually', and is used in contrast with 'collectively'. The sentence 'The rocks weighed 100 pounds' is ambiguous. If 'rocks' is taken distributively, then the sentence means that each rock weighed 100 pounds. If 'rocks' is taken collectively, then the sentence means that the total weight of the rocks was 100 pounds.

distributive justice. See JUSTICE.

distributive laws, the logical principles

$$A \wedge (B \vee C) \equiv (A \wedge B) \vee (A \vee C)$$

and

$$A \vee (B \wedge C) \equiv (A \vee B) \wedge (A \vee C).$$

Conjunction is thus said to distribute over disjunction and disjunction over conjunction. **See also** DE MORGAN'S LAWS. G.F.S.

distributively. See DISTRIBUTION.

divided line, one of three analogies (with the sun and cave) offered in Plato's *Republic* (VI, 509d–511e) as a partial explanation of the Good. Socrates divides a line into two unequal segments: the longer represents the intelligible world and the shorter the sensible world. Then each of the segments is divided in the same proportion. Socrates associates four mental states with the four resulting segments (beginning with the shortest): *eikasia*, illusion or the apprehension of images; *pistis*, belief in ordinary physical objects; *dianoia*, the sort of hypothetical reasoning engaged in by mathematicians; and *noesis*, rational ascent to the first principle of the Good by means of dialectic. **See also** PLATO, SOCRATES. W.J.P.

divine attributes, properties of God; especially, those properties that are essential and unique to God. Among properties traditionally taken to be attributes of God, omnipotence, omniscience, and omnibenevolence are naturally taken to mean having, respectively, power, knowledge, and moral goodness to the maximum degree. Here God is understood as an eternal (or everlasting) being of immense power, knowledge, and goodness, who is the creator and sustainer of the universe and is worthy of human worship.

Omnipotence is maximal power. Some philosophers, notably Descartes, have thought that omnipotence requires the ability to do absolutely anything, including the logically impossible. Most classical theists, however, understood omnipotence as involving vast powers, while nevertheless being subject to a range of limitations of ability, including the inability to do what is logically impossible, the inability to change the past or to do things incompatible with what has happened, and the inability to do things that cannot be done by a being who has other divine attributes, e.g. to sin or to lie.

Omniscience is unlimited knowledge. According to the most straightforward account, omniscience is knowledge of all true propositions. But there may be reasons for recognizing a limitation on the class of true propositions that a being must know in order to be omniscient. For example, if there are true propositions about the future, omniscience would then include foreknowledge. But some philosophers have thought that foreknowledge of human actions is incompatible with those actions being free. This has led some to deny that there are truths about the future and others to deny that such truths are knowable. In the latter case, omniscience might be taken to be knowledge of all *knowable* truths. Or if God is eternal and if there are certain tensed or temporally indexical propositions that can be known only by someone who is in time, then omniscience presumably does not extend to such propositions. It is a matter of controversy whether omniscience includes middle knowledge, i.e. knowledge of what an agent would do if other, counterfactual, conditions were to obtain. Since recent critics of middle knowledge (in contrast to Báñez and other sixteenth-century Dominican opponents of Molina) usually deny that the relevant counterfactual conditionals alleged to be the object of such knowledge are true, denying the possibility of middle knowledge need not restrict the class of true propositions a being must know in order to be omniscient. Finally, although the concept of omniscience might not itself constrain how an omniscient being acquires its knowledge, it is usually held that God's knowledge is neither inferential (i.e., derived from premises or evidence) nor dependent upon causal processes.

Omnibenevolence is, literally, complete desire for good; less strictly, perfect moral goodness. Traditionally it has been thought that God does not merely happen to be good but that he must be so and that he is unable to do what is wrong. According to the former claim, God is *essentially* good; according to the latter, he is *impeccable*. It is a matter of controversy whether God is perfectly good in virtue of complying with an external moral standard or whether he himself sets the standard for goodness.

Divine sovereignty is God's rule over all of creation. According to this doctrine, God did not merely create the world and then let it run on its own; he continues to govern it in complete detail according to his good plan. Sovereignty is thus related to divine providence. A difficult question is how to reconcile a robust view of God's control of the world with libertarian free will.

Aseity (or *perseity*) is complete independence. In a straightforward sense, God is not dependent on anyone or anything for his existence. According to stronger interpretation of aseity, God is completely independent of everything else, including his properties. This view supports a doctrine of divine simplicity according to which God is not distinct from his properties.

Simplicity is the property of having no parts of any kind. According to the doctrine of divine simplicity, not only does God not have spatial or temporal parts, but there is no distinction between God and his essence, between his various attributes (in him, omniscience and omnipotence, e.g., are identical), and between God and his attributes. Attributing simplicity to God was standard in medieval theology, but the doctrine has seemed to many contemporary philosophers to be baffling, if not incoherent.

See also DESCARTES, DIVINE FOREKNOWLEDGE, MIDDLE KNOWLEDGE, MOLINA, PHILOSOPHY OF RELIGION. E.R.W.

divine command ethics, an ethical theory according to which part or all of morality depends upon the will of God as promulgated by divine commands. This theory has an important place in the history of Christian ethics. Divine command theories are prominent in the Franciscan ethics developed by John Duns Scotus and William Ockham; they are also endorsed by disciples of Ockham such as d'Ailly, Gerson, and Gabriel Biel; both Luther and Calvin adopt divine command ethics; and in modern British thought, important divine command theorists include Locke, Berkeley, and Paley. Divine command theories are typically offered as accounts of the deontological part of morality, which consists of moral requirements (obligation), permissions (rightness), and prohibitions (wrongness). On a divine command conception, actions forbidden by God are morally wrong because they are thus forbidden, actions not forbidden by God are morally right because they are not thus forbidden, and actions commanded by God are morally obligatory because they are thus commanded.

Many Christians find divine command ethics attractive because the ethics of love advocated in the Gospels makes love the subject of a command. Matthew 22:37–40 records Jesus as saying that we are commanded to love God and our neighbor. According to Kierkegaard, there are two reasons to suppose that Christian love of neighbor must be an obligation imposed by divine command: first, only an obligatory love can be sufficiently extensive to embrace everyone, even one's enemies; second, only an obligatory love can be invulnerable to changes in its objects, a love that alters not when it alteration finds.

The chief objection to the theory is that dependence on divine commands would make morality unacceptably arbitrary. According to divine command ethics, murder would not be wrong if God did not exist or existed but failed to forbid it. Perhaps the strongest reply to this objection appeals to the doctrines of God's necessary existence and essential goodness. God could not fail to exist and be good, and so God could not fail to forbid murder. In short, divine commands are not arbitrary fiats.

divine command theory. See DIVINE COMMAND ETHICS, ETHICS.

divine foreknowledge, God's knowledge of the future. It appears to be a straightforward consequence of God's omniscience that he has knowledge of the future, for presumably omniscience includes knowledge of all truths and there are truths about the future. Moreover, divine foreknowledge seems to be required by orthodox religious commitment to divine prophecy and divine providence. In the former case, God could not reliably reveal what will happen if he does know what will happen. And in the latter case, it is difficult to see how God could have a plan for what happens without knowing what that will be. A problem arises, however, in that it has seemed to many that divine foreknowledge is incompatible with human free action. Some philosophers (notably Boethius) have reasoned as follows: If God knows that a person will do a certain action, then the person must perform that action, but if a person must perform an action, the person does not perform the action freely. So if God knows that a person will perform an action, the person does not perform the action freely. This reason for thinking that divine foreknowledge is incompatible with human free action commits a simple modal fallacy. What must be the case is the conditional that if God knows that a person will perform an action then the person will in fact perform the action. But what is required to derive the conclusion is the implausible claim that from the assumption that God knows that a person will perform an action it follows not simply that the person *will* perform the action but that the person *must* perform it. Perhaps other attempts to demonstrate the incompatibility, however, are not as easily dismissed. One response to the apparent dilemma is to say that there really are no such truths about the future, either none at all or none about events, like future free actions, that are not causally necessitated by present conditions. Another response is to concede that there are truths about the future but to deny that truths about future free actions are knowable. In this case omniscience may be understood as knowledge, not of all truths, but of all knowable truths. A third, and historically important, response is to hold that God is eternal and that from his perspective everything is present and thus not future. These responses implicitly agree that divine foreknowledge is incompatible with human freedom, but they provide different accounts of omniscience according to which it does not include foreknowledge, or, at any rate, not foreknowledge of future free actions. **See also** DIVINE ATTRIBUTES, FREE WILL PROBLEM, MIDDLE KNOWLEDGE, PHILOSOPHY OF RELIGION. domain, of a science, the class of individuals that constitute its subject matter. Zoology, number theory, and plane geometry have as their respective domains the class of animals, the class of natural numbers, and the class of plane figures. In *Posterior Analytics* 76b10, Aristotle observes that each science presupposes its domain, its basic concepts, and its basic principles. In modern formalizations of a science using a standard first-order formal language, the domain of the science is often, but not always, taken as the universe of the intended interpretation or intended model, i.e. as the range of values of the individual variables. **See also** AXIOMATIC METHOD, FORMALIZATION, FORMAL LOGIC, MODEL THEORY, ONTOLOGICAL COMMITMENT, UNIVERSE OF DISCOURSE, VARIABLE. Dong Zhongshu (Tung Chung-shu) (c.179–c.104 B.C.), Chinese philosopher, a Han scholar famous for his answers to questions by Emperor Wu, which were instrumental in making Confucianism the state doctrine in 136 B.C. He wrote *Chunqiu fanlu* ("Luxuriant Gems of the Spring and Autumn Annals"), in which he read moral messages from historical events recorded in the classics in such a way that they could be applied to future history. Dong's teachings were actually quite different from those of Confucius and Mencius. He believed that Heaven and the Way do not change, and he taught the so-called Three Bonds, according to which the ruler, the father, and the husband are to be the standards of the ruled, the son, and the wife. These added a conservative ring to Confucianism, so that the rulers were happy to use it in combination with Legalist practice to create a state Confucianism. He also incorporated many ideas from the yin-yang school in his philosophy. He believed that history goes in cycles, the five powers (wood, fire, earth, metal, water) succeed each other, and there is a strict correlation between natural affairs and human affairs. He saw natural disasters as warning signs for the rulers to cultivate virtues and not to abuse their powers. **See also** CONFUCIANISM, CONFUCIUS, MENCIUS. S.-h.L.

donkey sentences, sentences exemplified by 'Every man who owns a donkey beats it', 'If a man owns a donkey, he beats it', and similar forms, which have posed logical puzzles since medieval times but were noted more recently by Geach. At issue is the logical form of such sentences – specifically, the correct construal of the pronoun 'it' and the indefinite noun phrase 'a donkey'. Translations into predicate logic by the usual strategy of rendering the indefinite as existential quantification and the pronoun as a bound variable (cf. 'John owns a donkey and beats it' → $(\exists x)$ (x is a donkey & John owns x &

John beats *x*)) are either ill-formed or have the wrong truth conditions. With a universal quantifier, the logical form carries the controversial implication that every donkey-owning man beats every donkey he owns. Efforts to resolve these issues have spawned much significant research in logic and linguistic semantics. **See also** LOGICAL FORM. R.E.W.

doomsday argument, an argument (associated chiefly with the mathematician Brandon Carter and the philosopher John Leslie) purporting to show, by appeal to Bayes's theorem (and Bayes's rule), that whatever antecedent probability we may have assigned to the hypothesis that human life will end relatively soon is magnified, perhaps greatly, upon our learning (or noticing) that we are among the first few score thousands of millions of human beings to exist. See Leslie's *The End of the World: The Science and Ethics of Human Extinction* (1996).

The argument is based on an allegedly close analogy between the question of the probability of imminent human extinction given our ordinal location in the temporal swath of humanity and the fact that the reader's name being among the first few drawn randomly from an urn may greatly enhance for the reader the probability that the urn contains fairly few names rather than very many.

double effect, principle of. See PRINCIPLE OF DOUBLE EFFECT.

double negation. (1) The principle, also called the law of double negation, that every proposition is logically equivalent to its double negation. Thus, the proposition that Roger is a rabbit is equivalent to the proposition that Roger is not not a rabbit. The law holds in classical logic but not for certain non-classical concepts of negation. In intuitionist logic, for example, a proposition implies, but need not be implied by, its double negation. (2) The rule of inference, also called the rule of double negation, that permits one to infer the double negation of *A* from *A*, and vice versa. **See also** FORMAL LOGIC. G.F.S.

double negation, law of. See DOUBLE NEGATION.

double truth, the theory that a thing can be true in philosophy or according to reason while its opposite is true in theology or according to faith. It serves as a response to conflicts between reason and faith. For example, on one interpretation of Aristotle, there is only one rational human soul, whereas, according to Christian theology, there are many rational human souls. The theory of double truth was attributed to Averroes and to Latin Averroists such as Siger of Brabant and Boethius of Dacia by their opponents, but it is doubtful that they actually held it. Averroes seems to have held that a single truth is scientifically formulated in philosophy and allegorically expressed in theology. Latin Averroists apparently thought that philosophy concerns what would have been true by natural necessity absent special divine intervention, and theology deals with what is actually true by virtue of such intervention. On this view, there would have been only one rational human soul if God had not miraculously intervened to multiply what by nature could not be multiplied. No one clearly endorsed the view that rational human souls are both only one and also many in number. **See also** AVERROES, SIGER OF BRABANT. P.L.Q.

doxa. See DOXASTIC.

doxastic (from Greek *doxa*, 'belief'), of or pertaining to belief. A doxastic mental state, for instance, is or incorporates a belief. Doxastic states of mind are to be distinguished, on the one hand, from such non-doxastic states as desires, sensations, and emotions and, on the other hand, from subdoxastic states. By extension, a doxastic principle is a principle governing belief. A doxastic principle might set out conditions under which an agent's forming or abandoning a belief is justified (epistemically or otherwise). **See also** REASONS FOR BELIEF. J.F.H.

doxastic holism. See HOLISM.

doxastic voluntarism. See VOLUNTARISM.

doxographers, compilers of and commentators on the opinions of ancient Greek philosophers. 'Doxographers' is an English translation of the modern Latin term coined by Hermann Diels for the title of his work *Doxographi Graeci* (1879). Here Diels assembled a series of Greek texts in which the views of Greek philosophers from the archaic to the Hellenistic era are set out in a relatively schematic way. In a lengthy introduction, Diels reconstructed the history of the writing of these opinions, the doxography; this reconstruction is now a standard part of the historiography of ancient philosophy. The doxography itself is important both as a source of information for early Greek philosophy and also because later writers, ancient, medieval, and modern, often relied on it rather than primary materials. The crucial text for Diels's reconstruction was the book *Physical Opinions of the Philosophers* (*Placita Philosophorum*), traditionally ascribed to Plutarch but no longer thought to be by him. The work lists the views of various philosophers and schools under subject headings such as "What Is Nature?" and "On the Rainbow." Out of this work and others Diels reconstructed a *Collection of Opinions* that he ascribed to Aetius (A.D. c.100), a person mentioned by Theodoret (fifth century) as the author of such a work. Diels took Aetius's ultimate source to be Theophrastus, who wrote a more discursive *Physical Opinions*. Because Aetius mentions the views of Hellenistic philosophers writing after Theophrastus, Diels postulated an intermediate source, which he called the *Vetusta Placita* (c.100 B.C.). The most accessible doxographical material is in the *Lives and Opinions of Eminent Philosophers* by Diogenes Laertius (A.D. c.200), who is, however, mainly interested in biography. He arranges philosophers by schools and treats each school chronologically. I.M.

dravya, in Indian philosophies, substance. In Nyāya-Vaishesika all living and non-living things are substances, possessors of qualities (*gunas*), and causes of effects. Substances come in nine varieties: earth, air, fire, water, ether, time, space, minds, and bodies. For Jainism, there are six types of substances: the principles of motion and rest, space, time, minds, and bodies. Each (except time) is extended and each (except bodies) is immaterial. Viśistadvaita, claiming six sorts of substance, includes God as a substance, as does Dvaita, on which all other substances depend for existence. Typically, schools of Buddhism deny that there are any substances, holding that what appear to be such are only bundles of events or states. K.E.Y.

dravyasat (Sanskrit, 'existence as a thing' or, more loosely, 'primary existence'), a category used by Indian Buddhist scholars to label the most basic kind of existence that entities can have. It was usually opposed to *prajñaptisat*, 'existence as a designation' or 'secondary existence'. According to most varieties of Buddhist metaphysics, anything that can be an object of thought or designation must exist in some sense; but some things exist primarily really, in their own right (*dravyasat*), while others exist only as objects of linguistic reference (*prajñaptisat*). An example of the first kind would be a moment of physical form; an example of the second kind would be an ordinary object such as a pot, since this is composed of a series of existents of the first kind. P.J.G.

dream argument. See DESCARTES.

dreaming, a typically involuntary episode in which a sleeping subject experiences images and thoughts with some similarity to those experienced in waking life. 'Dreaming' can take either propositional or objectual complements, as in 'She is dreaming that she is flying' or 'She is dreaming of Jack'. Dreams are not in general veridical: in the former case, she might not be flying; in the latter, Jack might not exist. These points apply to a significant degree to daydreaming, except that the subject is not asleep during the episodes in question. Daydreaming also admits of more voluntary control than does dreaming.

The greatest philosophical interest in dreaming concerns its epistemic significance, particularly as a skeptical scenario: since dreaming involves experiences that resemble waking experience, philosophers – most famously, Descartes in the *Meditations* – have wondered what grounds we have for our ordinary perceptual beliefs. If someone takes herself to be looking out the window on a sunny day, how can she know it really is sunny? Mightn't she simply be asleep, dreaming that it is sunny? Considerations like this form an important part of Descartes's method of doubt, on which only propositions beyond rational doubt merit belief; and such considerations threaten to undermine nearly all ordinary knowledge. Although other skeptical scenarios, such as Descartes's "evil demon" scenario, play similar roles, dreaming is particularly interesting in that dreams, unlike evil demons, are commonplace.

One strategy against dream skepticism seeks to locate important differences between dream experience and waking experience. For example, J. L. Austin viewed "dream-like quality" as a distinguishing mark of dreams; and some contemporary philosophers hold that dreaming involves imaginative faculties distinct from those of waking perception. Some philosophers have even challenged the assumption that dreaming involves experience of any kind, suggesting that one wakes with a false memory as of having had sleeping experiences. This idea, defended in Malcolm's *Dreaming* (1962), has little contemporary traction, due in part to the improved psychological understanding of dreaming and REM sleep that emerged shortly after the publication of Malcolm's book. Dreaming also plays a significant role in Freudian psychoanalysis. Freud theorized that dreams in general represent a subconscious form of wish fulfillment.

Dretske, Fred (1932–2013), American philosopher best known for his externalistic representational naturalism about experience, belief, perception, and knowledge. Educated at Purdue University and the University of Minnesota, he taught at the University of Wisconsin (1960–88), Stanford University (1988–98), and Duke University (part-time for a number of years after leaving Stanford).

In *Seeing and Knowing* (1969) Dretske develops an account of *non-epistemic seeing*, denying that seeing is believing – that for a subject *S* to see a dog, say, *S* must apply a concept to it (dog, animal, furry). The dog must look some way to *S* (*S* must visually differentiate the dog, but need not conceptually categorize it). This contrasts with *epistemic seeing*, where for *S* to *see that* a dog is before him, *S would* have to believe that it is a dog.

In *Knowledge and the Flow of Information* (1981), a mind-independent objective sense of 'information' is applied to propositional knowledge and belief content. 'Information' replaced Dretske's earlier notion of a 'conclusive reason' (1971). Knowing that *p* requires having a true belief caused or causally sustained by an event that carries the information that *p*. Also, the semantic content of a belief is identified with the most specific digitally encoded piece of information to which it becomes selectively sensitive during a period of learning.

In *Explaining Behavior* (1988), Dretske's account of representation (and misrepresentation) takes on a teleological flavor. The semantic meaning of a structure is now identified with its indicator function. A structure recruited for a causal role of indicating *F*'s, and sustained in that causal role by this ability, comes to mean *F* – thereby providing a causal role for the content of cognitive states and avoiding epiphenomenalism about semantic content.

In *Naturalizing the Mind* (1995), Dretske's theory of meaning is applied to the problems of consciousness and qualia. He argues that the empirically significant features of conscious experience are exhausted by their functional (and hence representational) roles of indicating external sensible properties. He rejects the views that consciousness is composed of a higher-order hierarchy of mental states and that qualia are due to intrinsic, non-representational features of the underlying physical systems.

Dretske is also known for his contributions on the nature of contrastive statements, laws of nature, causation, and epistemic non-closure, among other topics.

dualism, the view that reality consists of two disparate parts. The crux of dualism is an apparently unbridgeable gap between two incommensurable orders of being that must be reconciled if our assumption that there is a comprehensible universe is to be justified. Dualism is exhibited in the pre-Socratic division between appearance and reality; Plato's realm of being containing eternal Ideas and realm of becoming containing changing things; the medieval division between finite man and infinite God; Descartes's substance dualism of thinking mind and extended matter; Hume's separation of fact from value; Kant's division between empirical phenomena and transcendental noumena; the epistemological double-aspect theory of James and Russell, who postulate a neutral substance that can be understood in separate ways as either mind or brain; and Heidegger's separation of being and time that inspired Sartre's contrast of being and nothingness. The doctrine of two truths, the sacred and the profane or the religious and the secular, is a dualistic response to the conflict between religion and science.

Descartes's dualism is taken to be the source of the mind-body problem. If the mind is active unextended thinking and the body is passive unthinking extension, how can these essentially unlike and independently existing substances interact causally, and how can mental ideas represent material things? How, in other words, can the mind know and influence the body, and how can the body affect the mind? Descartes said that mind and body interact and that ideas represent material things without resembling them, but he could not explain how, and concluded merely that God makes these things happen. Proposed dualist solutions to the mind-body problem are Malebranche's occasionalism (mind and body do not interact but God makes them appear to); Leibniz's preestablished harmony among non-interacting monads; and Spinoza's property dualism of mutually exclusive but parallel attributes expressing the one substance God. Recent mind-body dualists are Popper and John C. Eccles. Monistic alternatives to dualism include Hobbes's view that the mental is merely the epiphenomena of the material; Berkeley's view that material things are collections of mental ideas; and the contemporary materialist view of Smart, Armstrong, and Paul and Patricia Churchland that the mind is the brain. A classic treatment of these matters is Arthur O. Lovejoy's *The Revolt Against Dualism*.

Dualism is related to binary thinking – i.e., to systems of thought that are two-valued, such as logic in which theorems are valid or invalid, epistemology in which knowledge claims are true or false, and ethics in which individuals are good or bad and their actions are right or wrong. In *The Quest for Certainty*, Dewey finds that all modern problems of philosophy derive from dualistic oppositions, particularly between spirit and nature. Like Hegel, he proposes a synthesis of oppositions seen as theses versus antitheses. Recent attacks on the view that dualistic divisions can be explicitly described or maintained have been made by Wittgenstein, who offers instead a classification scheme based on overlapping family resemblances; by Quine, who casts doubt on the division between analytic or formal truths based on meanings and synthetic or empirical truths based on facts; and by Derrida, who challenges our ability to distinguish between the subjective and the objective. But despite the extremely difficult problems posed by ontological dualism, and despite the cogency of many arguments against dualistic thinking, Western philosophy continues to be predominantly dualistic, as witnessed by the indispensable use of two-valued matrixes in logic and ethics and by the intractable problem of rendering mental intentions in terms of material mechanisms or vice versa.

dualism, ethical. See ZOROASTRIANISM.

Ducasse, C(urt) J(ohn) (1881–1969), French-born American philosopher of mind and aesthetician. He arrived in the United States in 1900, received his Ph.D. from Harvard (1912), and taught at the University of Washington (1912–26) and Brown University (1926–58).

His most important work is *Nature, Mind and Death* (1951). The key to his general theory is a non-Humean view of causation: the relation of causing is triadic, involving (i) an initial event, (ii) the set of conditions under which it occurs, and (iii) a resulting event; the initial event is the cause, and the resulting event is the effect. On the basis of this view he constructed a theory of categories – an explication of such concepts as those of substance, property, mind, matter, and body. Among the theses he defended were that minds are substances, that they causally interact with bodies, and that human beings are free despite every event's having a cause. In *A Critical Examination of the Belief in a Life after Death* (1961), he concluded that "the balance of the evidence so far obtained is on the side of . . . survival." Like Schopenhauer, whom he admired, Ducasse was receptive to the religious and philosophical writings of the Far East. He wrote with remarkable objectivity on the philosophical problems associated with so-called paranormal phenomena.

Ducasse's epistemological views are developed in *Truth, Knowledge and Causation* (1968). He sets forth a realistic theory of perception (he says, about sense-qualities, "Berkeley is right and the realists are wrong" and, about material things, "The realists are right and Berkeley is wrong"). He provides the classical formulation of the "adverbial theory" of sense-qualities, according to which such qualities are not *objects* of experience or awareness but *ways* of experiencing or of being aware. One does not perceive a red material object by sensing a red sense-datum; for then perceiving would involve *three* entities – (i) the perceiving subject, (ii) the red sense-datum, and (iii) the red material object. But one may perceive a red material object by sensing redly; then the only entities involved are (i) the perceiving subject and (ii) the material object. Ducasse observes that, analogously, although it may be natural to say "dancing a waltz," it would be more accurate to speak of "dancing waltzily."

See also PERCEPTION, PHILOSOPHY OF MIND.
R.M.C.

duck-rabbit, an ambiguous figure (not an illusion, as is sometimes said) most strongly associated with Wittgenstein (*Philosophical Investigations*, Part II, Section xi), though Wittgenstein attributes it to Joseph Jastrow (*Fact and Fable in Psychology*, 1900), who got it from *Harper's Weekly* (November 19, 1892), which based its drawing on one published in *Fliegende Blätter*, a German humor magazine (October 23, 1892). Wittgenstein uses the figure to illustrate the distinction between seeing (the figure) and seeing an aspect (seeing the figure *as* a duck or rabbit). He notes that someone might look at the figure and see just a picture-duck, unaware that the figure can be seen otherwise and unaware that he is seeing the figure *as* a duck. Someone who has caught on to the alternative ways of seeing the figure can switch back and forth at will between the two impressions, demonstrating that perception is not wholly a matter of *sensory* impressions, but also depends on the way the subject organizes or construes what is presented to the senses. Wittgenstein points out that settings, backgrounds, and captions can strongly predispose the viewer to see the figure one way or the other. **See also** FIGURE-GROUND.
R.C.Ro.

Duhem, Pierre-Maurice-Marie (1861–1916), French physicist who wrote extensively on the history and philosophy of science. Like Georg Helm, Wilhelm Ostwald, and others, he was an energeticist, believing generalized thermodynamics to be the foundation of all of physics and chemistry. Duhem spent his whole scientific life advancing energetics, from his failed dissertation in physics (a version of which was accepted as a dissertation in mathematics), published as *Le potentiel thermodynamique* (1886), to his mature treatise, *Traité d'énergétique* (1911). His scientific legacy includes the Gibbs-Duhem and Duhem-Margules equations. Possibly because his work was considered threatening by the Parisian scientific establishment or because of his right-wing politics and fervent Catholicism, he never obtained the position he merited in the intellectual world of Paris. He taught at the provincial universities of Lille, Rennes, and, finally, Bordeaux.

Duhem's work in the history and philosophy of science can be viewed as a defense of the aims and methods of energetics; whatever Duhem's initial motivation, his historical and philosophical work took on a life of its own. Topics of interest to him included the relation between history of science and philosophy of science, the nature of conceptual change, the historical structure of scientific knowledge, and the relation between science and religion. Duhem was an anti-atomist (or anti-Cartesian); in the contemporary debates about light and magnetism, Duhem's anti-atomist stance was also directed against the work of Maxwell. According to Duhem, atomists resolve the bodies perceived by the senses into smaller, imperceptible bodies. The explanation of observable phenomena is then referred to these imperceptible bodies and their motions, suitably combined. Duhem's rejection of atomism was based on his instrumentalism (or fictionalism): physical theories are not explanations but representations; they do not reveal the true nature of matter, but give general rules of which laws are particular cases; theoretical propositions are not true or false, but convenient or inconvenient. An important reason for treating physics as non-explanatory was Duhem's claim that there is general consensus in physics and none in metaphysics – thus his insistence on the autonomy of physics from metaphysics. But he also thought that scientific representations become more complete over time until they gain the status of a natural classification. Accordingly, Duhem attacked the use of models by some scientists, e.g. Faraday and Maxwell. Duhem's rejection of atomism was coupled with a rejection of *inductivism*, the doctrine that the only physical principles are general laws known through induction, based on observation of facts. Duhem's rejection forms a series of theses collectively known as the *Duhem thesis:* experiments in physics are observations of phenomena accompanied by interpretations; physicists therefore do not submit single hypotheses, but whole groups of them, to the control of experiment; thus, experimental evidence alone cannot conclusively falsify hypotheses. For similar reasons, Duhem rejected the possibility of a crucial experiment. In his historical studies, Duhem argued that there were no abrupt discontinuities between medieval and early modern science – the so-called *continuity thesis;* that religion played a positive role in the development of science in the Latin West; and that the history of physics could be seen as a cumulative whole, defining the direction in which progress could be expected.

Duhem's philosophical works were discussed by the founders of twentieth-century philosophy of science, including Mach, Poincaré, the members of the Vienna Circle, and Popper. A revival of interest in Duhem's philosophy began with

Quine's reference in 1953 to the Duhem thesis (also known as the *Duhem-Quine thesis*). As a result, Duhem's philosophical works were translated into English – as *The Aim and Structure of Physical Theory* (1954) and *To Save the Phenomena* (1969). By contrast, few of Duhem's extensive historical works – *Les origines de la statique* (2 vols., 1906–1908), *Études sur Léonard de Vinci* (3 vols., 1906–13), and *Système du monde* (10 vols., 1913–59), e.g. – have been translated, with five volumes of the *Système du monde* actually remaining in manuscript form until 1954–59. Unlike his philosophical work, Duhem's historical work was not sympathetically received by his influential contemporaries, notably George Sarton. His supposed main conclusions were rejected by the next generation of historians of science, who presented modern science as discontinuous with that of the Middle Ages. This view was echoed by historically oriented philosophers of science who, from the early 1960s, emphasized discontinuities as a recurrent feature of change in science, e.g. Kuhn in *The Structure of Scientific Revolutions* (1962).

Duhem thesis. See DUHEM.

Dummett, Michael A. E. (1925–2011), British philosopher of language, logic, and mathematics, noted for his sympathy for metaphysical antirealism and for his exposition of the philosophy of Frege. Dummett regards allegiance to the principle of bivalence as the hallmark of a realist attitude toward any field of discourse. This is the principle that any meaningful assertoric sentence must be determinately either true or else false, independently of anyone's ability to ascertain its truth-value by recourse to appropriate empirical evidence or methods of proof. According to Dummett, the sentences of any learnable language cannot have verification-transcendent truth conditions and consequently we should query the intelligibility of certain statements that realists regard as meaningful. On these grounds, he calls into question realism about the past and realism in the philosophy of mathematics in several of the papers in two collections of his essays, *Truth and Other Enigmas* (1978) and *The Seas of Language* (1993).

In *The Logical Basis of Metaphysics* (1991), Dummett makes clear his view that the fundamental questions of metaphysics have to be approached through the philosophy of language, and more specifically through the theory of meaning. Here his philosophical debts to Frege and Wittgenstein are manifest. Dummett has been the world's foremost expositor and champion of Frege's philosophy, above all in two highly influential books, *Frege: Philosophy of Language* (1973) and *Frege: Philosophy of Mathematics* (1991). This is despite the fact that Frege himself advocated a form of Platonism in semantics and the philosophy of mathematics that is quite at odds with Dummett's own antirealist inclinations. It would appear, however, from what Dummett says in *Origins of Analytical Philosophy* (1993), that he regards Frege's great achievement as that of having presaged the "linguistic turn" in philosophy that was to see its most valuable fruit in the later work of Wittgenstein. Wittgenstein's principle that grasp of the meaning of a linguistic expression must be exhaustively manifested by the use of that expression is one that underlies Dummett's own approach to meaning and his anti-realist leanings. In logic and the philosophy of mathematics this is shown in Dummett's sympathy for the intuitionistic approach of Brouwer and Heyting, which involves a repudiation of the law of excluded middle, as set forth in Dummett's own book on the subject, *Elements of Intuitionism* (1977).

E.J.L.

dunamis, also *dynamis* (Greek, 'power', 'capacity'), as used by pre-Socratics such as Anaximander and Anaxagoras, one of the elementary character-powers, such as the hot or the cold, from which they believed the world was constructed. Plato's early theory of Forms borrowed from the concept of character-powers as causes present in things; courage, e.g., is treated in the *Laches* as a power in the soul. Aristotle also used the word in this sense to explain the origins of the elements. In the *Metaphysics* (especially Book IX), Aristotle used *dunamis* in a different sense to mean 'potentiality' in contrast to 'actuality' (*energeia* or *entelecheia*). In the earlier sense of *dunamis*, matter is treated as potentiality, in that it has the potential to receive form and so be actualized as a concrete substance. In the later Aristotelian sense of *dunamis*, dormant abilities are treated as potentialities, and *dunamis* is to *energeia* as sleeping is to waking, or having sight to seeing. **See also** ARISTOTLE, ENERGEIA. P.Wo.

Duns Scotus, John (1266–1308), Scottish Franciscan metaphysician and philosophical theologian. He lectured at Oxford, Paris, and Cologne, where he died and his remains are still venerated. Modifying Avicenna's conception of metaphysics as the science of being *qua* being, but univocally conceived, Duns Scotus showed its goal was to demonstrate God as the Infinite Being (revealed to Moses as the "I am who am"), whose creative will is the source of the world's contingency. Out of love God fashioned each creature with a unique "haecceity" or particularity formally distinct from its individualized nature. Descriptively identical with others of its kind, this nature, conceived in abstraction from haecceity, is both objectively real and potentially universal, and provides the basis for scientific knowledge that Peirce calls "Scotistic realism."

Duns Scotus brought many of Augustine's insights, treasured by his Franciscan predecessors, into the mainstream of the Aristotelianism of his day. Their notion of the will's "supersufficient potentiality" for self-determination he showed can be reconciled with Aristotle's notion of an "active potency," if one rejects the controversial principle that "whatever is moved is moved by another." Paradoxically, Aristotle's criteria for rational and non-rational potencies prove the rationality of the will, not the intellect, for he claimed that only rational faculties are able to act in opposite ways and are thus the source of creativity in the arts. If so, then intellect, with but one mode of acting determined by objective evidence, is non-rational, and so is classed with active potencies called collectively "nature." Only the will, acting "with reason," is free to will or nill this or that. Thus "nature" and "will" represent Duns Scotus's primary division of active potencies, corresponding roughly to Aristotle's dichotomy of non-rational and rational. Original too is his development of Anselm's distinction of the will's twofold inclination or "affection": one for the advantageous, the other for justice. The first endows the will with an "intellectual appetite" for happiness and actualization of self or species; the second supplies the will's specific difference from other natural appetites, giving it an innate desire to love goods objectively according to their intrinsic worth. Guided by right reason, this "affection for justice" inclines the will to act ethically, giving it a congenital freedom from the need always to seek the advantageous. Both natural affections can be supernaturalized, the "affection for justice" by charity, inclining us to love God above all and for his own sake; the affection for the advantageous by the virtue of hope, inclining us to love God as our ultimate good and future source of beatitude.

Another influential psychological theory is that of intuitive intellectual cognition, or the simple, non-judgmental awareness of a here-and-now existential situation. First developed as a necessary theological condition for the face-to-face vision of God in the next life, intellectual intuition is needed to explain our certainty of primary contingent truths, such as 'I think', 'I choose', and our awareness of existence. Unlike Ockham, Duns Scotus never made intellectual intuition the basis for his epistemology, nor believed it puts one in direct contact with any extramental substance material or spiritual, for in this life, at least, our intellect works through the sensory imagination. Intellectual intuition seems to be that indistinct peripheral aura associated with each direct sensory-intellectual cognition. We know of it explicitly only in retrospect when we consider the necessary conditions for intellectual memory. It continued to be a topic of discussion and dispute down to the time of Calvin, who, influenced by the Scotist John Major, used an auditory rather than a visual sense model of intellectual intuition to explain our "experience of God."

A.B.W.

Dutch book, a bet or combination of bets whereby the bettor is bound to suffer a net loss regardless of the outcome. A simple example would be a bet on a proposition *p* at odds of 3:2 combined with a bet on not-*p* at the same odds, the total amount of money at stake in each bet being five dollars. Under this arrangement, if *p* turned out to be true one would win two dollars by the first bet but lose three dollars by the second, and if *p* turned out to be false one would win two dollars by the second bet but lose three dollars by the first. Hence, whatever happened, one would lose a dollar. **See also** PROBABILITY. R.Ke.

Dutch book argument, the argument that a rational person's degrees of belief must conform to the axioms of the probability calculus, since otherwise, by the Dutch book theorem, he would be vulnerable to a Dutch book. **See also** DEGREES OF BELIEF. R.Ke.

Dutch book theorem, the proposition that anyone who (a) counts a bet on a proposition *p* as fair if the odds correspond to his degree of belief that *p* is true and who (b) is willing to make any combination of bets he would regard individually as fair will be vulnerable to a Dutch book, provided his degrees of belief do not conform to the axioms of the probability calculus. Thus, anyone of whom (a) and (b) are true and whose degree of belief in a disjunction of two incompatible propositions is not equal to the sum of his degrees of belief in the two propositions taken individually would be vulnerable to a Dutch book. R.Ke.

duty, what a person is obligated or required to do. Duties can be moral, legal, parental, occupational, etc., depending on their foundations or grounds. Because a duty can have several different grounds, it can be, say, both moral and legal, though it need not be of more than one type. *Natural duties* are moral duties people have simply in virtue of being persons, i.e. simply in virtue of their nature. There is a *prima facie duty* to do something if and only if there is an appropriate basis for doing that thing. For instance, a prima facie moral duty will be one for which there is a moral basis, i.e. some moral grounds. This contrasts with an all-things-considered duty, which is a duty one has if the appropriate grounds that support it outweigh any that count against it.

Negative duties are duties not to do certain things, such as to kill or harm, while *positive duties* are duties to act in certain ways, such as to relieve suffering or bring aid. While the question of precisely how to draw the distinction between negative and positive duties is disputed, it is generally thought that the violation of a negative duty involves an agent's causing some state of affairs that is the basis of the action's wrongness (e.g., harm, death, or the breaking of a trust), whereas the violation of a positive duty involves an agent's allowing those states of affairs to occur or be brought about.

Imperfect duties are, in Kant's words, "duties which allow leeway in the interest of inclination," i.e. that permit one to choose among several possible ways of fulfilling them. *Perfect duties* do not allow that leeway. Thus, the duty to help those in need is an imperfect duty since it can be fulfilled by helping the sick, the starving, the oppressed, etc., and if one chooses to help, say, the sick, one can choose which of the sick to help. However, the duty to keep one's promises and the duty not to harm others are perfect duties since they do not allow one to choose which promises to keep or which people not to harm. Most positive duties are imperfect; most negative ones, perfect.

duty-making. See GOOD-MAKING CHARACTERISTIC.

du Vair, Guillaume (1556–1621), French philosopher, bishop, and political figure. Du Vair and Justus Lipsius were the two most influential propagators of neo-Stoicism in early modern Europe. Du Vair's *Sainte Philosophie* ("Holy Philosophy," 1584) and his shorter *Philosophie morale des Stoïques* ("Moral Philosophy of the Stoics," 1585) were translated and frequently reprinted. The latter presents Epictetus in a form usable by ordinary people in troubled times. We are to follow nature and live according to reason; we are not to be upset by what we cannot control; virtue is the good. Du Vair inserts, moreover, a distinctly religious note. We must be pious, accept our lot as God's will, and consider morality obedience to his command. Du Vair thus Christianized Stoicism, making it widely acceptable. By teaching that reason alone enables us to know how we ought to live, he became a founder of modern rationalism in ethics. **See also** ETHICS, HUMAN NATURE, STOICISM. J.B.S.

Dvaita Vedanta, a variety of Hinduism according to which Brahman is an independently existing, omnipotent, omniscient personal deity. In Dvaita Vedanta, Brahman everlastingly sustains in existence a world of minds and physical things without their being properly viewed as the body of Brahman, since this would mistakenly suggest that Brahman is limited and can be affected in ways analogous to those in which human beings are limited and can be affected by their bodies. The Upanishadic texts concerning the individual *Ātman*'s identity to Brahman, and all things being in Brahman, are understood as asserting dependence on Brahman and resemblance to Brahman rather than numerical identity with Brahman. Each person is held to have his or her own essence (cf. the medieval Scholastic notion of a *haecceity*) and accordingly some are destined for enlightenment, some for endless transmigration, and some for misery. K.E.Y.

Dworkin, Ronald M. (1931–2013), American jurist, political philosopher, and central contributor to recent legal and political theory. He served as professor of jurisprudence, University of Oxford (1969–98), professor of law, New York University (1975–2013), and (for many years beginning in 1998) also Professor of Jurisprudence at University College, London. He was the first significant critic of Hart's positivist analysis of law as based on a determinable set of social rules. Dworkin argues that the law contains legal principles as well as legal rules. Legal principles are standards phrased generally (e.g., 'No one shall profit from his own wrong'); they do not have a formal "pedigree," but are requirements of morality. Nonetheless, courts are obliged to apply such principles, and thus have no lawmaking discretion. Judicially enforceable legal rights must derive from antecedent political rights. Dworkin characterizes rights as political "trumps" – hence his title *Taking Rights Seriously* (2d ed., 1978), which collects the papers that defend the views sketched.

Dworkin postulates an idealized judge, Hercules, who can invariably determine what rights are legally enforceable. Dworkin denies any metaphysical commitments thereby, and emphasizes instead the constructive and interpretive nature of both adjudication and legal theory. These arguments are made in papers collected in *A Matter of Principle* (1985). *Law's Empire* (1986) systematizes his view. He presents there a theory of "law as integrity." The court's obligation is to make the community's law the best it can be by finding decisions that best fit both institutional history and moral principle. Hercules always best determines the best fit.

Dworkin also contributed to substantive political theory. He defends a form of liberalism that makes equality as prominent as liberty. His account of equality is found in a number of independent papers; see, e.g., "Foundations of Liberal Equality," *Tanner Lectures on Human Values XI* (1990). Dworkin applied his liberal theory in two ways. He continually acted as a critical watchdog of the U.S. Supreme Court, assessing decisions for their adherence to the ideals of principle, respect for equality, and achievement of best fit. Some of these essays are in the two collections mentioned; more recent papers are in *Freedom's Law* (1996). *Life's Dominion* (1993) derives from these ideals an account of abortion and euthanasia. Among Dworkin's more recent books are *Sovereign Virtue: The Theory and Practice of Equality* (2000); *Justice in Robes* (2007); and *Justice for Hedgehogs* (2011).

Dworkin's philosophizing has a conceptual richness and rhetorical fire that, when not wholly under control, give his theoretical positions a protean quality at the level of detail. Nonetheless, the ideas that adjudication should be principled and enforce rights, and that we all deserve equal dignity and respect, exercise a powerful fascination.

dynamic logic, a branch of logic in which, in addition to the usual category of formulas interpretable as propositions, there is a category of expressions interpretable as actions. Dynamic logic (originally called the modal logic of programs) emerged in the late 1970s as one step in a long tradition within theoretical computer science aimed at providing a way to formalize the analysis of programs and their action. A particular concern here was program verification: what can be said of the effect of a program if started at a certain point? To this end operators $[\alpha]$ and $<\alpha>$ were introduced with the following intuitive readings: $[\alpha]A$ to mean '*after every* terminating computation according to α it is the case that A' and $<\alpha>A$ to mean '*after some* terminating computation according to α it is the case that A'. The logic of these operators may be seen as a generalization of ordinary modal logic: where modal logic has one box operator $\Box$ and one diamond operator $\Diamond$, dynamic logic has one box operator $[\alpha]$ and one diamond operator $<\alpha>$ for every program expression α in the language.

In possible worlds semantics for modal logic, a model is a triple (U, R, V) where U is a universe of points, R a binary relation, and V a valuation assigning to each atomic formula a subset of U. In dynamic logic, a model is a triple (U, R, V) where U and V are as before but R is a family of binary relations $R(\alpha)$, one for every program expression α in the language. Writing '$|=x\ A$', where x is a point in U, for 'A is true at x' (in the model in question), we have the following characteristic truth conditions (truth-functional compounds are evaluated by truth tables, as in modal logic):

> $|=x\ P$ if and only if x is a point in $V(P)$, where P is an atomic formula,
>
> $|=x\ [\alpha]A$ if and only if, for *all* y, if x is $R(\alpha)$-related to y then $|=y\ A$,
>
> $|=x\ <\alpha>$ if and only if, for *some* y, x is $R(\alpha)$-related to y and $|=y\ A$.

Traditionally, dynamic logic will contain machinery for rendering the three regular operators on programs: '+' (sum), ';' (composition), and '*' (Kleene's star operation), as well as the test operator '?', which, operating on a proposition, will yield a program. The action $\alpha + \beta$ consists in carrying out α or carrying out β; the action $\alpha; \beta$ in first carrying out α, then carrying out β; the action α^* in carrying out α some finite number of times (not excluding 0); the action *?*

A in verifying that A. Only standard models reflect these intuitions:

$$R(\alpha + \beta) = R(\alpha) \cup R(\beta),$$

$$R(\alpha; \beta) = R(\alpha) \mid R(\beta),$$

$$R(\alpha^*) = (R(\alpha))^*,$$

$$R(?A) = \{(x, x) : \models x\ A\}$$

(where '*' is the ancestral star)

The smallest propositional dynamic logic (PDL) is the set of formulas true at every point in every standard model. Note that dynamic logic analyzes non-deterministic action – this is evident at the level of atomic programs π where $R(\pi)$ is a relation, not necessarily a function, and also in the definitions of $R(\alpha + \beta)$ and $R(\alpha^*)$.

Dynamic logic has been extended in various ways, e.g. to first- and second-order predicate logic. Furthermore, just as deontic logic, tense logic, etc., are referred to as modal logic in the wide sense, so extensions of dynamic logic in the narrow sense such as process logic are often loosely referred to as dynamic logic in the wide sense.

The philosophical interest in dynamic logic rests with the expectation that it will prove a fruitful instrument for analyzing the concept of action in general: a successful analysis would be valuable in itself and would also be relevant to other disciplines such as deontic logic and the logic of imperatives.

E

Eckhart, Johannes, called Meister Eckhart (c.1260–1328), German mystic, theologian, and preacher. Eckhart entered the Dominican order early and began an academic circuit that took him several times to Paris as a student and master of theology and that initiated him into ways of thinking much influenced by Albertus Magnus and Thomas Aquinas. At Paris, Eckhart wrote the required commentary on the *Sentences* of Peter Lombard and finished for publication at least three formal disputations. But he had already held office within the Dominicans, and he continued to alternate work as administrator and as teacher. Eckhart preached throughout these years, and he continued to write spiritual treatises in the vernacular, of which the most important is the *Book of Divine Consolation* (1313/22). Only about a third of Eckhart's main project in Latin, the *Opus tripartitum*, seems to have been completed.

Beginning in the early 1320s, questions were raised about Eckhart's orthodoxy. The questions centered on what was characteristic of his teaching, namely the emphasis on the soul's attaining "emptiness" so as to "give birth to God." The soul is ennobled by its emptying, and it can begin to "labor" with God to deliver a spark that enacts the miraculous union-and-difference of their love. After being acquitted of heresy once, Eckhart was condemned on 108 propositions drawn from his writings by a commission at Cologne. The condemnation was appealed to the Holy See, but in 1329 Eckhart was there judged "probably heretical" on 17 of 28 propositions drawn from both his academic and popular works. The condemnation clearly limited Eckhart's explicit influence in theology, though he was deeply appropriated not only by mystics such as Johannes Tauler and Henry Suso, but by church figures such as Nicholas of Cusa and Martin Luther. He has since been taken up by thinkers as different as Hegel, Fichte, and Heidegger.

Eco, Umberto (b.1932), Italian philosopher, intellectual historian, and novelist. A leading figure in semiotics, the theory of signs, Eco has devoted most of his vast production to the notion of interpretation and its role in communication. In the 1960s, building on the idea that active interpretation is required to take any sign as a sign, he pioneered reader-oriented criticism (*The Open Work*, 1962, 1976; *The Role of the Reader*, 1979) and championed a holistic view of meaning, holding that all of the interpreter's beliefs, i.e. his encyclopedia, potentially bear on word meaning. In the 1970s, equally influenced by Peirce and the French structuralists, he offered a unified theory of signs (*A Theory of Semiotics*, 1976), aimed at grounding the study of communication. He opposed the idea of communication as a natural process, steering a middle way between realism and idealism, particularly of the Sapir-Whorf variety. The issue of realism also looms large in his recent work. In *The Limits of Interpretation* (1990) and *Interpretation and Overinterpretation* (1992), he attacks deconstructionism. *Kant and the Platypus* (1997) defends a "contractarian" form of realism, holding that the reader's interpretation is needed to fix reference.

In his historical essays, ranging from medieval aesthetics (*The Aesthetics of Thomas Aquinas*, 1956) to the attempts at constructing artificial and "perfect" languages (*The Search for the Perfect Language*, 1993) to medieval semiotics, he traces the origins of some central notions in contemporary philosophy of language (e.g., meaning, symbol, denotation), and such recent concerns as the language of mind and translation, to larger issues in the history of philosophy. His novels are pervaded by philosophical queries, such as whether the world is an ordered whole (*The Name of the Rose*, 1980) and how much interpretation one can tolerate without falling prey to some conspiracy syndrome (*Foucault's Pendulum*, 1988). Everywhere, he engages the reader in the game of (controlled) interpretations.

eduction, the process of initial clarification, as of a phenomenon, text, or argument, that normally takes place prior to logical analysis. Out of the flux of vague and confused experiences certain characteristics are drawn into some kind of order or intelligibility in order that attention can be focused on them (Aristotle, *Physics* I). These characteristics often are latent, hidden, or implicit. The notion often is used with reference to texts as well as experience. Thus it becomes closely related to exegesis and hermeneutics, tending to be reserved for the sorts of clarification that precede formal or logical analyses. **See also** **HERMENEUTICS.** F.S.

Edwards, Jonathan (1703–58), American philosopher and theologian who was educated at Yale, preached in New York City, and in 1729 assumed a Congregational pastorate in Northampton, Massachusetts, where he became a leader in the Great Awakening. Because of a dispute with his parishioners over qualifications for communion, he was forced to leave in 1750. In 1751, he took charge of congregations in Stockbridge, a frontier town sixty miles to the west. He was elected third president of Princeton in 1757 (but died shortly after inauguration).

Edwards deeply influenced Congregational and Presbyterian theology in America for over a century, but had little impact on philosophy. Interest in him revived in the middle of the twentieth century, first among literary scholars and theologians and later among philosophers. While most of Edwards's published work defends the Puritan version of Calvinist orthodoxy, his notebooks reveal an interest in philosophical problems for their own sake. Although he was indebted to Continental rationalists like Malebranche, to the Cambridge Platonists, and especially to Locke, his own contributions are sophisticated and original.

The doctrine of God's absolute sovereignty is explicated by occasionalism, a subjective idealism similar to Berkeley's, and phenomenalism. According to Edwards, what are "vulgarly" called causal relations are mere constant conjunctions. *True* causes necessitate their effects. Since God's will alone meets this condition, God is the only true cause. He is also the only true substance. Physical objects are collections of ideas of color, shape, and other "corporeal" qualities. Finite minds are series of "thoughts" or "perceptions." Any substance underlying perceptions, thoughts, and "corporeal ideas" must be something that "subsists by itself, stands underneath, and keeps up" physical and mental qualities. As the only thing that does so, God is the only real substance. As the only true cause and the only real substance, God is "in effect being in general." God creates to communicate his glory. Since God's internal glory is constituted by his infinite knowledge of, love of, and delight in himself as the highest good, his "communication *ad extra*" consists in the knowledge of, love of, and joy in himself which he bestows upon creatures. The essence of God's internal and external glory is "holiness" or "true benevolence," a disinterested love of being in general (i.e., of God and the beings dependent on him). Holiness constitutes "true beauty," a divine splendor or radiance of which "secondary" (ordinary) beauty is an imperfect image. God is thus supremely beautiful and the world is suffused with his loveliness.

Vindications of Calvinist conceptions of sin and grace are found in *Freedom of the Will* (1754) and *Original Sin* (1758). The former includes sophisticated defenses of theological determinism and compatibilism. The latter contains arguments for occasionalism and interesting discussions of identity. Edwards thinks that natural laws determine kinds or species, and kinds or species determine criteria of identity. Since the laws of nature depend on God's "arbitrary" decision, God establishes criteria of identity. He can thus, e.g., constitute Adam and his posterity as "one thing."

Edwards's religious epistemology is developed in *A Treatise Concerning Religious Affections* (1746) and *On the Nature of True Virtue* (1765). The conversion experience involves the acquisition of a "new sense of the heart." Its core is the mind's apprehension of a "new simple idea," the idea of "true beauty." This idea is needed to properly understand theological truths. *True Virtue* also provides the fullest account of Edwards's ethics – a moral sense theory that identifies virtue with benevolence. Although indebted to contemporaries like Hutcheson, Edwards criticizes their attempts to construct ethics on secular foundations. True benevolence embraces being in general. Since God is, in effect, being in general, its essence is the love of God. A love restricted to family, nation, humanity, or other "private systems" is a form of self-love.

effective procedure, a step-by-step recipe for computing the values of a function. It determines what is to be done at each step, without requiring any ingenuity of anyone (or any machine) executing it. The input and output of the procedure consist of items that can be processed mechanically. Idealizing a little, inputs and outputs are often taken to be strings on a finite alphabet. It is customary to extend the notion to procedures for manipulating natural numbers, via a canonical notation. Each number is associated with a string, its numeral. Typical examples of effective procedures are the standard grade school procedures for addition, multiplication, etc. One can execute the procedures without knowing anything about the natural numbers. The term 'mechanical procedure' or 'algorithm' is sometimes also used. A function f is computable if there is an effective procedure A that computes f. For every m in the domain of f, if A were given m as input, it would produce $f(m)$ as output. Turing machines are mathematical models of effective procedures. Church's thesis, or Turing's thesis, is that a function is computable provided there is a Turing machine that computes it. In other words, for every effective procedure, there is a Turing machine that computes the same function. **See also** CHURCH'S THESIS, COMPUTER THEORY, TURING MACHINE. S.Sha.

egocentric particular, a word whose denotation is determined by identity of the speaker and/or the time, place, and audience of its utterance. Examples are generally thought to include 'I,' 'you', 'here', 'there', 'this', 'that', 'now', 'past', 'present', and 'future'. The term 'egocentric particular' was introduced by Russell in *An Inquiry into Meaning and Truth* (1940). Earlier, in "The Philosophy of Logical Atomism" (*Monist*, 1918–19), he called such words "emphatic particulars."

Some important questions arise regarding egocentric particulars. Are some egocentric particulars more basic than others so that the rest can be correctly defined in terms of them but they cannot be correctly defined in terms of the rest? Russell thought all egocentric particulars can be defined by 'this'; 'I', e.g., has the same meaning as 'the biography to which this belongs', where 'this' denotes a sense-datum experienced by the speaker. Yet, at the same time, 'this' can be defined by the combination 'what I now notice'. Must we use at least some egocentric particulars to give a complete description of the world? Our ability to describe the world from a speaker-neutral perspective, so that the denotations of the terms in our description are independent of when, where, and by whom they are used, depends on our ability to describe the world without using egocentric particulars. Russell held that egocentric particulars are not needed in any part of the description of the world.

See also CAUSAL THEORY OF PROPER NAMES, INDEXICAL, TOKEN-REFLEXIVE. P.Mar.

egocentric predicament, each person's apparently problematic position as an experiencing subject, assuming that all our experiences are private in that no one else can have them. Two problems concern our ability to gain empirical knowledge. First, it is hard to see how we gain empirical knowledge of what others experience, if all experience is private. We cannot have their experience to see what it is like, for any experience we have is our experience and so not theirs. Second, it is hard to see how we gain empirical knowledge of how the external world is, independently of our experience. All our empirically justified beliefs seem to rest ultimately on what is given in experience, and if the empirically given is private, it seems it can only support justified beliefs about the world as we experience it. A third major problem concerns our ability to communicate with others. It is hard to see how we describe the world in a language others understand. We give meaning to some of our words by defining them by other words that already have meaning, and this process of definition appears to end with words we define ostensively; i.e., we use them to name something given in experience. If experiences are private, no one else can grasp the meaning of our ostensively defined words or any words we use them to define. No one else can understand our attempts to describe the world. **See also** PRIVATE LANGUAGE ARGUMENT, PROBLEM OF OTHER MINDS. P.Mar.

egoism, any view that, in a certain way, makes the self central. There are several different versions of egoism, all concerning how actions relate to the self. *Ethical egoism* is the view that people ought to do what is in their own interest. *Psychological egoism* is a view about people's motives, inclinations, or dispositions. One statement of psychological egoism says that, as a matter of fact, people always do what they believe is in their self-interest and, human nature being what it is, they cannot do otherwise. Another says that people never desire anything for its own sake except what they believe is in their self-interest.

Altruism is the opposite of egoism. Any ethical view that implies that people sometimes ought to do what is in the interest of others and not in their self-interest can be considered a form of ethical altruism. The view that, human nature being what it is, people can do what they do not believe to be in their self-interest might be called *psychological altruism*. Different species of ethical and psychological egoism result from different interpretations of self-interest and of acting from self-interest, respectively. Some people have a broad conception of acting from self-interest such that people acting from a desire to help others can be said to be acting out of self-interest, provided they think doing so will not, on balance, take away from their own good. Others have a narrower conception of acting from self-interest such that one acts from self-interest only if one acts from the desire to further one's own happiness or good. Butler identified self-love with the desire to further one's own happiness or good and self-interested action with action performed from that desire alone. Since we obviously have other particular desires, such as the desire for honor, for power, for revenge, and to promote the good of others, he concluded that psychological egoism was false. People with a broader conception of acting from self-interest would ask whether anyone with those particular desires would act on them if they believed that, on balance, acting on them would result in a loss of happiness or good for themselves. If some would, then psychological egoism is false, but if, given human nature as it is, no one would, it is true even if self-love is not the only source of motivation in human beings.

Just as there are broader and narrower conceptions of acting from self-interest, there are broader and narrower conceptions of self-interest itself, as well as subjective and objective conceptions of self-interest. Subjective conceptions relate a person's self-interest solely to the satisfaction of his desires or to what that person believes will make his life go best for him. Objective conceptions see self-interest, at least in part, as independent of the person's desires and beliefs. Some conceptions of self-interest are narrower than others, allowing that the satisfaction of only certain desires is in a person's self-interest, e.g. desires whose satisfaction makes that person's life go better for her. And some conceptions of self-interest count only the satisfaction of idealized desires, ones that someone would have after reflection about the nature of those desires and what they typically lead to, as furthering a person's self-interest.

Einfühlung (German, 'feeling into'), empathy. In contrast to sympathy, where one's identity is preserved in feeling with or for the other, in empathy, or *Einfühlung*, one tends to lose oneself in the other. The concept of *Einfühlung* received its classical formulation in the work of Theodor Lipps, who characterized it as a process of involuntary, inner imitation whereby a subject identifies through feeling with the movement of another body, whether it be the real leap of a dancer or the illusory upward lift of an architectural column. Complete empathy is considered to be aesthetic, providing a non-representational access to beauty. Husserl used a phenomenologically purified concept of *Einfühlung* to account for the way the self directly recognizes the other. Husserl's student Edith Stein described *Einfühlung* as a blind mode of knowledge that reaches the experience of the other without possessing it.

Einfühlung is not to be equated with *Verstehen*, or human understanding, which, as Dilthey pointed out, requires the use of all one's mental powers, and cannot be reduced to a mere mode of feeling. To understand is not to apprehend something empathetically as the projected locus of an actual experience, but to apperceive the meaning of expressions of experience in relation to their context. Whereas understanding is reflective, empathy is prereflective.

R.A.M.

Einstein, Albert (1879–1955), German-born American physicist, founder of the special and general theories of relativity, and a fundamental contributor to several branches of physics and to the philosophical analysis and critique of modern physics, notably of relativity and the quantum theory. Einstein was awarded the Nobel Prize in Physics in 1922, "especially for his discovery of the law of the photoelectric effect."

Born in Ulm in the German state of Württemberg, Einstein studied physics at the Polytechnic in Zürich. He was called to Berlin as director of the Kaiser Wilhelm Institute for Physics (1914) at the peak of the German ultranationalism that surrounded World War I. His reaction was to circulate an internationalist "Manifesto to Europeans" and to pursue Zionist and pacifist programs. Following the dramatic confirmation of the general theory of relativity (1919) Einstein became an international celebrity. This fame also made him the frequent target of German anti-Semites, who, during one notable episode, described the theory of relativity as "a Jewish fraud." In 1933 Einstein left Germany for the Institute for Advanced Study in Princeton. Although his life was always centered on science, he was also engaged in the politics and culture of his times. He carried on an extensive correspondence (whose publication will run to over forty volumes) with both famous and ordinary people, including significant philosophical correspondence with Cassirer, Reichenbach, Moritz Schlick, and others. Despite reservations over logical positivism, he was something of a patron of the movement, helping to secure academic positions for several of its leading figures. In 1939 Einstein signed a letter drafted by the nuclear physicist Leo Szilard informing President Roosevelt about the prospects for harnessing atomic energy and warning of the German efforts to make a bomb. Einstein did not further participate in the development of atomic weapons, and later was influential in the movement against them. In 1952 he was offered, and declined, the presidency of Israel. He died still working on a unified field theory, and just as the founders of the Pugwash movement for nuclear disarmament adopted a manifesto he had cosigned with Russell.

Einstein's philosophical thinking was influenced by early exposure to Kant and later study of Hume and Mach, whose impact shows in the operationalism used to treat time in his famous 1905 paper on special relativity. That work also displays a passion for unity in science characteristic of nearly all his physical thinking, and that may relate to the monism of Spinoza, a philosopher whom he read and reread. Einstein's own understanding of relativity stressed the invariance of the space-time interval and promoted realism with regard to the structure of space-time. Realism also shows up in Einstein's work on Brownian motion (1905), which was explicitly motivated by his long-standing interest in demonstrating the reality of molecules (and atoms), and in the realist treatment of light quanta in his analysis (1905) of the photoelectric effect. While he pioneered the development of statistical physics, especially in his seminal investigations of quantum phenomena (1905–25), he never broke with his belief in determinism as the only truly fundamental approach to physical processes. Here again one sees an affinity with Spinoza. Realism and determinism brought Einstein into conflict with the new quantum theory (1925–26), whose observer dependence and "flight into statistics" convinced him that it could not constitute genuinely fundamental physics. Although influential in its development, he became the theory's foremost critic, never contributing to its refinement but turning instead to the program of unifying the electromagnetic and gravitational fields into one grand, deterministic synthesis that would somehow make room for quantum effects as limiting or singular cases. It is generally agreed that his unified field program was not successful, although his vision continues to inspire other unification programs, and his critical assessments of quantum mechanics still challenge the instrumentalism associated with the theory.

Einstein's philosophical reflections constitute an important chapter in twentieth-century thought. He understood realism as less a metaphysical doctrine than a motivational program, and he argued that determinism was a feature of theories rather than an aspect of the world directly. Along with the unity of science, other central themes in his thinking include his rejection of inductivism and his espousal of holism and constructivism (or conventionalism), emphasizing that meanings, concepts, and theories are free creations, not logically derivable from experience but subject rather to overall criteria of comprehensibility, empirical adequacy, and logical simplicity. Holism is also apparent in his acute analysis of the testability of geometry and his rejection of Poincaré's geometric conventionalism.

Eleatic School, strictly, two fifth-century B.C. Greek philosophers, Parmenides and Zeno of Elea. (The Ionian Greek colony of Elea or Hyele in southern Italy became Velia in Roman times and retains that name today.) A playful remark by Plato in *Sophist* 242d gave rise to the notion that Xenophanes of Colophon, who was active in southern Italy and Sicily, was Parmenides' teacher, had anticipated Parmenides' views, and founded the Eleatic School. Moreover, Melissus of Samos and (according to some ancient sources) even the atomist philosopher Leucippus of Abdera came to be regarded as "Eleatics," in the sense of sharing fundamental views with Parmenides and Zeno. In the broad and traditional use of the term, the Eleatic School characteristically holds that "all is one" and that change and plurality are unreal. So stated, the School's position is represented best by Melissus. **See also** **MELISSUS OF SAMOS, PARMENIDES, XENOPHANES.** A.P.D.M.

elenchus, a cross-examination or refutation. Typically in Plato's early dialogues, Socrates has a conversation with someone who claims to have some sort of knowledge, and Socrates refutes this claim by showing the interlocutor that what he thinks he knows is inconsistent with his other opinions. This refutation is called an elenchus. It is not entirely negative, for awareness of his own ignorance is supposed to spur the interlocutor to further inquiry, and the concepts and assumptions employed in the refutations serve as the basis for positive Platonic treatments of the same topic. In contrast, sophistic elenchi are merely eristic: they aim simply at the refutation of an opponent by any means. Thus, Aristotle calls fallacies that only appear to be refutations "sophistical elenchi." **See also** **SOCRATES.** E.C.H.

Elizabeth of Bohemia (1618–80), German Princess whose philosophical reputation rests on her correspondence with Descartes. The most heavily discussed portion of this correspondence focuses on the relationship between the mind and the body and on Descartes's claim that the mind-body union is a simple notion. Her discussions of free will and of the nature of the sovereign good also have philosophical interest. **See also** **DESCARTES, PHILOSOPHY OF MIND.** M.At.

ellipsis, an expression (spoken or written) from which semantically or syntactically essential material has been deleted, usually for conciseness. Elliptical sentences are often used to answer questions without repeating material occurring in the questions. For example, the word 'Lincoln' may be an answer to the question of the authorship of the Gettysburg Address or to the question of the birthplace of George Boole. The single word 'Lincoln' can be seen as an elliptical name when used as an ellipsis of 'Abraham Lincoln', and as an elliptical sentence when used as an ellipsis for 'Abraham Lincoln wrote the Gettysburg Address'. Other typical elliptical sentences are: 'Abe is a father of two [children]', 'Ben arrives at twelve [noon]'. A typical ellipsis that occurs in discussion of ellipses involves citing the elliptical sentences with the deleted material added in brackets (often with 'sc' or '*scilicet*') instead of also presenting the complete sentence. Ellipsis also occurs above the sentential level, e.g. where well-known premises are omitted in argumentation. The word 'enthymeme' designates an elliptical argument expression from which a premise-expression or even conclusion-expression is absent. The expression 'elliptic ambiguity' designates ambiguity arising from ellipsis. **See also** **AMBIGUITY, ARGUMENT, ENTHYMEME, LOGICAL FORM.** J.Cor.

emanationism, a doctrine about the origin and ontological structure of the world, most frequently associated with Plotinus and other Neoplatonists, according to which everything else that exists is an emanation from a primordial unity called by Plotinus "the One." The first product of emanation from the One is Intelligence (*noûs*), a realm resembling Plato's world of Forms. From Intelligence emanates Soul (*psuchē*), conceived as an active principle that imposes, insofar as that is possible, the rational structure of Intelligence on the matter that emanates from Soul. The process of emanation is typically conceived to be necessary and timeless: although Soul, for instance, proceeds from Intelligence, the notion of procession is one of logical dependence rather than temporal sequence. The One remains unaffected and undiminished by emanation: Plotinus likens the One to the sun, which necessarily emits light from its naturally infinite abundance without suffering change or loss of its own substance. Although emanationism influenced some Jewish, Christian, and Islamic thinkers, it was incompatible with those theistic doctrines of divine activity that maintained that God's creative choice and the world thus created were contingent, and that God can, if he chooses, interact directly with individual creatures. **See also** PLOTINUS. W.E.M.

embodiment, the bodily aspects of human subjectivity. Embodiment is the central theme in European phenomenology, with its most extensive treatment in the works of Maurice Merleau-Ponty. Merleau-Ponty's account of embodiment distinguishes between "the objective body," which is the body regarded as a physiological entity, and "the phenomenal body," which is not just *some* body, some particular physiological entity, but *my* (or your) body as I (or you) experience it. Of course, it is possible to experience one's own body as a physiological entity. But this is not typically the case. Typically, I experience my body (tacitly) as a unified potential or capacity for doing this and that – typing this sentence, scratching that itch, etc. Moreover, this sense that I have of my own motor capacities (expressed, say, as a kind of bodily confidence) does not depend on an understanding of the physiological processes involved in performing the action in question. The distinction between the objective and phenomenal body is central to understanding the phenomenological treatment of embodiment. Embodiment is not a concept that pertains to the body grasped as a physiological entity. Rather it pertains to the phenomenal body and to the role it plays in our object-directed experiences. **See also** MERLEAU-PONTY, PHENOMENOLOGY. D.Le.

Emerson, Ralph Waldo (1803–82), American philosophical essayist, lecturer, and poet, a leading figure in the transcendentalist movement. He was born in Boston and educated at Harvard. As a young man he taught school and served as a Unitarian minister (1826–32). After he resigned his pastorate in 1832, he traveled to Europe to visit Coleridge, Carlyle, and Wordsworth. Upon his return, he settled in Concord, Massachusetts, and began anew as a public lecturer, essayist, and cultural critic. All the while he maintained a voluminous correspondence and kept a detailed, evocative journal. Most of this material has been published, and it casts considerable light on the depth of his thought, at times more so than do his public presentations and books.

His life was pockmarked by personal tragedies, notably the death of his father when Emerson was eight; the death of his first wife, Ellen, after two years of marriage; and the death of his oldest son, Waldo, at the age of five. Such afflictions belie the commonly held assumption that Emerson was a thinker who did not face the intractable problem of evil. To the contrary, his writings should be read as a continuing struggle to render the richest possible version of our situation, given that "things are in the saddle and ride mankind." Although Emerson did not write a systematic work in philosophy, he unquestionably bequeathed an important philosophical vision and countless philosophical pieces. Beginning with his concentration on the motif of nature, its embracing quality, and the rhythms of our inextricable presence within its activities, Emerson details the "compensatory" ebb and flow of the human journey. The human soul and nature are related as "print" to "seal," and yet nature is not always beneficent. In his "Compensation," Emerson writes that "the value of the universe continues to throw itself into every point. If the good is there, so is the evil; if the affinity, so the repulsion; if the force, so the limitation." After the acclaim given the publication of Emerson's first book, *Nature* (1836), he began to gather his public lectures, a medium in which he was riveting, convincing, and inspiring. In 1841 Emerson published his *Essays – First Series*, which included the lovely "Circles," wherein he follows the blunt maxim "We grizzle every day" with the healing affirmation that "life is a series of surprises." This volume also contains "Self-Reliance," which furnished a motto for the self-proclaiming intrepidity of nineteenth-century American individualism. The enthusiastic response to Emerson's essays enabled him to publish three additional collections within the decade: *Essays – Second Series* (1844), *Nature, Addresses and Lectures* (1849), and *Representative Men* (1850). These books and their successors contained lectures, orations, poems, and addresses over a wide range of topics, philosophical, personal, characterological, travel, historical, and literary. Emerson's prose is swift, clear, and epigrammatic, like a series of written stochastic probes, resulting in a Yankee crazy quilt, munificent of shape and color. Emerson spoke to be heard and wrote to be read, especially by the often denigrated "common" person. In fact, during Emerson's European lecture tour in 1848, a letter to a London newspaper requested lowering the admission price so that poorer people could attend, for "to miss him is to lose an important part of the Nineteenth Century."

Emerson's deeply democratic attitude had a reflective philosophical base. He believed that ordinary experience was epiphanic if we but open ourselves to its virtually infinite messages. Despite his Brahmanic appearance and demeanor, Emerson was in continuous touch with ordinary things. He wrote, "Our chief experiences have been casual." His belief in the explosive and pedagogical character of ordinary experience is especially present in his influential oration "The American Scholar." After criticizing American thought as thoroughly derivative, he plots the influences necessary to generate a genuine scholar, paramount among them nature and the learning of the past, though he cautions us not to be trapped in excessive retrospection at the expense of "an original relation to the universe." It is his discussion of "action" as the third influence on the scholar that enables him to project his clearest statement of his underlying philosophical commitment. Without action, "thought can never ripen into truth"; moreover, "thinking is a partial act," whereas living is a "total act." Expressly opposed to any form of psychological, religious, philosophical, or behavioral dualism, he counsels us that the spiritual is not set apart, beyond reach of those who toil in the everyday. Rather, the most profound meanings of the human condition "lurk" in the "common," the "low," the "familiar," the "today."

The influence of the thought of Emerson reaches across class, caste, genre, and persuasion. Thinkers as diverse as James, Nietzsche, Whitman, Proust, Gertrude Stein, Robert Frost, Frank Lloyd Wright, Frederick Law Olmsted, and Wallace Stevens are among those deeply indebted to Emerson. Yet it was Dewey who best caught the enduring bequest of Emerson, writing of "the final word of Emerson's philosophy, [as] the identity of Being, unqualified and immutable, with character."

Emersonian perfectionism. See CAVELL.

emotion, as conceived by philosophers and psychologists, any of several general types of mental states, approximately those that had been called "passions" by earlier philosophers, such as Descartes and Hume. Anger, e.g., is one emotion, fear a second, and joy a third. An emotion may also be content-specific, e.g. fear of an earthquake, or a token of an emotion type, e.g. Mary's present fear that an earthquake is imminent.

The various states typically classified as emotions appear to be linked together only by overlapping family resemblances rather than by a set of necessary and sufficient conditions. Thus an adequate philosophical or psychological "theory of emotion" should probably be a *family* of theories. Even to label these states "emotions" wrongly suggests that they are all marked by *emotion*, in the older sense of mental agitation (a metaphorical extension of the original sense, agitated motion). A person who is, e.g., pleased or sad about something is not typically agitated. To speak of anger, fear, joy, sadness, etc., collectively as "the emotions" fosters the assumption (which James said he took for granted) that these are just qualitatively distinct *feelings of mental agitation*. This exaggerates the importance of agitation and neglects the characteristic differences, noted by Aristotle, Spinoza, and others, in the types of situations that evoke the various emotions.

One important feature of most emotions is captured by the older category of passions, in the sense of 'ways of being acted upon'. In many languages nearly all emotion adjectives are derived from participles: e.g., the English words 'amused', 'annoyed', 'ashamed', 'astonished', 'delighted', 'embarrassed', 'excited', 'frightened', 'horrified', 'irritated', 'pleased', 'terrified', 'surprised', 'upset', and 'worried'. When we are, e.g., embarrassed, something acts on us, i.e. *embarrasses* us: typically, some situation or fact of which we are aware, such as our having on unmatched shoes. To call embarrassment a passion in the sense of a way of being acted upon does not imply that we are "passive" with respect to it, i.e. have no control over whether a given situation embarrasses us and thus no responsibility for our embarrassment.

Not only situations and facts but also *persons* may "do" something to us, as in love and hate, and mere *possibilities* may have an effect on us, as in fear and hope. The possibility emotions are sometimes characterized as "forward-looking," and emotions that are responses to actual situations or facts are said to be "backward-looking." These temporal characterizations are inaccurate and misleading. One may be fearful or hopeful that a certain event occurred in the past, provided one is not certain as to whether it occurred; and one may be, e.g., embarrassed about what is going to occur, provided one is certain it will occur.

In various passions the effect on us may include involuntary physiological changes, feelings of agitation due to arousal of the autonomic nervous system, characteristic facial expressions, and inclinations toward intentional action (or inaction) that arise independently of any rational warrant. Phenomenologically, however, these effects do not appear to us to be alien and nonrational, like muscular spasms. Rather they seem an integral part of our perception of the situation as, e.g., an embarrassing situation or one that warrants our embarrassment.

emotions, the seven. See KOREAN PHILOSOPHY.

emotions, the six. See QING.

emotive conjugation, a humorous verbal conjugation, designed to expose and mock first-person bias, in which ostensibly the same action is described in successively more pejorative terms through the first, second, and third persons (e.g., 'I am firm, You are stubborn, He is a pig-headed fool'). This example was used by Russell in the course of a BBC Radio "Brains' Trust" discussion in 1948. It was popularized later that year when the *New Statesman* ran a competition for other examples. An "unprecedented response" brought in 2,000 entries, including: "I am well informed, You listen to gossip, He believes what he reads in the paper"; and "I went to Oxford, You went to Cambridge, He went to the London School of Economics" (Russell was educated at Cambridge and later taught there). **See also** RUSSELL. N.G.

emotive meaning. See EMOTIVISM, MEANING.

emotivism, a noncognitivist metaethical view opposed to cognitivism, which holds that moral judgments should be construed as assertions about the moral properties of actions, persons, policies, and other objects of moral assessment, that moral predicates purport to refer to properties of such objects, that moral judgments (or the propositions that they express) can be true or false, and that cognizers can have the cognitive attitude of belief toward the propositions that moral judgments express. Noncognitivism denies these claims; it holds that moral judgments do not make assertions or express propositions. If moral judgments do not express propositions, the former can be neither true nor false, and moral belief and moral knowledge are not possible. The emotivist is a noncognitivist who claims that moral judgments, in their primary sense, express the appraiser's attitudes – approval or disapproval – toward the object of evaluation, rather than make assertions about the properties of that object.

Because emotivism treats moral judgments as the expressions of the appraiser's pro and con attitudes, it is sometimes referred to as the *boo-hurrah theory* of ethics. Emotivists distinguish their thesis that moral judgments express the appraiser's attitudes from the subjectivist claim that they state or report the appraiser's attitudes (the latter view is a form of cognitivism). Some versions of emotivism distinguish between this primary, emotive meaning of moral judgments and a secondary, descriptive meaning. In its primary, emotive meaning, a moral judgment expresses the appraiser's attitudes toward the object of evaluation rather than ascribing properties to that object. But secondarily, moral judgments refer to those non-moral properties of the object of evaluation in virtue of which the appraiser has and expresses her attitudes. So if I judge that your act of torture is wrong, my judgment has two components. Its primary, emotive sense is to express my disapproval of your act. Its secondary descriptive sense is to denote those non-moral properties of your act upon which I base my disapproval. These are presumably the very properties that make it an act of torture – roughly, a causing of intense pain in order to punish, coerce, or afford sadistic pleasure.

By making emotive meaning primary, emotivists claim to preserve the univocity of moral language between speakers who employ different criteria of application for their moral terms. Also, by stressing the intimate connection between moral judgment and the agent's non-cognitive attitudes, emotivists claim to capture the motivational properties of moral judgment. Some emotivists have also attempted to account for ascriptions of truth to moral judgments by accepting the redundancy account of ascriptions of truth as expressions of agreement with the original judgment. The emotivist must think that such ascriptions of truth to moral judgments merely reflect the ascriber's agreement in noncognitive attitude with the attitude expressed by the original judgment.

Critics of emotivism challenge these alleged virtues. They claim that moral agreement need not track agreement in attitude; there can be moral disagreement without disagreement in attitude (between moralists with different moral views), and disagreement in attitude without moral disagreement (between moralists and immoralists). By distinguishing between the meaning of moral terms and speakers' beliefs about the extension of those terms, critics claim that we can account for the univocity of moral terms in spite of moral disagreement without introducing a primary emotive sense for moral terms. Critics also allege that the emotivist analysis of moral judgments as the expression of the appraiser's attitudes precludes recognizing the possibility of moral judgments that do not engage or reflect the attitudes of the appraiser. For instance, it is not clear how emotivism can accommodate the amoralist – one who recognizes moral requirements but is indifferent to them. Critics also charge emotivism with failure to capture the cognitive aspects of moral discourse. Because emotivism is a theory about moral judgment or assertion, it is difficult for the emotivist to give a semantic analysis of moral predicates in unasserted contexts, such as in the antecedents of conditional moral judgments (e.g., 'If he did *wrong*, then he ought to be punished'). Finally, one might want to recognize the *truth* of some moral judgments, perhaps in order to make room for the possibility of moral mistakes. If so, then one may not be satisfied with the emotivist's appeal to redundancy or disquotational accounts of the *ascription of truth*.

Emotivism was introduced by Ayer in *Language, Truth, and Logic* (2d ed., 1946) and refined by C. L. Stevenson in *Facts and Values* (1963) and *Ethics and Language* (1944).

See also ETHICAL OBJECTIVISM, FREGE-GEACH PROBLEM, METAETHICS, MORAL SKEPTICISM, NIHILISM, PRESCRIPTIVISM. D.O.B.

empathic solipsism. See SOLIPSISM.

empathy, imaginative projection into another person's situation, especially for vicarious capture of its emotional and motivational qualities. The term is an English rendering (by the Anglo-American psychologist E. G. Titchener, 1867–1927) of the German *Einfühlung*, made popular by Theodore Lipps (1851–1914), which also covered imaginative identification with inanimate objects of aesthetic contemplation. Under 'sympathy', many aspects were earlier discussed by Hume, Adam Smith, and other Scottish philosophers. Empathy has been considered a precondition of ethical thinking and a major contributor to social bonding and altruism, mental state attribution, language use, and translation.

The relevant spectrum of phenomena includes automatic and often subliminal motor mimicry of the expressions or manifestations of another's real or feigned emotion, pain, or pleasure; emotional contagion, by which one "catches" another's apparent emotion, often unconsciously and without reference to its cause or "object"; conscious and unconscious mimicry of direction of gaze, with consequent transfer of attention from the other's response to its cause; and conscious or unconscious role-taking, which reconstructs in imagination (with or without imagery) aspects of the other's situation as the other "perceives" it.

Empedocles (c.495–c.435 B.C.), Greek pre-Socratic philosopher who created a physical theory in response to Parmenides while incorporating Pythagorean ideas of the soul into his philosophy. Following Parmenides in his rejection of coming-to-be and perishing, he accounted for phenomenal change by positing four elements (his "roots," *rizomata*), earth, water, air, and fire. When they mix together in set proportions they create compound substances such as blood and bone. Two forces act on the elements, Love and Strife, the former joining the different elements, the latter separating them. In his cyclical cosmogony the four elements combine to form the Sphere, a completely homogeneous spherical body permeated by Love, which, shattered by Strife, grows into a cosmos with the elements forming distinct cosmic masses of earth, water (the seas), air, and fire. There is controversy over whether Empedocles posits one or two periods when living things exist in the cycle. (On one view there are two periods, between which intervenes a stage of complete separation of the elements.) Empedocles accepts the Pythagorean view of reincarnation of souls, seeing life as punishment for an original sin and requiring the expiation of a pious and philosophical life. Thus the exile and return of the individual soul reflect in the microcosm the cosmic movement from harmony to division to harmony. Empedocles' four elements became standard in natural philosophy down to the early modern era, and Aristotle recognized his Love and Strife as an early expression of the efficient cause. **See also** PYTHAGORAS. D.W.G.

empirical. See A PRIORI.

empirical adequacy, a property that a theory has when it correctly represents the observable phenomena. Empirical adequacy is readily understandable in relation to truth, by means of a distinction between observable and unobservable entities. If the truth of a theory consists in its corresponding to both the observable and unobservable aspects of reality, empirical adequacy implies only correspondence with the actual observable phenomena. Thus, any true theory is empirically adequate. But the converse does not hold: a theory might save the observable phenomena while positing unobservable entities that turn out not to exist. On a semantic view of theories, which permits a more rigorous definition, a theory is empirically adequate if and only if the empirical substructure of at least one of its models is isomorphic to a data model of all appearances. Empirical adequacy is central to van Fraassen's constructive empiricism, which takes appearances to include not just the available data, but all actual observable phenomena, past, present, and future. Although most of even our best current theories fall short of this demanding ideal in some recognizable respects, empirical adequacy is among the rock-bottom criteria by which to gauge the success of a scientific theory. **See also** CONSTRUCTIVE EMPIRICISM, PHILOSOPHY OF SCIENCE. D.J.M.

empirical decision theory, the scientific study of human judgment and decision making. A growing body of empirical research has described the actual limitations on inductive reasoning. By contrast, traditional decision theory is normative; the theory proposes ideal procedures for solving some class of problems. The descriptive study of decision making was pioneered by figures including Amos Tversky, Daniel Kahneman, Richard Nisbett, and Lee Ross, and their empirical research has documented the limitations and biases of various heuristics, or simple rules of thumb, routinely used in reasoning. The representativeness heuristic is a rule of thumb used to judge probabilities based on the degree to which one class represents (or resembles) another class. For example, we assume that basketball players have a "hot hand" during a particular game – producing an uninterrupted string of successful shots – because we underestimate the relative frequency with which such successful runs occur in the entire population of that player's record. The availability heuristic is a rule of thumb that uses the ease with which an instance comes to mind as an index of the probability of an event. Such a rule is unreliable when salience in memory misleads; for example, most people (incorrectly) rate death by shark attack as more probable than death by falling airplane parts. (For an overview, see D. Kahneman, P. Slovic, and A. Tversky, eds., *Judgment Under Uncertainty: Heuristics and Biases*, 1982.) These biases, found in laypeople and statistical experts alike, have a natural explanation on accounts such as Herbert Simon's (1957) concept of "bounded rationality." According to this view, the limitations on our decision making are fixed in part by specific features of our psychological architecture. This architecture places constraints on such factors as processing speed and information capacity, and this in turn produces predictable, systematic errors in performance. Thus, rather than proposing highly idealized rules appropriate to an omniscient Laplacean genius – more characteristic of traditional normative approaches to decision theory – empirical decision theory attempts to formulate a descriptively accurate, and thus psychologically realistic, account of rationality. Even if certain simple rules can, in particular settings, outperform other strategies, it is still important to understand the causes of the systematic errors we make on tasks perfectly representative of routine decision making. Once the context is specified, empirical decision-making research allows us to study both descriptive decision rules that we follow spontaneously and normative rules that we ought to follow upon reflection. **See also** BAYESIAN RATIONALITY, DECISION THEORY, HEURISTICS. J.D.T.

empirical ego. See KANT.

empirical meaning. See MEANING.

empirical probability. See PROBABILITY.

empiricism (from *empiric*, 'doctor who relies on practical experience', ultimately from Greek *empeiria*, 'experience'), a type of theory in epistemology, the basic idea behind all examples of the type being that experience has primacy in human knowledge and justified belief. Because empiricism is not a single view but a type of view with many different exemplifications, we should speak not just of empiricism but of empiricism*s*. Perhaps the most fundamental distinction among the various empiricisms is that between those consisting of some claim about concepts and those consisting of some claim about beliefs – call these, respectively, *concept-empiricisms* and *belief-empiricisms*.

Concept-empiricisms all begin by singling out those concepts that apply to some experience or other; the concept of dizziness, e.g., applies to the experience of dizziness. And what is then claimed is that all concepts that human beings do and can possess either apply to some experience that someone has had, or have been derived from such concepts by someone's performing on those concepts one or another such mental operation as combination, distinction, and abstraction. How exactly *my* concepts must be related to *my* experience and to *my* performance of those mental operations are matters on which concept-empiricists differ; most if not all would grant we each acquire many concepts by learning language, and it does not seem plausible to hold that each concept thus acquired either applies to some experience that one has oneself had or has been derived from such by oneself. But though concept-empiricists disagree concerning the conditions for linguistic acquisition or transmission of a concept, what unites them is the claim that either all human concepts apply to some actual experience or they have been derived from such by someone's performing on an actual experience the mental operations of combination, distinction, and abstraction. Most concept-empiricists will also say something more: that the experience must have *evoked* the concept in the person having it, or that the person having it must have *recognized* that the concept applies to his or her experience, or something of that sort.

What unites all *belief*-empiricists is the claim that for beliefs to possess any truth-relevant merit, they must be related in one or another way to someone's experience. Belief-empiricisms differ from each other, for one thing, with respect to the merit concerning which the claim is made. Some belief-empiricists claim that a belief does not have the status of *knowledge* unless it has the requisite relation to experience; some claim that a belief lacks *warrant* unless it has that relation; others claim that a belief is not *permissibly held* unless it stands in that relation; and yet others claim that it is not a *properly scientific* belief unless it stands in that relation. And not even this list exhausts the possibilities. Belief-empiricisms also differ with respect to the specific relation to experience that is said to be necessary for the merit in question to be present. Some belief-empiricists hold, e.g., that a belief is permissibly held only if either its propositional content is a report of the person's present or remembered experience, or the belief is held on the basis of such beliefs and is probable with respect to the beliefs on the basis of which it is held. Kant, by contrast, held the rather different view that if a belief is to constitute (empirical) *knowledge*, it must in some way *be about* experience. Third, belief-empiricisms differ from each other with respect to the person to whose experience a belief must stand in the relation specified if it is to possess the merit specified. It need not always be an experience of the person whose belief is being considered. It might be an experience of someone giving testimony about it. Clearly, a philosopher might accept one kind of empiricism while rejecting others. Thus to ask philosophers whether they are empiricists is a question void for vagueness. It is regularly said of Locke that he was an empiricist; and indeed, he was a concept-empiricist of a certain sort. But he embraced no version whatsoever of belief-empiricism.

So far, 'experience' has been used without explanation. But anyone acquainted with the history of philosophy will be aware that for different philosophers the word picks out different phenomena; and even when they use it to designate the same phenomenon, they differ regarding the structure of what they call 'experience.' The differences on these matters reflect yet more distinctions among empiricisms than have been delineated above.

enantiamorphs (from Greek *enantios*, 'opposite', and *morphe*, 'form'), objects whose shapes differ as do those of a right and left hand. One of a pair of enantiamorphs can be made to look identical in shape to the other by viewing it in a mirror but not merely by changing its spatial orientation. Enantiamorphs figure prominently in the work of Kant, who argued that the existence of enantiamorphic pairs entailed that Leibnizian relational theories of space were to be rejected in favor of Newtonian absolutist theories, that some facts about space could be apprehended only by "pure intuition," and that space was mind-dependent. **See also** **KANT**, **LEIBNIZ**. encratic. See ARISTOTLE.

***Encyclopedia*,** in French, *Encyclopédie;* full English title: *Encyclopedia, or a Descriptive Dictionary of the Sciences, Arts and Trades*. Launched in 1747 by the Parisian publisher Le Breton, who had secured d'Alembert's and Diderot's editorship, the *Encyclopedia* was gradually released from 1751 to 1772, despite a temporary revocation of its royal privilege. Comprising seventeen folio volumes of 17,818 articles and eleven folio volumes of 2,885 plates, the work required a staff of 272 contributors, writers, and engravers. It incorporated the accumulated knowledge and rationalist, secularist views of the French Enlightenment and prescribed economic, social, and political reforms. Enormously successful, the work was reprinted with revisions five times before 1789. Contributions were made by the *philosophes* Voltaire, Rousseau, Montesquieu, d'Holbach, Naigeon, and Saint-Lambert; the writers Duclos and Marmontel; the theologians Morellet and Malet; enlightened clerics, e.g. Raynal; explorers, e.g. La Condamine; natural scientists, e.g. Daubenton; physicians, e.g. Bouillet; the economists Turgot and Quesnay; engineers, e.g. Perronet; horologists, e.g. Berthoud; and scores of other experts.

"The purpose of an Encyclopedia," wrote Diderot, "is to collect the knowledge dispersed on the surface of the earth, and to unfold its general system" (*Encyclopedia*, Vol. 5, 1755). The *Encyclopedia* offered the educated reader a comprehensive, systematic, and descriptive repository of contemporary liberal and mechanical arts. D'Alembert and Diderot developed a sensationalist epistemology ("Preliminary Discourse") under the influence of Locke and Condillac. They compiled and rationally classified existing knowledge according to the noetic process (memory, imagination, and reason). Based on the assumption of the unity of theory and praxis, their approach was positivistic and utilitarian.

The Encyclopedists vindicated experimental reason and the rule of nature, fostered the practice of criticism, and stimulated the development of new sciences. In religious matters, they cultivated ambiguity to escape censorship. Whereas most contributors held either conciliatory or orthodox positions, d'Alembert, Diderot, and d'Holbach barely concealed their naturalistic and atheistic opinions. Their radicalism was pervasive. Supernaturalism, obscurantism, and fanaticism were among the Encyclopedists' favorite targets. They identified religion with superstition and theology with black magic; asserted the superiority of natural morality over theological ethics; demanded religious toleration; and championed human rights. They innovatively retraced the historical conditions of the development of modern philosophy. They furthermore pioneered ideas on trade and industry and anticipated the relevance of historiography, sociology, economics, and linguistics. As the most ambitious and expansive reference work of its time, the *Encyclopedia* crystallized the confidence of the eighteenth-century bourgeoisie in the capacity of reason to dispel the shadows of ignorance and improve society.

***energeia*,** Greek term coined by Aristotle and often translated as 'activity', 'actuality', and even 'act', but more literally rendered '(a state of) functioning'. Since for Aristotle the function of an object is its *telos*, or aim, *energeia* can also be described as an *entelecheia*, or realization (another coined term he uses interchangeably with *energeia*). So understood, it can denote either (a) something's being functional, though not in use at the moment, or (b) something's actually functioning, which Aristotle describes as a "first realization" and "second realization" respectively (*On the Soul* II.5). In general, every *energeia* is correlative to some *dunamis*, a capability or power to function in a certain way, and in the central books of the *Metaphysics* Aristotle uses the linkage between these two concepts to explain the relation of form to matter. He also distinguishes between *energeia* and *kinēsis* (change or motion) (*Metaphysics* IX.6; *Nicomachean Ethics* X.4). A *kinēsis* is defined by reference to its terminus (e.g., learning *how to multiply*) and is thus incomplete at any point before reaching its conclusion. An *energeia*, in contrast, is a state complete in itself (e.g., seeing). Thus, Aristotle says that at any time that I am seeing, it is also true that I have seen; but it is not true that at any time I am learning that I have learned. In Greek, this difference is not so much one of tense as of aspect: the perfect tense marks a "perfect" or complete state, and not necessarily prior activity. **See also** ARISTOTLE. V.C.

energeticism, also called energetism or energism, the doctrine that energy is the fundamental substance underlying all change. Its most prominent champion was the physical chemist Wilhelm Ostwald (1853–1932). In his address "Die Überwindung des wissenschaftlichen Materialismus" ("The Conquest of Scientific Materialism"), delivered at Lübeck in 1895, Ostwald chastised the atomic-kinetic theory as lacking progress and claimed that a unified science, energetics, could be based solely on the concept of energy. Many of Ostwald's criticisms of materialism and mechanistic reductionism derived from Mach. Ostwald's attempts to deduce the fundamental equations of thermodynamics and mechanics from the principles of energy conservation and transformation were indebted to the writings of Georg Helm (1874–1919), especially *Die Lehre von Energie* ("The Laws of Energy," 1887) and *Die Energetik* ("Energetics," 1898). Ostwald defended Helm's factorization thesis that all changes in energy can be analyzed as a product of intensity and capacity factors. The factorization thesis and the attempt to derive mechanics and thermodynamics from the principles of energetics were subjected to devastating criticisms by Boltzmann and Max Planck. Boltzmann also criticized the dogmatism of Ostwald's rejection of the atomic-kinetic theory. Ostwald's program to unify the sciences under the banner of energetics withered in the face of these criticisms. **See also** BOLTZMANN, MACH, PHILOSOPHY OF SCIENCE. M.C.

energetism, energism. See ENERGETICISM.

Engels, Friedrich (1820–95), German socialist and economist who, with Marx, founded Marxism. Whether there are significant differences between Marx and Engels is much disputed by scholars of Marxism. Certainly there are differences in emphasis, but there was also a division of labor between them. Engels, and not Marx, presented a Marxist account of natural science and integrated Darwinian elements in Marxian theory. But they also coauthored major works, including *The Holy Family*, *The German Ideology* (1845), and *The Communist Manifesto* (1848). Engels considered himself the junior partner in their lifelong collaboration. That judgment is correct, but Engels's work is both significant and more accessible than Marx's. He gave popular articulations of their common views in such books as *Socialism: Utopian and Scientific* and *Anti-Dühring* (1878). His work, more than Marx's, was taken by the Second International and many later Marxist militants to be definitive of Marxism. Only much later with some Western Marxist theoreticians did his influence decline.

Engels's first major work, *The Condition of the Working Class in England* (1845), vividly depicted workers' lives, misery, and systematic exploitation. But he also saw the working class as a new force created by the industrial revolution, and he developed an account of how this new force would lead to the revolutionary transformation of society, including collective ownership and control of the means of production and a rational ordering of social life; all this would supersede the waste and disparity of human conditions that he took to be inescapable under capitalism. *The German Ideology*, jointly authored with Marx, first articulated what was later called historical materialism, a conception central to Marxist theory. It is the view that the economic structure of society is the foundation of society; as the productive forces develop, the economic structure changes and with that political, legal, moral, religious, and philosophical ideas change accordingly. Until the consolidation of socialism, societies are divided into antagonistic classes, a person's class being determined by her relationship to the means of production. The dominant ideas of a society will be strongly conditioned by the economic structure of the society and serve the class interests of the dominant class. The social consciousness (the ruling ideology) will be that which answers to the interests of the dominant class.

From the 1850s on, Engels took an increasing interest in connecting historical materialism with natural science. This work took definitive form in his *Anti-Dühring*, the first general account of Marxism, and in his posthumously published *Dialectics of Nature*. (*Anti-Dühring* also contains his most extensive discussion of morality.) It was in these works that Engels articulated the dialectical method and a systematic communist worldview that sought to establish that there were not only social laws expressing empirical regularities in society but also universal laws of nature and thought. These dialectical laws, Engels believed, reveal that both nature and society are in a continuous process of evolutionary though conflict-laden development.

Engels should not be considered primarily, if at all, a speculative philosopher. Like Marx, he was critical of and ironical about speculative philosophy and was a central figure in the socialist movement. While always concerned that his account be warrantedly assertible, Engels sought to make it not only true, but also a finely tuned instrument of working-class emancipation which would lead to a world without classes.

K.N.

Enlightenment, the, a late eighteenth-century international movement in thought, with important social and political ramifications. The Enlightenment is at once a style, an attitude, and a temper – critical, secular, skeptical, empirical, and practical. It is also characterized by core beliefs in human rationality, in what it took to be "nature," and in the "natural feelings" of mankind. Four of its most prominent exemplars are Hume, Thomas Jefferson, Kant, and Voltaire.

The Enlightenment belief in human rationality had several aspects. (1) Human beings are free to the extent that their actions are carried out for a reason. Actions prompted by traditional authority, whether religious or political, are therefore not free; liberation requires weakening if not also overthrowing this authority. (2) Human rationality is universal, requiring only education for its development. In virtue of their common rationality, all human beings have certain rights, among them the right to choose and shape their individual destinies. (3) A final aspect of the belief in human rationality was that the true forms of all things could be discovered, whether of the universe (Newton's laws), of the mind (associationist psychology), of good government (the U.S. Constitution), of a happy life (which, like good government, was "balanced"), or of beautiful architecture (Palladio's principles). The Enlightenment was preeminently a "formalist" age, and prose, not poetry, was its primary means of expression.

The Enlightenment thought of itself as a return to the classical ideas of the Greeks and (more especially) the Romans. But in fact it provided one source of the revolutions that shook Europe and America at the end of the eighteenth century, and it laid the intellectual foundations for both the generally scientific worldview and the liberal democratic society, which, despite the many attacks made on them, continue to function as cultural ideals.

G.G.B.

ens a se (Latin, 'a being from itself'), a being that is completely independent and self-sufficient. Since every creature depends at least upon God for its existence, only God could be *ens a se*. In fact, only God is, and he must be. For if God depended on any other being, he would be dependent and hence not self-sufficient. To the extent that the ontological argument is plausible, it depends on conceiving of God as *ens a se*. In other words, God as *ens a se* is the greatest conceivable being. The idea of *ens a se* is very important in the *Monologion* and *Proslogion* of Anselm, in various works of Duns Scotus, and later Scholastic thought.

Ens a se should be distinguished from *ens ex se*, according to Anselm in *Monologion*. *Ens a se* is from itself and not 'out of itself'. In other words, *ens a se* does not depend upon itself for its own existence, because it is supposed to be dependent on absolutely nothing. Further, if *ens a se* depended upon itself, it would cause itself to exist, and that is impossible, according to medieval and Scholastic philosophers, who took causality to be irreflexive. (It is also transitive and asymmetric.) Hence, the medieval idea of *ens a se* should not be confused with Spinoza's idea of *causa sui*.

Later Scholastics often coined abstract terms to designate the property or entity that makes something to be what it is, in analogy with forming, say, 'rigidity' from 'rigid'. The Latin term '*aseitas*' is formed from the prepositional phrase in '*ens a se*' in this way; '*aseitas*' is translated into English as 'aseity'. A better-known example of forming an abstract noun from a concrete word is '*haecceitas*' (thisness) from '*haec*' (this).

ens ex se. See ENS A SE.

en soi. See SARTRE.

ens per accidens. See PER ACCIDENS.

ens perfectissimo. See ENS REALISSIMUM.

ens rationis (Latin, 'a being of reason'), a thing dependent for its existence upon reason or thought; sometimes known as an intentional being. *Ens rationis* is the contrasting term for a real being (*res* or *ens in re extra animam*), such as an individual animal. Real beings exist independently of thought and are the foundation for truth. A being of reason depends upon thought or reason for its existence and is an invention of the mind, even if it has a foundation in some real being. (This conception requires the idea that there are degrees of being.) Two kinds of *entia rationis* are distinguished: those with a foundation in reality and those without one. The objects of logic, which include genera and species, e.g. animal and human, respectively, are *entia rationis* that have a foundation in reality, but are abstracted from it. In contrast, mythic and fictional objects, such as a chimera or Pegasus, have no foundation in reality. Blindness and deafness are also sometimes called *entia rationis*. **See also** AQUINAS, SUÁREZ. A.P.M.

ens realissimum (Latin, 'most real being'), an informal term for God that occurs rarely in Scholastic philosophers. Within Kant's philosophy, it has a technical sense. It is an extension of Baumgarten's idea of *ens perfectissimum* (most perfect being), a being that has the greatest number of possible perfections to the greatest degree. Since *ens perfectissimum* refers to God as the sum of all possibilities and since actuality is greater than possibility, according to Kant, the idea of God as the sum of all actualities, i.e. *ens realissimum*, makes the latter a preferable term for God. Kant thinks that human knowledge is "constrained" to posit the idea of a necessary being. The necessary being that has the best claim to necessity is one that is completely unconditioned, i.e. dependent on nothing; this is *ens realissimum*. He sometimes explicates it in three ways: as the substratum of all realities, as the ground of all realities, and as the sum of all realities. *Ens realissimum* is nonetheless empirically invalid, since it cannot be experienced by humans. It is something ideal for reason, not real in experience. According to Kant, the ontological argument begins with the concept of *ens realissimum* and concludes that an existing object falls under that concept (*Critique of Pure Reason*, Book II, Chapter 3). **See also** BAUMGARTEN, KANT. A.P.M.

entailment. See IMPLICATION.

entelechy (from Greek *entelecheia*), actuality. Aristotle, who coined the terms *entelecheia* and *energeia*, treats the former as a near synonym of the latter when it is used in this sense. *Entelecheia* figures in Aristotle's definition of the soul as the first actuality of the natural body (*On the Soul* II.1). This is explained by analogy with knowledge: first actuality is to knowledge as second actuality is to the active use of knowledge.

'Entelechy' is also a technical term in Leibniz for the primitive active force in every monad, which is combined with primary matter and from which the active force, *vis viva*, is somehow derived. The vitalist philosopher Hans Driesch used the Aristotelian term in his account of biology. Life, he held, is an entelechy; and an entelechy is a substantial entity, rather like a mind, that controls organic processes.

See also ENERGEIA, PHILOSOPHY OF BIOLOGY. P.Wo.

enthymeme, an incompletely stated syllogism, with one premise, or even the conclusion, omitted. The term sometimes designates incompletely stated arguments of other kinds. We are expected to supply the missing premise or draw the conclusion if it is not stated. The result is supposed to be a syllogistic inference – e.g., 'He will eventually get caught, for he is a thief'; or 'He will eventually be caught, for all habitual thieves get caught'. This notion of enthymeme as an incompletely stated syllogism has a long tradition and does not seem inconsistent with Aristotle's own characterization of it. Thus, Peter of Spain openly declares that an enthymeme is an argument with a single premise that needs to be "reduced" to a syllogism. But Peter also points out that Aristotle spoke of enthymeme as "being of *ycos* and *signum*," and he explains that *ycos* here means 'probable proposition' while *signum* expresses the necessity of inference. '*P*, therefore *Q*' is an *ycos* in the sense of a proposition that appears to be true to all or to many; but insofar as *P* has virtually a double power, that of itself and of the proposition understood along with it, it is both probable and demonstrative, albeit from a different point of view. **See also** SYLLOGISM. I.Bo.

entrenchment. See GOODMAN.

entropy, in physics, a measure of disorder; in information theory, a measure of "information" in a technical sense. In statistical physics the number of microstates accessible to the various particles of a large system of particles such as a cabbage or the air in a room is represented as Ω. Accessible microstates might be, for instance, energy levels the various particles can reach. One can greatly simplify the statement of certain laws of nature by introducing a logarithmic measure of these accessible microstates. This measure, called entropy, is defined by the formula $S(\text{Entropy}) = df.\ k(\ln \Omega)$, where k is Boltzmann's constant. When the entropy of a system increases, the system becomes more random and disordered, in the sense that a larger number of microstates become available for the system's particles to enter.

If a large physical system within which exchanges of energy occur is isolated, exchanging no energy with its environment, the entropy of the system tends to increase and never decreases. This result of statistical physics is part of the second law of thermodynamics. In real, evolving physical systems effectively isolated from their environments, entropy increases and thus aspects of the system's organization that depend upon there being only a limited range of accessible microstates are altered. For example, a cabbage totally isolated in a container would decay as complicated organic molecules eventually became unstructured in the course of ongoing exchanges of energy and attendant entropy increases.

In information theory, a state or event is said to contain more information than a second state or event if the former state is less probable and thus in a sense more surprising than the latter. Other plausible constraints suggest a logarithmic measure of information content. Suppose X is a set of alternative possible states, x_i, and $p(x_i)$ is the probability of each $x_i \in X$. If state x_i has occurred the information content of that occurrence is taken to be $-\log_2 p(x_i)$. This function increases as the probability of x_i decreases. If it is unknown which x_i will occur, it is reasonable to represent the expected information content of X as the sum of the information contents of the alternative states x_i weighted in each case by the probability of the state, giving

$$-\sum_{x_i \in X} p(x_i) \log_2 p(x_i).$$

This is called the Shannon entropy. Both Shannon entropy and physical entropy can be thought of as logarithmic measures of disarray. But this statement trades on a broad understanding of 'disarray'. A close relationship between the two concepts of entropy should not be assumed. **See also** INFORMATION THEORY, PHILOSOPHY OF SCIENCE. T.H.

envelope paradox, an apparent paradox in decision theory that runs as follows. You are shown two envelopes, M and N, and are reliably informed that each contains some finite positive amount of money, that the amount in one unspecified envelope is twice the amount in the unspecified other, and that you may choose only one. Call the amount in M 'm' and that in N 'n'. It might seem that there is a half chance that $m = 2n$ and a half chance that $m = n/2$, so that the "expected value" of m is $(½)(2n) + (½)(n/2) = 1.25n$, so that you should prefer envelope M. But by similar reasoning it might seem that the expected value of n is $1.25m$, so that you should prefer envelope N. **See also** DECISION THEORY. D.A.J.

environmental ethics. See ENVIRONMENTAL PHILOSOPHY.

environmental philosophy, the critical study of concepts defining relations between human beings and their non-human environment. Environmental ethics, a major component of environmental philosophy, addresses the normative significance of these relations. The relevance of ecological relations to human affairs has been recognized at least since Darwin, but the growing sense of human responsibility for their deterioration, reflected in books such as Rachel Carson's *Silent Spring* (1962) and Singer's *Animal Liberation* (1975), has prompted the recent upsurge of interest.

Environmental philosophers have adduced a wide variety of human attitudes and practices to account for the perceived deterioration, including religious and scientific attitudes, social institutions, and industrial technology. Proposed remedies typically urge a reorientation or new "ethic" that recognizes "intrinsic value" in the natural world. Examples include the "land ethic" of Aldo Leopold (1887–1948), which pictures humans as belonging to, rather than owning, the biotic community ("the land"); deep ecology, a stance articulated by the Norwegian philosopher Arne Naess (b.1912), which advocates forms of identification with the non-human world; and ecofeminism, which rejects prevailing attitudes to the natural world that are perceived as patriarchal.

At the heart of environmental ethics lies the attempt to articulate the basis of concern for the natural world. It encompasses global as well as local issues, and considers the longer-term ecological, and even evolutionary, fate of the human and non-human world. Many of its practitioners question the anthropocentric claim that human beings are the exclusive or even central focus of ethical concern. In thus extending both the scope and the grounds of concern, it presents a challenge to the stance of conventional interhuman ethics. It debates how to balance the claims of present and future, human and non-human, sentient and non-sentient, individuals and wholes. It investigates the prospects for a sustainable relationship between economic and ecological systems, and pursues the implications of this relationship with respect to social justice and political institutions. Besides also engaging metaethical questions about, e.g., the objectivity and commensurability of values, environmental philosophers are led to consider the nature and significance of environmental change and the ontological status of collective entities such as species and ecosystems. In a more traditional vein, environmental philosophy revives metaphysical debates surrounding the perennial question of "man's place in nature," and finds both precedent and inspiration in earlier philosophies and cultures.

See also APPLIED ETHICS, ETHICS, FEMINIST PHILOSOPHY, NATURALISM, VALUE. A.Ho.

epagogē (Greek, 'induction'). Especially in the logic of Aristotle, *epagogē* is opposed to argument by syllogism. Aristotle describes it as "a move from particulars to the universal." For example, premises that the skilled navigator is the best navigator, the skilled charioteer the best charioteer, and the skilled philosopher the best philosopher may support the conclusion by *epagogē* that those skilled in something are usually the best at it. Aristotle thought it more persuasive and clearer than the syllogistic method, since it relies on the senses and is available to all humans. The term was later applied to dialectical arguments intended to trap opponents. R.C.

epicheirema, a polysyllogism in which each premise represents an enthymematic argument – e.g., 'A lie creates disbelief, because it is an assertion that does not correspond to truth; flattery is a lie, because it is a conscious distortion of truth; therefore, flattery creates disbelief'. Each premise constitutes an enthymematic syllogism. Thus, the first premise could be expanded into the following full-fledged syllogism: 'Every assertion that does not correspond to truth creates disbelief; a lie is an assertion that does not correspond to truth; therefore a lie creates disbelief'. We could do likewise with the second premise. Epicheirema can thus be a powerful tool in oral polemics, especially when one argues regressively, first stating the conclusion with a sketch of support in terms of enthymemes, and then – if challenged to do so – expanding any or all of these enthymemes into standard categorical syllogisms. **See also** SYLLOGISM. I.Bo.

Epictetus. See STOICISM.

Epicureanism, one of the three leading movements constituting Hellenistic philosophy. It was founded by Epicurus (341–271 B.C.), together with his close colleagues Metrodorus (c.331–278), Hermarchus (Epicurus's successor as head of the Athenian School), and Polyaenus (d.278). He set up Epicurean communities at Mytilene, Lampsacus, and finally Athens (306 B.C.), where his school, the Garden, became synonymous with Epicureanism. These groups set out to live the ideal Epicurean life, detached from political society without actively opposing it, and devoting themselves to philosophical discussion and the cult of friendship. Their correspondence was anthologized and studied as a model of the philosophical life by later Epicureans, for whom the writings of Epicurus and his three cofounders, known collectively as "the Men," held a virtually biblical status.

Epicurus wrote voluminously, but all that survives are three brief epitomes (the *Letter to Herodotus* on physics, the *Letter to Pythocles* on astronomy, etc., and the *Letter to Menoeceus* on ethics), a group of maxims, and papyrus fragments of his magnum opus, *On Nature*. Otherwise, we are almost entirely dependent on secondary citations, doxography, and the writings of his later followers.

The Epicurean physical theory is atomistic, developed out of the fifth-century system of Democritus. Per se existents are divided into bodies and space, each of them infinite in quantity. Space is, or includes, absolute void, without which motion would be impossible, while body is constituted out of physically indivisible particles, "atoms." Atoms are themselves further analyzable as sets of absolute "minima," the ultimate quanta of magnitude, posited by Epicurus to circumvent the paradoxes that Zeno of Elea had derived from the hypothesis of infinite divisibility. Atoms themselves have only the primary properties of shape, size, and weight. All secondary properties, e.g. color, are generated out of atomic compounds; given their dependent status, they cannot be added to the list of per se existents, but it does not follow, as the skeptical tradition in atomism had held, that they are not real either. Atoms are in constant rapid motion, at equal speed (since in the pure void there is nothing to slow them down). Stability emerges as an overall property of compounds, which large groups of atoms form by settling into regular patterns of complex motion, governed by the three motive principles of weight, collisions, and a minimal random movement, the "swerve," which initiates new patterns of motion and blocks the danger of determinism. Our world itself, like the countless other worlds, is such a compound, accidentally generated and of finite duration. There is no divine mind behind it, or behind the evolution of life and society: the gods are to be viewed as ideal beings, models of the Epicurean good life, and therefore blissfully detached from our affairs.

The Epicurean theory of knowledge rests on the principle that "all sensations are true." Denial of empirical cognition is argued to amount to skepticism, which is in turn rejected as a self-refuting position. Sensations are representationally (not propositionally) true. In the paradigm case of sight, thin films of atoms (Greek *eidola*, Latin *simulacra*) constantly flood off bodies, and our eyes mechanically report those that reach them, neither embroidering nor interpreting. Inference from these guaranteed (photographic, as it were) data to the nature of external objects themselves involves judgment, and there alone error can occur. Sensations thus constitute one of the three "criteria of truth," along with feelings, a criterion of values and introspective information, and *prolepseis*, or naturally acquired generic conceptions. On the basis of sense evidence, we are entitled to infer the nature of microscopic or remote phenomena. Celestial phenomena, e.g., cannot be regarded as divinely engineered (which would conflict with the *prolepsis* of the gods as tranquil), and experience supplies plenty of models that would account for them naturalistically. Such grounds amount to consistency with directly observed phenomena, and are called *ouk antimarturesis* (lack of counterevidence). Paradoxically, when several alternative explanations of the same phenomenon pass this test, all must be accepted: although only one of them can be true for each token phenomenon, the others, given their intrinsic possibility and the spatial and temporal infinity of the universe, must be true for tokens of the same type elsewhere. Fortunately, when it comes to the basic tenets of physics, it is held that only one theory passes this test of consistency with phenomena.

Epicurean ethics is hedonistic. Pleasure is our innate natural goal, to which all other values, including virtue, are subordinated. Pain is the only evil, and there is no intermediate state. Philosophy's task is to show how pleasure can be maximized, as follows: Bodily pleasure becomes more secure if we adopt a simple way of life that satisfies only our natural and necessary desires, with the support of like-minded friends. Bodily pain, when inevitable, can be outweighed by mental pleasure, which exceeds it because it can range over past, present, and future. The highest pleasure, whether of soul or body, is a satisfied state, "katastematic pleasure." The pleasures of stimulation ("kinetic pleasures"), including those resulting from luxuries, can vary this state, but have no incremental value: striving to accumulate them does not increase overall pleasure, but does increase our vulnerability to fortune. Our primary aim should instead be to minimize pain. This is achieved for the body through a simple way of life, and for the soul through the study of physics, which achieves the ultimate katastematic pleasure, "freedom from disturbance" (*ataraxia*), by eliminating the two main sources of human anguish, the fears of the gods and of death. It teaches us (a) that cosmic phenomena do not convey divine threats and (b) that death is mere disintegration of the soul, with hell an illusion. To fear our own future non-existence is as irrational as to regret the non-existence we enjoyed before we were born. Physics also teaches us how to evade determinism, which would turn moral agents into mindless fatalists: the swerve doctrine secures indeterminism, as does the logical doctrine that future-tensed propositions may be neither true nor false. The Epicureans were the first explicit defenders of free will, although we lack the details of their positive explanation of it. Finally, although Epicurean groups sought to opt out of public life, they took a keen and respectful interest in civic justice, which they analyzed not as an absolute value, but as a contract between humans to refrain from harmful activity on grounds of utility, perpetually subject to revision in the light of changing circumstances.

Epicureanism enjoyed widespread popularity, but unlike its great rival Stoicism it never entered the intellectual bloodstream of the ancient world. Its stances were dismissed by many as philistine, especially its rejection of all cultural activities not geared to the Epicurean good life. It was also increasingly viewed as atheistic, and its ascetic hedonism was misrepresented as crude sensualism (hence the modern use of 'epicure'). The school nevertheless continued to flourish down to and well beyond the end of the Hellenistic age. In the first century B.C. its exponents included Philodemus, whose fragmentarily surviving treatise *On Signs* attests to sophisticated debates on induction between Stoics and Epicureans, and Lucretius, the Roman author of the great Epicurean didactic poem *On the Nature of Things*. In the second century A.D. another Epicurean, Diogenes of Oenoanda, had his philosophical writings engraved on stone in a public colonnade, and passages have survived. Thereafter Epicureanism's prominence declined. Serious interest in it was revived by Renaissance humanists, and its atomism was an important influence on early modern physics, especially through Gassendi.

epistemic, relating to knowledge, the justification of belief, or the rational support or grounding of belief more generally. *Epistemic notions* include knowledge, knowability, ignorance, skepticism, justification, evidence, rationality, warrant, coherence, consistency, subjective probability, credence, confidence, certainty, indubitability, and fallibility. Other epistemic notions include those pointing to belief-forming methods, such as inference, perception, memory, testimony, proof, induction, and intuition.

We often contrast *epistemic considerations* with ontological ones. For instance, whether there are genuine moral properties in the world, and what makes an action morally good, are ontological considerations, while whether we can, and how we might, come to know that an action is morally good are epistemic considerations. An *epistemic theory* analyzes a notion in epistemic terms. For instance, an epistemic theory of truth might say that a proposition *p* is true if and only if *p* is knowable (in principle), or if and only if *p* would be rationally believed at the limit of inquiry.

The big *epistemic questions* in philosophy include those about the nature, sources, structure, logic, value, and limits of knowledge. They also include questions about how best to understand the notions of justification and rational support – e.g., in terms of features external to the mind (like causal and modal relations between the facts and our beliefs) versus features wholly internal to the mind (like good reasons, coherent belief-sets, or subjective probabilities that respect a suitable probability calculus).

Familiar *epistemic paradoxes* include the lottery paradox, the preface paradox, the paradox of the knower, the knowability paradox, the sleeping beauty problem, and the paradox of the surprise exam.

epistemic deontologism, a duty-based view of the nature of epistemic justification. A central concern of epistemology is to account for the distinction between justified and unjustified beliefs. According to epistemic deontologism, the concept of justification may be analyzed by using, in a specific sense relevant to the pursuit of knowledge, terms such as 'ought', 'obligatory', 'permissible', and 'forbidden'. A subject *S* is justified in believing that *p*, provided *S* does not violate any epistemic obligations – those that arise from the goal of believing what is true and not believing what is false. Equivalently, *S* is justified in believing that *p*, provided believing *p* is – from the point of view taken in the pursuit of truth – permissible for *S*. Among contemporary epistemologists, this view is held by Chisholm, BonJour, and Carl Ginet. Its significance is twofold. If justification is a function of meeting obligations, then it is, contrary to some versions of naturalistic epistemology, *normative*. Second, if the normativity of justification is deontological, the factors that determine whether a belief is justified must be internal to the subject's mind. Critics of epistemic deontologism, most conspicuously Alston, contend that belief is involuntary and thus cannot be a proper object of obligations. If, e.g., one is looking out the window and notices that it is raining, one is psychologically forced to believe that it is raining. Deontologists can reply to this objection by rejecting its underlying premise: epistemic obligations require that belief be voluntary. Alternatively, they may insist that belief is voluntary after all, and thus subject to epistemic obligations, for there is a means by which one can avoid believing what one ought not to believe: *weighing the evidence*, or *deliberation*. **See also** EPISTEMOLOGY, JUSTIFICATION. epistemic logic, the logical investigation of epistemic concepts and statements. Epistemic concepts include the concepts of knowledge, reasonable belief, justification, evidence, certainty, and related notions. Epistemic logic is usually taken to include the logic of belief, or *doxastic logic*.

Much of the recent work on epistemic logic is based on the view that it is a branch of modal logic. In the early 1950s von Wright observed that the epistemic notions *verified* (known to be true), *undecided*, and *falsified* are related to each other in the same way as the alethic modalities *necessary, contingent*, and *impossible*, and behave logically in analogous ways. This analogy is not surprising in view of the fact that the meaning of modal concepts is often explained epistemically. For example, in the 1890s Peirce defined *informational possibility* as that "which in a given (state of) information is not perfectly known not to be true," and called *informationally necessary* "that which is perfectly known to be true."

The modal logic of epistemic and doxastic concepts was studied systematically by Hintikka in his pioneering *Knowledge and Belief* (1962), which applied to the concepts of knowledge and belief the semantical method (the method of model sets) that he had used to investigate modal logic. In this approach, the truth of the proposition that a knows that p (briefly K_ap) in a possible world (or situation) u means that p holds in all epistemic alternatives of u; these are understood as worlds compatible with what a knows at u. If the relation of epistemic alternativeness is reflexive, the principle '$K_ap \rightarrow p$' (only what is the case can be known) is valid, and the assumption that the alternativeness relation is transitive validates the so-called KK-thesis, '$K_ap \rightarrow K_aK_ap$' (if a knows that p, a knows that a knows that p); these two assumptions together make the logic of knowledge similar to an S4-type modal logic. If the knowledge operator K_a and the corresponding epistemic possibility operator P_a are added to quantification theory with identity, it becomes possible to study the interplay between quantifiers and epistemic operators and the behavior of individual terms in epistemic contexts, and analyze such locutions as 'a knows who (what) b (some F) is'. The problems of epistemic logic in this area are part of the general problem of giving a coherent semantical account of propositional attitudes.

If a proposition p is true in all epistemic alternatives of a given world, so are all logical consequences of p; thus the possible-worlds semantics of epistemic concepts outlined above leads to the result that a person knows all logical consequences of what he knows. This is a paradoxical conclusion; it is called the problem of logical omniscience. The solution of this problem requires a distinction between different levels of knowledge, e.g. between tacit and explicit knowledge. A more realistic model of knowledge can be obtained by supplementing the basic possible-worlds account by an analysis of the processes by which the implicit knowledge can be activated and made explicit.

Modal epistemic logics have found fruitful applications in the recent work on knowledge representation and in the logic and semantics of questions and answers in which questions are interpreted as requests for knowledge or "epistemic imperatives."

epistemic possibility, a way the world could be, for all that is known. Epistemic possibility (sometimes called *indicative possibility*) contrasts with metaphysical possibility (sometimes called *subjunctive possibility*) – i.e., a way the world could have been, for all that is permitted by the nature of things. Generally, epistemic possibility is relativized to persons; then p is epistemically possible *for* person x just when x does not know that not-p. If I know that the coin landed heads, then for me the result *cannot* be tails (in the epistemic sense). For what I know rules that out. Nevertheless, the coin *might* (in the metaphysical sense) have landed tails. After all, tails is not ruled out by the nature of ordinary coin tosses. So metaphysical possibility does not entail epistemic possibility. Moreover, epistemic possibility does not entail metaphysical possibility. For a false mathematical claim, p, is metaphysically impossible (i.e., not true under any actual or counterfactual circumstance), even though *p* is epistemically possible for those who do not know that it is false.

Idealized notions of epistemic possibility are characterized by familiar alethic modal logics. Replacing the familiar alethic notions of necessity and possibility with the corresponding epistemic notions of knowledge and epistemic possibility, we get the following logical principles: *duality* – *p* is epistemically possible if and only if not-*p* is not known; *logical omniscience* – if *p* is a theorem, then *p* is known (hence, no logical impossibility is an epistemic possibility); *closure* – all logical consequences of what is known are also known, i.e. epistemic possibility is closed under known entailment; *factivity* – knowledge entails truth (hence, anything true is epistemically possible); *knowledge of knowledge principle* (the KK-principle) – anything known (by *x*) is known (by *x*) to be known (by *x*); *knowledge of ignorance principle* (a.k.a., socratic wisdom) – anything unknown (by *x*) is known (by *x*) to be unknown (by *x*).

epistemic principle, a principle of rationality applicable to such concepts as knowledge, justification, and reasonable belief. Epistemic principles include the principles of epistemic logic and principles that relate different epistemic concepts to one another, or epistemic concepts to non-epistemic ones (e.g., semantic concepts). Epistemic concepts include the concepts of knowledge, reasonable belief, justification, (epistemic) probability, and other concepts that are used for the purpose of assessing the reasonableness of beliefs and knowledge claims. Epistemic principles can be formulated as principles concerning *belief systems* or *information systems*, i.e. systems that characterize a person's possible *doxastic state* at a given time; a belief system may be construed as a set of (accepted) propositions or as a system of *degrees* of belief. It is possible to distinguish two kinds of epistemic principles: (a) principles concerning the rationality of a single belief system, and (b) principles concerning the rational *changes* of belief. The former include the requirements of coherence and consistency for beliefs (and for probabilities); such principles may be said to concern the *statics* of belief systems. The latter principles include various principles of belief revision and adjustment, i.e. principles concerning the *dynamics* of belief systems. **See also** CLOSURE, KK-THESIS. R.Hi.

epistemic priority. See DEPENDENCE.

epistemic privacy, the relation a person has to a proposition when only that person can have direct or non-inferential knowledge of the proposition. It is widely thought that people have epistemic privacy with respect to propositions about certain of their own mental states. According to this view, a person can know directly that he has certain thoughts or feelings or sensory experiences. Perhaps others can also know that the person has these thoughts, feelings, or experiences, but if they can it is only as a result of inference from propositions about the person's behavior or physical condition. **See also** INFERENTIAL KNOWLEDGE, PRIVILEGED ACCESS. R.Fe.

epistemic probability. See PROBABILITY.

epistemic rationality. See IRRATIONALITY.

epistemic regress argument, an argument, originating in Aristotle's *Posterior Analytics*, aiming to show that knowledge and epistemic justification have a two-tiered structure as described by epistemic foundationalism. It lends itself to the following outline regarding justification. If you have any justified belief, this belief occurs in an evidential chain including at least two links: the supporting link (i.e., the evidence) and the supported link (i.e., the justified belief). This does not mean, however, that all evidence consists of beliefs. Evidential chains might come in any of four kinds: circular chains, endless chains, chains ending in unjustified beliefs, and chains anchored in foundational beliefs that do not derive their justification from other beliefs. Only the fourth, foundationalist kind is defensible as grounding knowledge and epistemic justification.

Could all justification be inferential? A belief, *B1*, is *inferentially* justified when it owes its justification, at least in part, to some other belief, *B2*. Whence the justification for *B2?* If *B2* owes its justification to *B1*, we have a troublesome circle. How can *B2* yield justification (or evidence) for *B1* if *B2* owes its evidential status to *B1?* On the other hand, if *B2* owes its justification to another belief, *B3*, and *B3* owes its justification to yet another belief, *B4*, and so on ad infinitum, we have a troublesome endless regress of justification. Such a regress seems to deliver not actual justification, but at best merely potential justification, for the belief at its head. Actual finite humans, furthermore, seem not to be able to comprehend, or to possess, all the steps of an infinite regress of justification. Finally, if *B2* is itself unjustified, it evidently will be unable to provide justification for *B1*. It seems, then, that the structure of inferential justification does not consist of circular justification, endless regresses of justification, or unjustified starter-beliefs.

We have foundationalism, then, as the most viable account of evidential chains, so long as we understand it as the structural view that some beliefs are justified non-inferentially (i.e., without deriving justification from other beliefs), but can nonetheless provide justification for other beliefs. More precisely, if we have any justified beliefs, we have some foundational, non-inferentially justified beliefs. This regress argument needs some refinement before its full force can be appreciated. With suitable refinement, however, it can seriously challenge such alternatives to foundationalism as coherentism and contextualism. The regress argument has been a key motivation for foundationalism in the history of epistemology.

epistemic responsibilism, an account of the meaning of the concept of epistemic justification on which 'epistemically justified belief' is to be defined as 'epistemically responsible belief'. As such, the account is conceptual and not about the constitutive properties of justification: what makes beliefs justified or unjustified. Typically, the content of epistemic responsibility is articulated by invoking the truth goal: having true beliefs and avoiding false beliefs. To be epistemically responsible is to form beliefs in a way that serves the pursuit of truth; forming beliefs otherwise is epistemically irresponsible. This formula, however, does not indicate how, in pursuing truth, one should go about forming beliefs. A prominent answer is that one is epistemically responsible if one believes what one's evidence supports; irresponsible, if one believes what lacks such support.

A major objection to responsibilism is that what renders beliefs epistemically responsible might not serve truth. It might plausibly seem to me that method *M* is likely to produce true beliefs when in fact *M* is highly unreliable. Here a belief I arrive at using *M* would be responsibly held, but not *epistemically* justified since I acquired it using a non-truth-conducive method. In response, advocates of epistemic responsibilism distinguish between de facto reliability and reliability as judged from within the subject's perspective and claim that epistemic justification concerns the latter.

A second objection is that epistemically justified belief cannot be defined in terms of epistemic responsibility because (a) responsibility requires control, and (b) we do not have control over our beliefs. For example, when we see that it is raining, we cannot help believing it is raining. There are two responses. The first is that beliefs formed as a response to our epistemic reasons are no less under our control than actions formed as a response to our practical reasons. The second response is that we have *indirect* control over what we believe and this suffices for the concept of responsibility to apply to beliefs.

An alternative version of epistemic responsibility avoids both objections. Some theorists argue that, in addition to truth, wisdom and understanding are important goals. An epistemically responsible agent develops stable habits of belief formation that promote the full range of epistemic goals. On this account, to be epistemically responsible is to believe in a way that exhibits epistemic virtues such as truthfulness, curiosity, open-mindedness, and attentiveness.

epistemological particularism. See PROBLEM OF THE CRITERION.

epistemology (from Greek *episteme*, 'knowledge', and *logos*, 'explanation'), the study of the nature of knowledge and justification; specifically, the study of (a) the defining features, (b) the substantive conditions or sources, and (c) the limits of knowledge and justification. These three categories are represented by traditional philosophical controversy over the analysis of knowledge and justification, the sources of knowledge and justification (e.g., rationalism vs. empiricism), and the viability of skepticism about knowledge and justification.

Kinds of knowledge. Knowledge can be either explicit or tacit. Explicit knowledge is self-conscious in that the knower is aware of the relevant state of knowledge, whereas tacit knowledge is implicit, hidden from self-consciousness. Much of our knowledge is tacit: it is genuine but we are unaware of the relevant states of knowledge, even if we can achieve awareness upon suitable reflection. In this regard, knowledge resembles many of our psychological states. The existence of a psychological state in a person does not require the person's awareness of that state, although it may require the person's awareness of an object of that state (such as what is sensed or perceived).

Philosophers have identified various species of knowledge: for example, propositional knowledge (*that* something is so) – in psychological literature, sometimes called *declarative knowledge* – non-propositional knowledge *of* something (e.g., knowledge by acquaintance, or by direct awareness), empirical (a posteriori) propositional knowledge, non-empirical (a priori) propositional knowledge, and knowledge of how to do something – in psychological literature, sometimes called *procedural knowledge*. Philosophical controversy has arisen over distinctions between such species, for example, over (i) the relations between some of these species (e.g., does knowing-how reduce to knowledge-that?), and (ii) the viability of some of these species (e.g., is there really such a thing as, or even a coherent notion of, a priori knowledge?). A primary concern of classical modern philosophy, in the seventeenth and eighteenth centuries, was the extent of our a priori knowledge relative to the extent of our a posteriori knowledge. Such rationalists as Descartes, Leibniz, and Spinoza contended that all genuine knowledge of the real world is a priori, whereas such empiricists as Locke, Berkeley, and Hume argued that all such knowledge is a posteriori. In his *Critique of Pure Reason* (1781), Kant sought a grand reconciliation, aiming to preserve the key lessons of both rationalism and empiricism.

Since the seventeenth and eighteenth centuries, a posteriori knowledge has been widely regarded as knowledge that depends for its supporting ground on some specific sensory or perceptual experience; and a priori knowledge has been widely regarded as knowledge that does not depend for its supporting ground on such experience. Kant and others have held that the supporting ground for a priori knowledge comes solely from purely intellectual processes called "pure reason" or "pure understanding." Knowledge of logical and mathematical truths typically serves as a standard case of a priori knowledge, whereas knowledge of the existence or presence of physical objects typically serves as a standard case of a posteriori knowledge. A major task for an account of a priori knowledge is the explanation of what the relevant purely intellectual processes are, and of how they contribute to non-empirical knowledge. An analogous task for an account of a posteriori knowledge is the explanation of what sensory or perceptual experience is and how it contributes to empirical knowledge. More fundamentally, epistemologists have sought an account of propositional knowledge *in general*, i.e. an account of what is common to a priori and a posteriori knowledge. Ever since Plato's *Meno* and *Theaetetus* (c.400 B.C.), epistemologists have tried to identify the essential, defining components of knowledge. Identifying these components will yield an analysis of knowledge. A prominent traditional view, suggested by Plato and Kant among others, is that propositional knowledge (*that* something is so) has three individually necessary and jointly sufficient components: justification, truth, and belief. On this view, propositional knowledge is, by definition, justified true belief. This is the tripartite definition that has come to be called the *standard analysis*. We can clarify it by attending briefly to each of its three conditions.

The belief condition. This requires that anyone who knows that *p* (where *p* stands for any proposition or statement) must believe that *p*. If, therefore, you do not believe that minds are brains (say, because you have not considered the matter at all), then you do not know that minds are brains. A knower must be psychologically related somehow to a proposition that is an object of knowledge for that knower. Proponents of the standard analysis hold that only belief can provide the needed psychological relation. Philosophers do not share a uniform account of belief, but some considerations supply common ground. Beliefs are not actions of assenting to a proposition; they rather are dispositional psychological states that can exist even when unmanifested. (You do not cease believing that 2 + 2 = 4, e.g., whenever your attention leaves arithmetic.) Our believing that *p* seems to require that we have a *tendency* to assent to *p* in certain situations, but it seems also to be more than just such a tendency. What else believing requires remains highly controversial among philosophers.

Some philosophers have opposed the belief condition of the standard analysis on the ground that we can accept, or assent to, a known proposition without actually believing it. They contend that we can accept a proposition even if we fail to acquire a tendency, required by believing, to accept that proposition in certain situations. On this view, acceptance is a psychological act that does not entail any dispositional psychological state, and such acceptance is sufficient to relate a knower psychologically to a known proposition. However this view fares, one underlying assumption of the standard analysis seems correct: our concept of knowledge requires that a knower be psychologically related somehow to a known proposition. Barring that requirement, we shall be hard put to explain how knowers *psychologically possess* their knowledge of known propositions.

Even if knowledge requires belief, belief that *p* does not require knowledge that *p*, since belief can typically be false. This observation, familiar from Plato's *Theaetetus*, assumes that knowledge has a truth condition. On the standard analysis, if you know that *p*, then it is true that *p*. If, therefore, it is false that minds are brains, then you do not know that minds are brains. It is thus misleading to say, e.g., that astronomers before Copernicus knew that the earth is flat; at best, they justifiably believed that they knew this.

The truth condition. This condition of the standard analysis has not attracted any serious challenge. Controversy over it has focused instead on Pilate's vexing question: What is truth? This question concerns what truth *consists in*, not our ways of *finding out* what is true. Influential answers come from at least three approaches: truth as correspondence (i.e., agreement, of some specified sort, between a proposition and an actual situation); truth as coherence (i.e., interconnectedness of a proposition with a specified system of propositions); and truth as pragmatic cognitive value (i.e., usefulness of a proposition in achieving certain intellectual goals). Without assessing these prominent approaches, we should recognize, in accord with the standard analysis, that our concept of knowledge seems to have a factual requirement: we genuinely know that *p* only if *it is the case that p*. The pertinent notion of "its being the case" seems equivalent to the notion of "how reality is" or "how things really are." The latter notion seems essential to our notion of knowledge, but is open to controversy over its explication.

The justification condition. Knowledge is not simply true belief. Some true beliefs are supported only by lucky guesswork and hence do not qualify as knowledge. Knowledge requires that the satisfaction of its belief condition be "appropriately related" to the satisfaction of its truth condition. This is one broad way of understanding the justification condition of the standard analysis. More specifically, we might say that a knower must have *adequate indication* that a known proposition is true. If we understand such adequate indication as a sort of *evidence* indicating that a proposition is true, we have reached the traditional general view of the justification condition: justification as evidence. Questions about justification attract the lion's share of attention in contemporary epistemology. Controversy focuses on the meaning of 'justification' as well as on the substantive conditions for a belief's being justified in a way appropriate to knowledge.

Current debates about the meaning of 'justification' revolve around the question whether, and if so how, the concept of epistemic (knowledge-relevant) justification is normative. Since the 1950s Chisholm has defended the following deontological (obligation-oriented) notion of justification: the claim that a proposition, *p*, is epistemically justified for you *means* that it is false that you ought to refrain from accepting *p*. In other terms, to say that *p* is epistemically justified is to say that accepting *p* is *epistemically permissible* – at least in the sense that accepting *p* is consistent with a certain set of epistemic rules. This deontological construal enjoys wide representation in contemporary epistemology A normative construal of justification need not be deontological; it need not use the notions of obligation and permission. Alston, for instance, has introduced a non-deontological normative concept of justification that relies mainly on the notion of what is *epistemically good* from the viewpoint of maximizing truth and minimizing falsity. Alston links epistemic goodness to a belief's being based on adequate grounds in the absence of overriding reasons to the contrary.

Some epistemologists shun normative construals of justification as superfluous. One noteworthy view is that 'epistemic justification' means simply 'evidential support' of a certain sort. To say that *p* is epistemically justifiable to some extent for you is, on this view, just to say that *p* is supportable to some extent by your overall evidential reasons. This construal will be non-normative so long as the notions of supportability and an evidential reason are non-normative. Some philosophers have tried to explicate the latter notions without relying on talk of epistemic permissibility or epistemic goodness. We can understand the relevant notion of "support" in terms of non-normative notions of entailment and explanation (or, answering why-questions). We can understand the notion of an "evidential reason" via the notion of a psychological state that can stand in a certain truth-indicating support relation to propositions. For instance, we might regard non-doxastic states of "seeming to perceive" something (e.g., seeming to see a dictionary here) as foundational truth indicators for certain physical-object propositions (e.g., the proposition that there is a dictionary here), in virtue of those states being best explained by those propositions. If anything resembling this approach succeeds, we can get by without the aforementioned normative notions of epistemic justification.

Foundationalism versus coherentism. Talk of foundational truth indicators brings us to a key controversy over justification: Does epistemic justification, and thus knowledge, have foundations, and if so, in what sense? This question can be clarified as the issue of whether some beliefs can not only (a) have their epistemic justification *non-inferentially* (i.e., apart from evidential support from any other beliefs), but also (b) provide epistemic justification for all justified beliefs that lack such non-inferential justification. Foundationalism gives an affirmative answer to this issue, and is represented in varying ways by, e.g., Aristotle, Descartes, Russell, C. I. Lewis, and Chisholm.

Foundationalists do not share a uniform account of non-inferential justification. Some construe non-inferential justification as *self*-justification. Others reject literal self-justification for beliefs, and argue that foundational beliefs have their non-inferential justification in virtue of evidential support from the deliverances of *non-belief* psychological states, e.g. perception ("seeming-to-perceive" states), sensation ("seeming-to-sense" states), or memory ("seeming-to-remember" states). Still others understand non-inferential justification in terms of a belief's being "reliably produced" – i.e., caused and sustained by some non-belief belief-producing process or source (e.g., perception, memory, introspection) that tends to produce true rather than false beliefs. This last view takes the causal source of a belief to be crucial to its justification. Unlike Descartes, contemporary foundationalists clearly separate claims to non-inferential, foundational justification from claims to certainty. They typically settle for a *modest* foundationalism implying that foundational beliefs need not be indubitable or infallible. This contrasts with the radical foundationalism of Descartes.

The traditional competitor to foundationalism is the coherence theory of justification, i.e. epistemic coherentism. This is not the coherence definition of truth; it rather is the view that the *justification* of any belief depends on that belief's having evidential support from some other belief via coherence relations such as entailment or explanatory relations. Notable proponents include Hegel, Bosanquet, and Sellars. A prominent contemporary version of epistemic coherentism states that evidential coherence relations among beliefs are typically explanatory relations. The rough idea is that a belief is justified for you so long as it either best explains, or is best explained by, some member of the system of beliefs that has maximal explanatory power for you. Contemporary coherentism is uniformly systemic or holistic; it finds the ultimate source of justification in a *system* of interconnected beliefs or potential beliefs.

One problem has troubled all versions of coherentism that aim to explain empirical justification: the *isolation argument*. According to this argument, coherentism entails that you can be epistemically justified in accepting an empirical proposition that is incompatible with, or at least improbable given, your total empirical evidence. The key assumption of this argument is that your total empirical evidence includes *non-belief* sensory and perceptual awareness-states, such as your feeling pain or your seeming to see something. These are not belief-states. Epistemic coherentism, by definition, makes justification a function solely of coherence relations between propositions, such as propositions one believes or accepts. Thus, such coherentism seems to isolate justification from the evidential import of non-belief awareness-states. Coherentists have tried to handle this problem, but no resolution enjoys wide acceptance.

Causal and contextualist theories. Some contemporary epistemologists endorse contextualism regarding epistemic justification, a view suggested by Dewey, Wittgenstein, and Kuhn, among others. On this view, all justified beliefs depend for their evidential support on some unjustified beliefs that need no justification. In any context of inquiry, people simply assume (the acceptability of) some propositions as starting points for inquiry, and these "contextually basic" propositions, though lacking evidential support, can serve as evidential support for other propositions. Contextualists stress that contextually basic propositions can vary from context to context (e.g., from theological inquiry to biological inquiry) and from social group to social group. The main problem for contextualists comes from their view that *un*justified assumptions can provide epistemic justification for other propositions. We need a precise explanation of how an unjustified assumption can yield evidential support, how a non-probable belief can make another belief probable. Contextualists have not given a uniform explanation here.

Recently some epistemologists have recommended that we give up the traditional evidence condition for knowledge. They recommend that we construe the justification condition as a *causal* condition. Roughly, the idea is that you know that *p* if and only if (a) you believe that *p*, (b) *p* is true, and (c) your believing that *p* is causally produced and sustained by the fact that makes *p* true. This is the basis of the *causal theory of knowing*, which comes with varying details. Any such causal theory faces serious problems from our knowledge of universal propositions. Evidently, we know, for instance, that all dictionaries are produced by people, but our believing that this is so seems not to be causally supported by the fact that all dictionaries are humanly produced. It is not clear that the latter fact causally produces *any* beliefs.

Another problem is that causal theories typically neglect what seems to be crucial to any account of the justification condition: the requirement that justificational support for a belief be *accessible*, in some sense, to the believer. The rough idea is that one must be able to access, or bring to awareness, the justification underlying one's beliefs. The causal origins of a belief are, of course, often very complex and inaccessible to a believer. Causal theories thus face problems from an accessibility requirement on justification. *Internalism* regarding justification preserves an accessibility requirement on what confers justification, whereas epistemic *externalism* rejects this requirement. Debates over internalism and externalism abound in current epistemology, but internalists do not yet share a uniform detailed account of accessibility.

The Gettier problem. The standard analysis of knowledge, however elaborated, faces a devastating challenge that initially gave rise to causal theories of knowledge: the *Gettier problem*. In 1963 Edmund Gettier published a highly influential challenge to the view that if you have a justified true belief that *p*, then you know that *p*. Here is one of Gettier's counterexamples to this view: Smith is justified in believing the false proposition that (i) Jones owns a Ford. On the basis of (i), Smith infers, and thus is justified in believing, that (ii) either Jones owns a Ford or Brown is in Barcelona. As it happens, Brown is in Barcelona, and so (ii) is true. So, although Smith is justified in believing the true proposition (ii), Smith does not know (ii).

Gettier-style counterexamples are cases where a person has justified true belief that *p* but lacks knowledge that *p*. The Gettier problem is the problem of finding a modification of, or an alternative to, the standard analysis that avoids difficulties from Gettier-style counterexamples. The controversy over the Gettier problem is highly complex and still unsettled. Many epistemologists take the lesson of Gettier-style counterexamples to be that propositional knowledge requires a *fourth condition*, beyond the justification, truth, and belief conditions. No specific fourth condition has received overwhelming acceptance, but some proposals have become prominent. The so-called defeasibility condition, e.g., requires that the justification appropriate to knowledge be "undefeated" in the general sense that some appropriate subjunctive conditional concerning defeaters of justification be true of that justification. For instance, one simple defeasibility fourth condition requires of Smith's knowing that *p* that there be no true proposition, *q*, such that if *q* became justified for Smith, *p* would no longer be justified for Smith. So if Smith knows, on the basis of his visual perception, that Mary removed books from the library, then Smith's coming to believe the true proposition that Mary's identical twin removed books from the library would not undermine the justification for Smith's belief concerning Mary herself. A different approach shuns subjunctive conditionals of that sort, and contends that propositional knowledge requires justified true belief that is sustained by the collective totality of actual truths. This approach requires a detailed account of when justification is undermined and restored.

The Gettier problem is epistemologically important. One branch of epistemology seeks a precise understanding of the nature (e.g., the essential components) of propositional knowledge. Our having a precise understanding of propositional knowledge requires our having a Gettier-proof analysis of such knowledge. Epistemologists thus need a defensible solution to the Gettier problem, however complex that solution is.

Skepticism. Epistemologists debate the limits, or scope, of knowledge. The more restricted we take the limits of knowledge to be, the more skeptical we are. Two influential types of skepticism are *knowledge skepticism* and *justification skepticism*. Unrestricted knowledge skepticism implies that no one knows anything, whereas unrestricted justification skepticism implies the more extreme view that no one is even justified in believing anything. Some forms of skepticism are stronger than others. Knowledge skepticism in its strongest form implies that it is *impossible* for anyone to know anything. A weaker form would deny the actuality of our having knowledge, but leave open its possibility. Many skeptics have restricted their skepticism to a particular domain of supposed knowledge: e.g., knowledge of the external world, knowledge of other minds, knowledge of the past or the future, or knowledge of unperceived items. Such limited skepticism is more common than unrestricted skepticism in the history of epistemology.

Arguments supporting skepticism come in many forms. One of the most difficult is the *problem of the criterion*, a version of which has been stated by the sixteenth-century skeptic Montaigne: "To adjudicate [between the true and the false] among the appearances of things, we need to have a distinguishing method; to validate this method, we need to have a justifying argument; but to validate this justifying argument, we need the very method at issue. And there we are, going round on the wheel." This line of skeptical argument originated in ancient Greece, with epistemology itself. It forces us to face this question: How can we specify *what* we know without having specified *how* we know, and how can we specify *how* we know without having specified *what* we know? Is there any reasonable way out of this threatening circle? This is one of the most difficult epistemological problems, and a cogent epistemology must offer a defensible solution to it. Contemporary epistemology still lacks a widely accepted reply to this urgent problem.

equality, a potent ideal concerning the status of persons or the degree or distribution among them of some morally relevant attribute, such as income, resources, primary goods, power, welfare, opportunity, needs satisfaction, capabilities, functionings, rights, or liberties. Much debate concerns which attribute 'egalitarian' should most concern – e.g., equality before the law, treating people equally, democratic equality, priority, community, solidarity, or equality of outcomes. These debates are important, since the ideal of equality plays a prominent role in a wide range of social, political, and moral debates, and the competing views have strikingly different implications.

Corresponding to different views on these questions are many different kinds of egalitarian positions. For example: (1) *Equality as universality* is a basic principle of rationality, reflecting the view that all reasons and principles must apply universally. (2) *Equality as impartiality* reflects the view that all people must be treated impartially. (3) *Equality as comparative fairness* is fundamentally concerned with how people fare *relative to others;* it reflects the view that there is an intimate connection between objectionable inequality and comparative unfairness, contending that it is unfair, or unjust, when one person is worse off than another who is no more deserving. (4) *Equality as uniformity* reflects the view that people should be equal in all respects, and is the target of many anti-egalitarian diatribes, even though no actual egalitarian espouses it. (5) *Democratic equality* is the view that citizens should be equal before the law, and that all citizens meeting certain age, legal, and competency requirements share equal political rights and responsibilities. (6) *Equality of opportunity* reflects the view that all citizens, and perhaps all people, should have an equal opportunity to compete for educational and job opportunities, to pursue a life plan of their own choosing, and, perhaps, should compete on a level playing field in that they are not to be disadvantaged by natural or social circumstances for which they are not responsible.

We may also usefully distinguish among *instrumental* egalitarianism, where equality is valuable only insofar as it promotes some *other* valuable ideal; *non-instrumental* egalitarianism, where equality is sometimes valuable *itself; ex ante* equality, roughly, equality in people's life prospects; *ex post* equality, roughly, equality in the quality of lives people lead; *procedural equality*, which focuses on people being *treated* equally (fairly); and *substantive equality*, which focuses on equality (fairness) actually obtaining in outcomes.

Many assume we should be concerned with *one* kind of equality. This is dubious. Egalitarians are pluralists, recognizing that equality cannot plausibly be their only concern. Different kinds of equality may matter to varying degrees in different contexts. Where different egalitarian considerations conflict we must weigh their competing strengths, just as we do when competing ideals conflict. Many have assumed that the notion of equality is simple, holistic, and essentially distributive. It is arguable that a central notion of equality is extremely complex, individualistic, and essentially comparative.

Many important arguments have been advanced for, and against, different egalitarian positions, and many difficult issues concerning equality must be addressed. These include whether inequality matters more at high or low levels; whether inequality is affected by variations in population size; whether inequality matters *between* societies, species, or spatial/temporal regions as much as *within* societies, species, or spatial/temporal regions; and whether egalitarians should compare whole lives, simultaneous segments of lives (say, today's elderly with today's youth), or corresponding segments of lives (say, today's elderly with tomorrow's elderly). Such questions are all important, and their answers may significantly bear on our understanding of morality, as well as equality. But whatever the ultimate answers, equality is likely to remain a powerful ideal, exercising significant influence on a wide array of social, political, and moral issues.

equipollence, term used by Sextus Empiricus to express the view that there are arguments of equal strength on all sides of any question and that therefore we should suspend judgment on every question that can be raised. **See also** **SEXTUS EMPIRICUS.** R.P.

equipossible. See EQUIPROBABLE.

equiprobable, having the same probability. Sometimes used in the same way as 'equipossible', the term is associated with Laplace's (the "classical") interpretation of probability, where the probability of an event is the ratio of the number of equipossibilities favorable to the event to the total number of equipossibilities. For example, the probability of rolling an even number with a "fair" six-sided die is ½ – there being *three* equipossibilities (2, 4, 6) favorable to even and *six* equipossibilities (1, 2, 3, 4, 5, 6) in all (and $^3/_6$ = ½). The concept is now generally thought not to be widely applicable to the interpretation of probability, since natural equipossibilities are not always at hand (as in assessing the probability of a thermonuclear war tomorrow). **See also** **PROBABILITY.** E.Ee.

equivalence, mutual inferability. The following are main kinds: two statements are materially equivalent provided they have the same truth-value, and logically equivalent provided each can be deduced from the other; two sentences or words are equivalent in meaning provided they can be substituted for each other in any context without altering the meaning of that context. In truth-functional logic, two statements are logically equivalent if they can never have truth-values different from each other. In this sense of 'logically equivalent' all tautologies are equivalent to each other and all contradictions are equivalent to each other. Similarly, in extensional set theory, two classes are equivalent provided they have the same numbers, so that all empty classes are regarded as equivalent. In a non-extensional set theory, classes would be equivalent only if their conditions of membership were logically equivalent or equivalent in meaning. R.P.

equivalence, behavioral. See TURING MACHINE.

equivalence class. See PARTITION, RELATION.

equivalence condition. See CONFIRMATION.

equivalence relation. See PARTITION, RELATION.

equivocation, the use of an expression in two or more different senses in a single context. For example, in 'The end of anything is its perfection. But the end of life is death; so death is the perfection of life', the expression 'end' is first used in the sense of 'goal or purpose,' but in its second occurrence 'end' means 'termination'. The use of the two senses in this context is an equivocation. Where the context in which the expression used is an argument, the fallacy of equivocation may be committed. **See also** **INFORMAL FALLACY.** W.K.W.

Er, myth of. See MYTH OF ER.

Erasmus, Desiderius (1466?–1536), Dutch scholar and philosopher who played an important role in Renaissance humanism. Like his Italian forerunners Petrarch, Coluccio Salutati, Lorenzo Valla, Leonardo Bruni, and others, Erasmus stressed within philosophy and theology the function of philological precision, grammatical correctness, and rhetorical elegance. But for Erasmus the virtues of *bonae literarae* which are cultivated by the study of authors of Latin and Greek antiquity must be decisively linked with Christian spirituality. Erasmus has been called (by Huizinga) the first modern intellectual because he tried to influence and reform the mentality of society by working within the shadow of ecclesiastical and political leaders. He became one of the first humanists to make efficient use of the then new medium of printing. His writings embrace various forms, including diatribe, oration, locution, comment, dialogue, and letter.

After studying in Christian schools and living for a time in the monastery of Steyn near Gouda in the Netherlands, Erasmus worked for different patrons. He gained a post as secretary to the bishop of Kamerijk, during which time he wrote his first published book, the *Adagia* (1st ed., 1500), a collection of annotated Latin adages. Erasmus was an adviser to Emperor Charles V, to whom he dedicated his *Institutio principii Christiani* (1516). After studies at the University of Paris, where he attended lectures by the humanist Faber Stapulensis, Erasmus was put in touch by his patron, Lord Mountjoy, with the British humanists John Colet and Thomas More. Erasmus led a restless life, residing in several European cities, including London, Louvain, Basel, Freiburg, Bologna, Turin (where he was awarded a doctorate of theology in 1506), and Rome.

By using the means of modern philology, which led to the ideal of the *bonae literarae*, Erasmus tried to reform the Christian-influenced mentality of his times. Inspired by Valla's *Annotationes* to the New Testament, he completed a new Latin translation of the New Testament, edited the writings of the early church fathers, especially St. Hieronymus, and wrote several commentaries on psalms. He tried to regenerate the spirit of early Christianity by laying bare its original sense against the background of scholastic interpretation. In his view, the rituals of the existing church blocked the development of an authentic Christian spirituality. Though Erasmus shared with Luther a critical approach toward the existing church, he did not side with the Reformation. His *Diatribe de libero arbitrio* (1524), in which he pleaded for the free will of man, was answered by Luther's *De servo arbitrio*. The historically most influential books of Erasmus were *Enchirion militis Christiani* (1503), in which he attacked hirelings and soldiers; the *Encomium moriae id est Laus stultitiae* (1511), a satire on modern life and the ecclesiastical pillars of society; and the sketches of human life, the *Colloquia* (first published in 1518, often enlarged until 1553). In the small book *Querela pacis* (1517), he rejected the ideology of justified wars propounded by Augustine and Aquinas. Against the madness of war Erasmus appealed to the virtues of tolerance, friendliness, and gentleness. All these virtues were for him the essence of Christianity.

Erfahrung, German term translated, especially since Kant, as 'experience'. Kant does not use it as a technical term; rather, it indicates that which requires explanation through more precisely drawn technical distinctions such as those among 'sensibility', 'understanding', and 'reason'. In the early twentieth century, Husserl sometimes distinguishes between *Erfahrung* and *Erlebnis*, the former indicating experience as capable of being thematized and methodically described or analyzed, the latter experience as "lived through" and never fully available to analysis. Such a distinction occasionally reappears in later texts of phenomenology and existentialism. **See also** ERLEBNIS. J.P.Su.

Erigena, John Scotus, also called John the Scot, Eriugena, and Scottigena (c.810–77), Irish-born scholar and theologian who taught grammar and dialectics at the court of Charles the Bald near Laon from 845 on. In a controversy in 851, John argued that there is only one predestination, to good, since evil is strictly nothing. Thus no one is compelled to evil by God's foreknowledge, since, strictly speaking, God has no foreknowledge of what is not. But his reliance on dialectic, his Origenist conception of the world as a place of education repairing the damage done by sin, his interest in cosmology, and his perceived Pelagian tendencies excited opposition. Attacked by Prudentius of Troyes and Flores of Lyons, he was condemned at the councils of Valencia (855) and Langres (859). Charles commissioned him to translate the works of Pseudo-Dionysius and the *Ambigua* of Maximus the Confessor from the Greek. These works opened up a new world, and John followed his translations with commentaries on the Gospel of John and Pseudo-Dionysius, and then his chief work, the *Division of Nature*, or *Periphyseon* (826–66), in the Neoplatonic tradition.

He treats the universe as a procession from God, everything real in nature being a trace of God, and then a return to God through the presence of nature in human reason and man's union with God. John held that the nature of man is not destroyed by union with God, though it is deified. He was condemned for pantheism at Paris in 1210. J.Lo.

eristic, the art of controversy, often involving fallacious but persuasive reasoning. The ancient Sophists brought this art to a high level to achieve their personal goal. They may have found their material in the "encounters" in law courts as well as in daily life. To enhance persuasion they endorsed the use of unsound principles such as hasty generalizations, faulty analogies, illegitimate appeal to authority, the *post hoc ergo propter hoc* (i.e., 'after this, therefore because of this'), and other presumed principles. Aristotle exposed eristic argumentation in his *Sophistical Refutations*, which itself draws examples from Plato's *Euthydemus*. From this latter work comes the well-known example 'That dog is a father and that dog is his; therefore that dog is his father'. What is perhaps worse than its obvious invalidity is that the argument is superficially similar to a sound argument such as 'This is a table and this is brown; therefore this is a brown table'. In the *Sophistical Refutations* Aristotle undertakes to find procedures for detecting bad arguments and to propose rules for constructing sound arguments. **See also** DIALECTIC, INFORMAL FALLACY, SYLLOGISM. I.Bo.

Erklärung. See VERSTEHEN.

Erlebnis, German term for experience used in late nineteenth- and early twentieth-century German philosophy. *Erlebnis* denotes experience in all its direct immediacy and lived fullness. It contrasts with the more typical German word *Erfahrung*, denoting ordinary experience as mediated through intellectual and constructive elements. As immediate, *Erlebnis* eludes conceptualization, in both the lived present and the interiority of experience. As direct, *Erlebnis* is also disclosive and extraordinary: it reveals something real that otherwise escapes thinking. Typical examples include art, religion, and love, all of which also show the anti-rationalist and polemical uses of the concept. It is especially popular among the Romantic mystics like Novalis and the anti-rationalists Nietzsche and Bergson, as well as in phenomenology, *Lebensphilosophie*, and existentialism.

In post-Hegelian German philosophy, the term describes two aspects of subjectivity. The first concerns the epistemology of the human sciences and of phenomenology. Against naturalism and objectivism, philosophers appeal to the ineliminable, subjective qualities of experience to argue that interpreters must understand "what it is like to be" some experiencing subject, from the inside. The second use of the term is to denote extraordinary and interior experiences like art, religion, freedom, and vital energy. In both cases, it is unclear how such experience could be identified or known in its immediacy, and much recent German thought, such as Heidegger and hermeneutics, rejects the concept.

See also ERFAHRUNG, EXISTENTIALISM, PHENOMENOLOGY. J.Bo.

Eros, the Greek god of erotic love. Eros came to symbolize various aspects of love, first appearing in Hesiod in opposition to reason. In general, however, Eros was seen by Greeks (e.g., Parmenides) as a unifying force. In Empedocles, it is one of two external forces explaining the history of the cosmos, the other being Strife. These forces resemble the "hidden harmony" of Heraclitus.

The *Symposium* of Plato is the best-known ancient discussion of Eros, containing speeches from various standpoints – mythical, sophistic, etc. Socrates says he has learned from the priestess Diotima of a nobler form of Eros in which sexual desire can be developed into the pursuit of understanding the Form of beauty. The contrast between agape and Eros is found first in Democritus. This became important in Christian accounts of love. In Neoplatonism, Eros represented the mystical union with Being sought by philosophers. Eros has become important recently in the work of Continental writers.

erotetic, in the strict sense, pertaining to questions. Erotetic logic is the logic of questions. Different conceptions of questions yield different erotetic logics. A Platonistic approach holds that questions exist independently of interrogatives. For P. Tichý, a question is a function on possible worlds, the right answer being the value of the function at the actual world. Erotetic logic is the logic of such functions. In the epistemic-imperative approach (of L. Åqvist, Hintikka, et al.), one begins with a system for epistemic sentences and embeds this in a system for imperative sentences, thus obtaining sentences of the form 'Make it the case that I know . . .' and complex compounds of such sentences. Certain ones of these are defined to be interrogatives. Then erotetic logic is the logic of epistemic imperatives and the conditions for satisfaction of these imperatives. In the abstract interrogative approach (of N. Belnap, T. Kubiriski, and many others), one chooses certain types of expression to serve as interrogatives and, for each type, specifies what expressions count as answers of various kinds (direct, partial, . . .). On this approach we may say that interrogatives express questions, or we may identify questions with interrogatives, in which case the only meaning that an interrogative has is that it has the answers that it does. Either way, the emphasis is on interrogatives, and erotetic logic is the logic of systems that provide interrogatives and specify answers to them. In the broad sense, 'erotetic' designates what pertains to utterance-and-response. In this sense erotetic logic is the logic of the relations between (1) sentences of many kinds and (2) the expressions that count as appropriate replies to them. This includes not only the relations between question and answer but also, e.g., between assertion and agreement or denial, command and report of compliance or refusal, and (for many types of sentence *S*) between *S* and various corrective replies to *S* (e.g., denial of the presupposition of *S*). Erotetic logics may differ in the class of sentences treated, the types of response counted as appropriate, the assignment of other content (presupposition, projection, etc.), and other details. **See also** DEONTIC LOGIC, EPISTEMIC LOGIC, MODAL LOGIC. essence. See ESSENTIALISM.

essence, nominal. See ESSENTIALISM.

essence, real. See ESSENTIALISM.

essentialism, a metaphysical theory that objects have essences and that there is a distinction between essential and non-essential or accidental predications. Different issues have, however, been central in debates about essences and essential predication in different periods in the history of philosophy. At present, it is commitment to the notion of *de re* modality that is generally taken to render a theory essentialist; but in the essentialist tradition stemming from Aristotle, discussions of essence and essential predication focus on the distinction between *what* an object is and *how* it is. According to Aristotle, the universals that an ordinary object instantiates include some that mark it out as what it is and others that characterize it in some way but do not figure in an account of what it is. In the *Categories*, he tells us that while the former are *said of* the object, the latter are merely *present in* it; and in other writings, he distinguishes between what he calls *kath hauto*, or per se, predications (where these include the predication of what-universals) and *kata sumbebekos*, or *per accidens*, predications (where these include the predication of how-universals). He concedes that universals predicated of an object *kath hauto* are necessary to that object; but he construes the necessity here as derivative. It is because a universal marks out an entity, *x*, as what *x* is and hence underlies its being the thing that it is that the universal is necessarily predicated of *x*.

The concept of definition is critically involved in Aristotle's essentialism. First, it is the kind – *infima species* – under which an object falls or one of the items (genus or differentia) included in the definition of that kind that is predicated of the object *kath hauto*. But, second, Aristotle's notion of an essence just is the notion of the ontological correlate of a definition. The term in his writings we translate as 'essence' is the expression *to ti ein einai* (the what it is to be). Typically, the expression is followed by a substantival expression in the dative case, so that the expressions denoting essences are phrases like 'the what it is to be for a horse' and 'the what it is to be for an oak tree'; and Aristotle tells us that, for any kind, *K*, the what it is to be for a *K* just is that which we identify when we provide a complete and accurate definition of *K*.

Now, Aristotle holds that there is definition only of universals; and this commits him to the view that there are no individual essences. Although he concedes that we can provide definitions of universals from any of his list of ten categories, he gives pride of place to the essences of universals from the category of substance. Substance-universals can be identified without reference to essences from other categories, but the essences of qualities, quantities, and other non-substances can be defined only by reference to the essences of substances. In his early writings, Aristotle took the familiar particulars of common sense (things like the individual man and horse of *Categories* V) to be the primary substances; and in these writings it is the essences we isolate by defining the kinds or species under which familiar particulars fall that are construed as the basic or paradigmatic essences. However, in later writings, where ordinary particulars are taken to be complexes of matter and form, it is the substantial forms of familiar particulars that are the primary substances, so their essences are the primary or basic essences; and a central theme in Aristotle's most mature writings is the idea that the primary substances and their essences are necessarily one and the same in number.

The conception of essence as the ontological correlate of a definition – often called *quiddity* – persists throughout the medieval tradition; and in early modern philosophy, the idea that the identity of an object is constituted by what it is plays an important role in Continental rationalist thinkers. Indeed, in the writings of Leibniz, we find the most extreme version of traditional essentialism. Whereas Aristotle had held that essences are invariably general, Leibniz insisted that each individual has an essence peculiar to it. He called the essence associated with an entity its *complete individual concept* and maintained that the individual concept somehow entails all the properties exemplified by the entity. Accordingly, Leibniz believed that an omniscient being could, for each possible world and each possible individual, infer from the individual concept of that individual the whole range of properties exemplified by that individual in that possible world. But, then, from the perspective of an omniscient being, all of the propositions identifying the properties the individual actually exhibits would express what Aristotle called *kath hauto* predications. Leibniz, of course, denied that our perspective is that of an omniscient being; we fail to grasp individual essences in their fullness, so from our perspective, the distinction between essential and accidental predications holds.

While classical rationalists espoused a thoroughgoing essentialism, the Aristotelian conceptions of essence and definition were the repeated targets of attacks by classical British empiricists. Hobbes, e.g., found the notion of essence philosophically useless and insisted that definition merely displays the meanings conventionally associated with linguistic expressions. Locke, on the other hand, continued to speak of essences; but he distinguished between real and nominal essences. As he saw it, the familiar objects of common sense are collections of co-present sensible ideas to which we attach a single name like 'man' or 'horse'. Identifying the ideas constitutive of the relevant collection gives us the nominal essence of a man or a horse. Locke did not deny that real essences might underlie such collections, but he insisted that it is nominal rather than real essences to which we have epistemic access. Hume, in turn, endorsed the idea that familiar objects are collections of sensible ideas, but rejected the idea of some underlying real essence to which we have no access; and he implicitly reinforced the Hobbesian critique of Aristotelian essences with his attack on the idea of *de re* necessities. So definition merely expresses the meanings we conventionally associate with words, and the only necessity associated with definition is linguistic or verbal necessity.

From its origins, the twentieth-century analytic tradition endorsed the classical empiricist critique of essences and the Humean view that necessity is merely linguistic. Indeed, even the Humean concession that there is a special class of statements true in virtue of their meanings came into question in the 1940s and 1950s, when philosophers like Quine argued that it is impossible to provide a non-circular criterion for distinguishing analytic and synthetic statements. So by the late 1950s, it had become the conventional wisdom of philosophers in the Anglo-American tradition that both the notion of a real essence and the derivative idea that some among the properties true of an object are essential to that object are philosophical dead ends. But over the past few decades, developments in the semantics of modal logic have called into question traditional empiricist skepticism about essence and modality and have given rise to a rebirth of essentialism. In the late 1950s and early 1960s, logicians (e.g., Kripke, Hintikka, and Richard Montague) showed how formal techniques that have as their intuitive core the Leibnizian idea that necessity is truth in all possible worlds enable us to provide completeness proofs for a whole range of nonequivalent modal logics. Metaphysicians seized on the intuitions underlying these formal methods. They proposed that we take the picture of alternative possible worlds seriously and claimed that attributions of *de dicto* modality (necessity and possibility as they apply to propositions) can be understood to involve quantification over possible worlds. Thus, to say that a proposition, p, is necessary is to say that for every possible world, W, p is true in W; and to say that p is possible is to say that there is at least one possible world, W, such that p is true in W.

These metaphysicians went on to claim that the framework of possible worlds enables us to make sense of *de re* modality. Whereas *de dicto* modality attaches to propositions taken as a whole, an ascription of *de re* modality identifies the modal status of an object's exemplification of an attribute. Thus, we speak of Socrates as being necessarily or essentially rational, but only contingently snub-nosed. Intuitively, the essential properties of an object are those it could not have lacked, whereas its contingent properties are properties it exemplifies but could have failed to exemplify. The "friends of possible worlds" insisted that we can make perfectly good sense of this intuitive distinction if we say that an object, *x*, exhibits a property, *P*, essentially just in case *x* exhibits *P* in the actual world and in every possible world in which *x* exists and that *x* exhibits *P* merely contingently just in case *x* exhibits *P* in the actual world, but there is at least one possible world, *W*, such that *x* exists in *W* and fails to exhibit *P* in *W*.

Not only have these neo-essentialists invoked the Leibnizian conception of alternative possible worlds in characterizing the *de re* modalities, many have endorsed Leibniz's idea that each object has an individual essence, or what is sometimes called a *haecceity*. As we have seen, the intuitive idea of an individual essence is the idea of a property an object exhibits essentially and that no other object could possibly exhibit; and contemporary essentialists have fleshed out this intuitive notion by saying that a property, *P*, is the haecceity or individual essence of an object, *x*, just in case (1) *x* exhibits *P* in the actual world and in all worlds in which *x* exists and (2) there is no possible world where an object distinct from *x* exhibits *P*. And some defenders of individual essences (like Plantinga) have followed Leibniz in holding that the haecceity of an object provides a complete concept of that object, a property such that it entails, for every possible world, *W*, and every property, *P*, either the proposition that the object in question has *P* in *W* or the proposition that it fails to have *P* in *W*. Accordingly, they agree that an omniscient being could infer from the individual essence of an object a complete account of the history of that object in each possible world in which it exists.

establishment, an official, usually statutory role filled by a religion or religious institution in a nation-state or governmental structure. The term is commonly used in reference to the doctrine affirmed in the First Amendment of the U.S. Constitution prohibiting Congress's making laws "respecting the establishment of religion." On the basis of the Due Process Clause of the Fourteenth Amendment (1868), modern jurisprudence interprets the prohibition broadly as forbidding any arm of government – federal, state, or local – to establish religion. The philosophical question here is what it is to "establish religion." The Establishment Clause prohibits government's endorsing a particular church, but questions remain concerning government acts that distribute financial support to religious institutions, including church-based charities, public services, and educational institutions.

Hence we may distinguish 'establishment' as government's endorsing a particular religion (thereby breaching the separation of church and state) from 'establishment' as government's aiding, or expressing a preference for, some particular religious institution. Both are forbidden, but the latter raises questions. A case widely considered clear is raised in *Bradfield v. Roberts* (1899), which permitted state financial support for religiously affiliated hospitals; in doing so, the state was supporting the public-service institution rather than the affiliate church. *Everson v. Board of Education* (1947) raises more problems; there the Supreme Court upheld a New Jersey policy of publicly funding the transportation of children to both public and parochial schools. The majority in *Everson* held that because the support was available to all, there was no establishment. However, in the landmark 1971 *Lemon v. Kurtzman* case, the Court struck down programs in which the state reimburses parochial schools for teaching secular subjects. The ruling specifies the non-establishment doctrine now known as the *Lemon Test*: government action must (1) have a secular legislative purpose; (2) have a primary effect that neither advances nor inhibits religion; and (3) not encourage an "excessive entanglement" between government and religion. Contemporary concerns with establishment have involved mandatory prayer in public schools and displays of religious symbols on publicly held property.

eternal recurrence. See ETERNAL RETURN.

eternal return, the doctrine that the same events, occurring in the same sequence and involving the same things, have occurred infinitely many times in the past and will occur infinitely many times in the future. Attributed most notably to the Stoics and Nietzsche, the doctrine is antithetical to philosophical and religious viewpoints that claim that the world order is unique, contingent in part, and directed toward some goal. The Stoics interpret eternal return as the consequence of perpetual divine activity imposing exceptionless causal principles on the world in a supremely rational, providential way. The world, being the best possible, can only be repeated endlessly. The Stoics do not explain why the best world cannot be everlasting, making repetition unnecessary. It is not clear whether Nietzsche asserted eternal return as a cosmological doctrine or only as a thought experiment designed to confront one with the authenticity of one's life: would one affirm that life even if one were consigned to live it over again without end? On either interpretation, Nietzsche's version, like the Stoic version, stresses the inexorability and necessary interconnectedness of all things and events, although unlike the Stoic version, it rejects divine providence. **See also NIETZSCHE, STOICISM.** W.E.M.

ethical absolutism. See RELATIVISM.

ethical constructivism, a form of anti-realism about ethics which holds that there are moral facts and truths, but insists that these facts and truths are in some way constituted by or dependent on our moral beliefs, reactions, or attitudes. For instance, an ideal observer theory that represents the moral rightness and wrongness of an act in terms of the moral approval and disapproval that an appraiser would have under suitably idealized conditions can be understood as a form of ethical constructivism. Another form of constructivism identifies the truth of a moral belief with its being part of the appropriate system of beliefs, e.g. of a system of moral and non-moral beliefs that is internally coherent. Such a view would maintain a coherence theory of moral truth. Moral relativism is a constructivist view that allows for a plurality of moral facts and truths. Thus, if the idealizing conditions appealed to in an ideal observer theory allow that different appraisers can have different reactions to the same actions under ideal conditions, then that ideal observer theory will be a version of moral relativism as well as of ethical constructivism. Or, if different systems of moral beliefs satisfy the appropriate epistemic conditions (e.g. are equally coherent), then the truth or falsity of particular moral beliefs will have to be relativized to different moral systems or codes. **See also ETHICAL OBJECTIVISM, ETHICS, IDEAL OBSERVER, KORSGAARD, RELATIVISM.** D.O.B.

ethical objectivism, the view that the objects of the most basic concepts of ethics (which may be supposed to be values, obligations, duties, oughts, rights, or whatnot) exist, or that facts about them hold, objectively and that similarly worded ethical statements by different persons make the same factual claims (and thus do not concern merely the speaker's feelings). To say that a fact is objective, or that something has objective existence, is usually to say that its holding or existence is not derivative from its being thought to hold or exist. (In the Scholastic terminology still current in the seventeenth century 'objective' had the more or less contrary meaning of having status only as an object of thought.) In contrast, fact, or a thing's existence, is subjective if it holds or exists only in the sense that it is thought to hold or exist, or that it is merely a convenient human posit for practical purposes. A fact holds, or an object exists, *intersubjectively* if somehow its acknowledgment is binding on all thinking subjects (or all subjects in some specified group), although it does not hold or exist independently of their thinking about it. Some thinkers suppose that intersubjectivity is all that can ever properly be meant by objectivity.

Objectivism may be naturalist or non-naturalist. The naturalist objectivist believes that values, duties, or whatever are natural phenomena detectable by introspection, perception, or scientific inference. Thus values may be identified with certain empirical qualities of (anybody's) experience, or duties with empirical facts about the effects of action, e.g. as promoting or hindering social cohesion. The non-naturalist objectivist (eschewing what Moore called the *naturalistic fallacy*) believes that values or obligations (or whatever items he thinks most basic in ethics) exist independently of any belief about them, but that their existence is not a matter of any ordinary fact detectable in the above ways but can be revealed to ethical intuition as standing in a necessary (but not analytic) relation to natural phenomena.

'Ethical subjectivism' usually means the doctrine that ethical statements are simply reports on the speaker's feelings (though, confusingly enough, such statements may be objectively true or false). Perhaps it ought to mean the doctrine that nothing is good or bad but thinking makes it so. Attitude theories of morality, for which such statements express, rather than report upon, the speaker's feelings, are also, despite the objections of their proponents, sometimes called subjectivist.

In a more popular usage an objective matter of fact is one on which all reasonable persons can be expected to agree, while a matter is subjective if various alternative opinions can be accepted as reasonable. What is subjective in this sense may be quite objective in the more philosophical sense in question above.

ethics, the philosophical study of morality. The word is also commonly used interchangeably with 'morality' to mean the subject matter of this study; and sometimes it is used more narrowly to mean the moral principles of a particular tradition, group, or individual. Christian ethics and Albert Schweitzer's ethics are examples. This article uses the word exclusively to mean the philosophical study. Ethics, along with logic, metaphysics, and epistemology, is one of the main branches of philosophy. It corresponds, in the traditional division of the field into formal, natural, and moral philosophy, to the last of these disciplines. It can in turn be divided into the general study of goodness, the general study of right action, applied ethics, metaethics, moral psychology, and the metaphysics of moral responsibility. These divisions are not sharp, and many important studies in ethics, particularly those that examine or develop whole systems of ethics, are interdivisional. Nonetheless, they facilitate the identification of different problems, movements, and schools within the discipline.

The first two, the general study of goodness and the general study of right action, constitute the main business of ethics. Correlatively, its principal substantive questions are what ends we ought, as fully rational human beings, to choose and pursue and what moral principles should govern our choices and pursuits. How these questions are related is the discipline's principal structural question, and structural differences among systems of ethics reflect different answers to this question. In contemporary ethics, the study of structure has come increasingly to the fore, especially as a preliminary to the general study of right action. In the natural order of exposition, however, the substantive questions come first.

Goodness and the question of ends. Philosophers have typically treated the question of the ends we ought to pursue in one of two ways: either as a question about the components of a good life or as a question about what sorts of things are good in themselves. On the first way of treating the question, it is assumed that we naturally seek a good life; hence, determining its components amounts to determining, relative to our desire for such a life, what ends we ought to pursue. On the second way, no such assumption about human nature is made; rather it is assumed that whatever is good in itself is worth choosing or pursuing. The first way of treating the question leads directly to the theory of human well-being. The second way leads directly to the theory of intrinsic value.

The first theory originated in ancient ethics, and *eudaimonia* was the Greek word for its subject, a word usually translated as 'happiness,' but sometimes translated as 'flourishing' in order to make the question of human well-being seem more a matter of how well a person is doing than how good he is feeling. These alternatives reflect the different conceptions of human well-being that inform the two major views within the theory: the view that feeling good or pleasure is the essence of human well-being and the view that doing well or excelling at things worth doing is its essence. The first view is hedonism in its classical form. Its most famous exponent among the ancients was Epicurus. The second view is perfectionism, a view that is common to several schools of ancient ethics. Its adherents include Plato, Aristotle, and the Stoics. Among the moderns, the best-known defenders of classical hedonism and perfectionism are respectively J. S. Mill and Nietzsche.

Although these two views differ on the question of what human well-being essentially consists in, neither thereby denies that the other's answer has a place in a good human life. Indeed, mature statements of each typically assign the other's answer an ancillary place. Thus, hedonism, as expounded by Epicurus, takes excelling at things worth doing – exercising one's intellectual powers and moral virtues in exemplary and fruitful ways, e.g. – as the tried and true means of experiencing life's most satisfying pleasures. And perfectionism, as developed in Aristotle's ethics, underscores the importance of pleasure – the deep satisfaction that comes from doing an important job well, e.g. as a natural concomitant of achieving excellence in things that matter. The two views, as expressed in these mature statements, differ not so much in the kinds of activities they take to be central to a good life as in the ways they explain the goodness of such a life. The chief difference between them, then, is philosophical rather than prescriptive.

The second theory, the theory of intrinsic value, also has roots in ancient ethics, specifically Plato's theory of Forms. But unlike Plato's theory, the basic tenets of which include certain doctrines about the reality and transcendence of value, the theory of intrinsic value neither contains nor presupposes any metaphysical theses. At issue in the theory is what things are good in themselves, and one can take a position on this issue without committing oneself to any thesis about the reality or unreality of goodness or about its transcendence or immanence. A list of the different things philosophers have considered good in themselves would include life, happiness, pleasure, knowledge, virtue, friendship, beauty, and harmony. The list could easily be extended.

An interest in what constitutes the goodness of the various items on the list has brought philosophers to focus primarily on the question of whether something unites them. The opposing views on this question are monism and pluralism. Monists affirm the list's unity; pluralists deny it. Plato, for instance, was a monist. He held that the goodness of everything good in itself consisted in harmony and therefore each such thing owed its goodness to its being harmonious. Alternatively, some philosophers have proposed pleasure as the sole constituent of goodness. Indeed, conceiving of pleasure as a particular kind of experience or state of consciousness, they have proposed this kind of experience as the only thing good in itself and characterized all other good things as instrumentally good, as owing their goodness to their being sources of pleasure. Thus, hedonism too can be a species of monism. In this case, though, one must distinguish between the view that it is one's own experiences of pleasure that are intrinsically good and the view that anyone's experiences of pleasure, indeed any sentient being's experiences of pleasure, are intrinsically good. The former is called (by Sidgwick) egoistic hedonism, the latter universal hedonism. This distinction can be made general, as a distinction between egoistic and universal views of what is good in itself or, as philosophers now commonly say, between agent-relative and agent-neutral value. As such, it indicates a significant point of disagreement in the theory of intrinsic value, a disagreement in which the seeming arbitrariness and blindness of egoism make it harder to defend. In drawing this conclusion, however, one must be careful not to mistake these egoistic views for views in the theory of human well-being, for each set of views represents a set of alternative answers to a different question. One must be careful, in other words, not to infer from the greater defensibility of universalism vis-à-vis egoism that universalism is the predominant view in the general study of goodness.

Right action. The general study of right action concerns the principles of right and wrong that govern our choices and pursuits. In modern ethics these principles are typically given a jural conception. Accordingly, they are understood to constitute a moral code that defines the duties of men and women who live together in fellowship. This conception of moral principles is chiefly due to the influence of Christianity in the West, though some of its elements were already present in Stoic ethics. Its ascendancy in the general study of right action puts the theory of duty at the center of that study.

The theory has two parts: the systematic exposition of the moral code that defines our duties; and its justification. The first part, when fully developed, presents complete formulations of the fundamental principles of right and wrong and shows how they yield all moral duties. The standard model is an axiomatic system in mathematics, though some philosophers have proposed a technical system of an applied science, such as medicine or strategy, as an alternative. The second part, if successful, establishes the authority of the principles and so validates the code. Various methods and criteria of justification are commonly used; no single one is canonical. Success in establishing the principles' authority depends on the soundness of the argument that proceeds from whatever method or criterion is used. One traditional criterion is implicit in the idea of an axiomatic system. On this criterion, the fundamental principles of right and wrong are authoritative in virtue of being self-evident truths. That is, they are regarded as comparable to axioms not only in being the first principles of a deductive system but also in being principles whose truth can be seen upon reflection. Use of this criterion to establish the principles' authority is the hallmark of *intuitionism*. Once one of the dominant views in ethics, its position in the discipline has now been seriously eroded by a strong, twentieth-century tide of skepticism about all claims of self-evidence.

Currently, the most influential method of justification consistent with using the model of an axiomatic system to expound the morality of right and wrong draws on the jural conception of its principles. On this method, the principles are interpreted as expressions of a legislative will, and accordingly their authority derives from the sovereignty of the person or collective whose will they are taken to express. The oldest example of the method's use is the *divine command theory*. On this theory, moral principles are taken to be laws issued by God to humanity, and their authority thus derives from God's supremacy. The theory is the original Christian source of the principles' jural conception. The rise of secular thought since the Enlightenment has, however, limited its appeal. Later examples, which continue to attract broad interest and discussion, are formalism and contractarianism.

Formalism is best exemplified in Kant's ethics. It takes a moral principle to be a precept that satisfies the formal criteria of a universal law, and it takes formal criteria to be the marks of pure reason. Consequently, moral principles are laws that issue from reason. As Kant puts it, they are laws that we, as rational beings, give to ourselves and that regulate our conduct insofar as we engage each other's rational nature. They are laws for a republic of reason or, as Kant says, a kingdom of ends whose legislature comprises all rational beings. Through this ideal, Kant makes intelligible and forceful the otherwise obscure notion that moral principles derive their authority from the sovereignty of reason.

Contractarianism also draws inspiration from Kant's ethics as well as from the social contract theories of Locke and Rousseau. Its fullest and most influential statement appears in the work of Rawls. On this view, moral principles represent the ideal terms of social cooperation for people who live together in fellowship and regard each other as equals. Specifically, they are taken to be the conditions of an ideal agreement among such people, an agreement that they would adopt if they met as an assembly of equals to decide collectively on the social arrangements governing their relations and reached their decision as a result of open debate and rational deliberation. The authority of moral principles derives, then, from the fairness of the procedures by which the terms of social cooperation would be arrived at in this hypothetical constitutional convention and the assumption that any rational individual who wanted to live peaceably with others and who imagined himself a party to this convention would, in view of the fairness of its procedures, assent to its results. It derives, that is, from the hypothetical consent of the governed.

Philosophers who think of a moral code on the model of a technical system of an applied science use an entirely different method of justification. In their view, just as the principles of medicine represent knowledge about how best to promote health, so the principles of right and wrong represent knowledge about how best to promote the ends of morality. These philosophers, then, have a teleological conception of the code. Our fundamental duty is to promote certain ends, and the principles of right and wrong organize and direct our efforts in this regard. What justifies the principles, on this view, is that the ends they serve are the right ones to promote and the actions they prescribe are the best ways to promote them. The principles are authoritative, in other words, in virtue of the wisdom of their prescriptions.

Different teleological views in the theory of duty correspond to different answers to the question of what the right ends to promote are. The most common answer is happiness; and the main division among the corresponding views mirrors the distinction in the theory of intrinsic value between egoism and universalism. Thus, egoism and universalism in the theory of duty hold, respectively, that the fundamental duty of morality is to promote, as best as one can, one's own happiness and that it is to promote, as best as one can, the happiness of humanity. The former is ethical egoism and is based on the ideal of rational self-love. The latter is *utilitarianism* and is based on the ideal of rational benevolence. Ethical egoism's most famous exponents in modern philosophy are Hobbes and Spinoza. It has had few distinguished defenders since their time. Bentham and J. S. Mill head the list of distinguished defenders of utilitarianism. The view continues to be enormously influential.

On these teleological views, answers to questions about the ends we ought to pursue determine the principles of right and wrong. Put differently, the general study of right action, on these views, is subordinate to the general study of goodness. This is one of the two leading answers to the structural question about how the two studies are related. The other is that the general study of right action is to some extent independent of the general study of goodness. On views that represent this answer, some principles of right and wrong, notably principles of justice and honesty, prescribe actions even though more evil than good would result from doing them. These views are deontological. *Fiat justitia ruat coelum* captures their spirit. The opposition between teleology and deontology in ethics underlies many of the disputes in the general study of right action.

The principal substantive and structural questions of ethics arise not only with respect to the conduct of human life generally but also with respect to specific walks of life such as medicine, law, journalism, engineering, and business. The examination of these questions in relation to the common practices and traditional codes of such professions and occupations has resulted in the special studies of *applied ethics*. In these studies, ideas and theories from the general studies of goodness and right action are applied to particular circumstances and problems of some profession or occupation, and standard philosophical techniques are used to define, clarify, and organize the ethical issues found in its domain. In medicine, in particular, where rapid advances in technology create, overnight, novel ethical problems on matters of life and death, the study of biomedical ethics has generated substantial interest among practitioners and scholars alike.

Metaethics. To a large extent, the general studies of goodness and right action and the special studies of applied ethics consist in systematizing, deepening, and revising our beliefs about how we ought to conduct our lives. At the same time, it is characteristic of philosophers, when reflecting on such systems of belief, to examine the nature and grounds of these beliefs. These questions, when asked about ethical beliefs, define the field of *metaethics*. The relation of this field to the other studies is commonly represented by taking the other studies to constitute the field of ethics proper and then taking metaethics to be the study of the concepts, methods of justification, and ontological assumptions of the field of ethics proper.

Accordingly, metaethics can proceed from an interest either in the epistemology of ethics or in its metaphysics. On the first approach, the study focuses on questions about the character of ethical knowledge. Typically, it concentrates on the simplest ethical beliefs, such as 'Stealing is wrong' and 'It is better to give than to receive', and proceeds by analyzing the concepts in virtue of which these beliefs are ethical and examining their logical basis. On the second approach, the study focuses on questions about the existence and character of ethical properties. Typically, it concentrates on the most general ethical predicates such as goodness and wrongfulness and considers whether there truly are ethical properties represented by these predicates and, if so, whether and how they are interwoven into the natural world. The two approaches are complementary. Neither dominates the other.

The epistemological approach is comparative. It looks to the most successful branches of knowledge, the natural sciences and pure mathematics, for paradigms. The former supplies the paradigm of knowledge that is based on observation of natural phenomena; the latter supplies the paradigm of knowledge that seemingly results from the sheer exercise of reason. Under the influence of these paradigms, three distinct views have emerged: naturalism, rationalism, and noncognitivism.

Naturalism takes ethical knowledge to be empirical and accordingly models it on the paradigm of the natural sciences. Ethical concepts, on this view, concern natural phenomena. Rationalism takes ethical knowledge to be a priori and accordingly models it on the paradigm of pure mathematics. Ethical concepts, on this view, concern morality understood as something completely distinct from, though applicable to, natural phenomena, something whose content and structure can be apprehended by reason independently of sensory inputs. Noncognitivism, in opposition to these other views, denies that ethics is a genuine branch of knowledge or takes it to be a branch of knowledge only in a qualified sense. In either case, it denies that ethics is properly modeled on science or mathematics. On the most extreme form of noncognitivism, there are no genuine ethical concepts; words like ‘right’, ‘wrong’, ‘good’, and ‘evil’ have no cognitive meaning but rather serve to vent feelings and emotions, to express decisions and commitments, or to influence attitudes and dispositions. On less extreme forms, these words are taken to have some cognitive meaning, but conveying that meaning is held to be decidedly secondary to the purposes of venting feelings, expressing decisions, or influencing attitudes. Naturalism is well represented in the work of Mill; rationalism in the works of Kant and the intuitionists. And noncognitivism, which did not emerge as a distinctive view until the twentieth century, is most powerfully expounded in the works of C. L. Stevenson and Hare. Its central tenets, however, were anticipated by Hume, whose skeptical attacks on rationalism set the agenda for subsequent work in metaethics.

The metaphysical approach is centered on the question of objectivity, the question of whether ethical predicates represent real properties of an external world or merely apparent or invented properties, properties that owe their existence to the perception, feeling, or thought of those who ascribe them. Two views dominate this approach. The first, *moral realism*, affirms the real existence of ethical properties. It takes them to inhere in the external world and thus to exist independently of their being perceived. For moral realism, ethics is an objective discipline, a discipline that promises discovery and confirmation of objective truths. At the same time, moral realists differ fundamentally on the question of the character of ethical properties. Some, such as Plato and Moore, regard them as purely intellective and thus irreducibly distinct from empirical properties. Others, such as Aristotle and Mill, regard them as empirical and either reducible to or at least supervenient on other empirical properties. The second view, *moral subjectivism*, denies the real existence of ethical properties. On this view, to predicate, say, goodness of a person is to impose some feeling, impulse, or other state of mind onto the world, much as one projects an emotion onto one’s circumstances when one describes them as delightful or sad. On the assumption of moral subjectivism, ethics is not a source of objective truth. In ancient philosophy, moral subjectivism was advanced by some of the Sophists, notably Protagoras. In modern philosophy, Hume expounded it in the eighteenth century and Sartre in the twentieth century.

Regardless of approach, one (and perhaps the central) problem of metaethics is how value is related to fact. On the epistemological approach, this problem is commonly posed as the question of whether judgments of value are derivable from statements of fact. Or, to be more exact, can there be a logically valid argument whose conclusion is a judgment of value and all of whose premises are statements of fact? On the metaphysical approach, the problem is commonly posed as the question of whether moral predicates represent properties that are explicable as complexes of empirical properties. At issue, in either case, is whether ethics is an autonomous discipline, whether the study of moral values and principles is to some degree independent of the study of observable properties and events. A negative answer to these questions affirms the autonomy of ethics; a positive answer denies ethics’ autonomy and implies that it is a branch of the natural sciences.

Moral psychology. Even those who affirm the autonomy of ethics recognize that some facts, particularly facts of human psychology, bear on the general studies of goodness and right action. No one maintains that these studies float free of all conception of human appetite and passion or that they presuppose no account of the human capacity for voluntary action. It is generally recognized that an adequate understanding of desire, emotion, deliberation, choice, volition, character, and personality is indispensable to the theoretical treatment of human well-being, intrinsic value, and duty. Investigations into the nature of these psychological phenomena are therefore an essential, though auxiliary, part of ethics. They constitute the adjunct field of *moral psychology*.

One area of particular interest within this field is the study of those capacities by virtue of which men and women qualify as moral agents, beings who are responsible for their actions. This study is especially important to the theory of duty since that theory, in modern philosophy, characteristically assumes a strong doctrine of individual responsibility. That is, it assumes principles of culpability for wrongdoing that require, as conditions of justified blame, that the act of wrongdoing be one’s own and that it not be done innocently. Only moral agents are capable of meeting these conditions. And the presumption is that normal, adult human beings qualify as moral agents whereas small children and nonhuman animals do not. The study then focuses on those capacities that distinguish the former from the latter as responsible beings.

The main issue is whether the power of reason alone accounts for these capacities. On one side of the issue are philosophers like Kant who hold that it does. Reason, in their view, is both the pilot and the engine of moral agency. It not only guides one toward actions in conformity with one's duty, but it also produces the desire to do one's duty and can invest that desire with enough strength to overrule conflicting impulses of appetite and passion. On the other side are philosophers, such as Hume and Mill, who take reason to be one of several capacities that constitute moral agency. On their view, reason works strictly in the service of natural and sublimated desires, fears, and aversions to produce intelligent action, to guide its possessor toward the objects of those desires and away from the objects of those fears. It cannot, however, by itself originate any desire or fear. Thus, the desire to act rightly, the aversion to acting wrongly, which are constituents of moral agency, are not products of reason but are instead acquired through some mechanical process of socialization by which their objects become associated with the objects of natural desires and aversions. On one view, then, moral agency consists in the power of reason to govern behavior, and being rational is thus sufficient for being responsible for one's actions. On the other view, moral agency consists in several things including reason, but also including a desire to act rightly and an aversion to acting wrongly that originate in natural desires and aversions. On this view, to be responsible for one's actions, one must not only be rational but also have certain desires and aversions whose acquisition is not guaranteed by the maturation of reason. Within moral psychology, one cardinal test of these views is how well they can accommodate and explain such common experiences of moral agency as conscience, weakness, and moral dilemma.

At some point, however, the views must be tested by questions about freedom. For one cannot be responsible for one's actions if one is incapable of acting freely, which is to say, of one's own free will. The capacity for free action is thus essential to moral agency, and how this capacity is to be explained, whether it fits within a deterministic universe, and if not, whether the notion of moral responsibility should be jettisoned, are among the deepest questions that the student of moral agency must face. What is more, they are not questions to which moral psychology can furnish answers. At this point, ethics descends into metaphysics.

ethics of citizenship, the area of investigation concerned with obligations of citizens as such, especially with duties they owe each other simply in virtue of being compatriots. These are often thought to include duties of assistance and of "patriotic" concern. Some have argued further that duties of *justice* are possible only among compatriots. In democratic theory, the ethics of citizenship concerns moral questions arising from the fact that democratic citizens, being political equals, with an equal share of decision-making power as voters, exercise a distinctive form of power over each other. Since political power is fundamentally coercive, citizenship involves potential coercion of one's equals. Citizenship thus involves distinctive responsibilities, and the conduct of citizens can be normatively evaluated.

Theorists associated with *participatory* or *civic republican* conceptions of democracy propose an ethic of citizenship requiring significant levels of civic engagement, interaction, and even activism. For liberal deliberative democrats, the ethics of citizenship focuses on the kinds of reasons citizens may appeal to when deliberating about politics and voting. These concerns arise from the fact that in a democratic society coercive government action must be justifiable to all citizens, including both the religious and the secular. Given that the freedoms secured in a democratic society produce a pluralism of distinctive moral viewpoints, it seems that when the state coerces it must be able to cite reasons for its action that each citizen could recognize. Hence the reasons of state cannot be sectarian: the state cannot rightly act on the basis of reasons whose force depends upon the acceptance of a religious or moral viewpoint that citizens are free to reject. But if it would be unjustified for the state to coerce citizens on the basis of reasons that are not shareable by all, then it would be wrong for an individual citizen to vote solely on the basis of her sectarian reasons. Thus democracy requires citizens to constrain their civic action as well as their contributions to public deliberation in various ways. The challenge is to show how this doctrine can itself be justifiable to all citizens.

ethics of love, an ethics that seeks to elaborate the idea that love of God and neighbor is the foundation of all morality or, if non-theistic, takes the right kind of love to play that foundational role. Jesus said, “Thou shalt love the Lord thy God with all thy heart. . . . And . . . thou shalt love thy neighbor as thyself. On these two commandments hang all the law and the prophets” (Matthew 22:37–40). This suggests the idea that love of God and neighbor is the foundation of all morality. An ethics of love seeks to elaborate this notion. If an ethics of love is supposed to be comprehensive, “my neighbor” must be “everyone” or “everyone I encounter.” Although different thinkers give accounts of love, they agree that love is essentially an attitude, but also involves action. One cannot truly be said to love others if one consistently neglects their needs. This suggests that an ethics of love is highly demanding – particularly if we take literally the idea of loving one’s neighbor *as oneself*.

Philosophers have wondered whether an ethics of love would be sufficiently determinate. Would it provide answers to ethical dilemmas – e.g., choices between killing and letting die, or concerning how to choose between the interests of two different people? If I am supposed to love each of my neighbors as myself, this suggests a sort of equality in my concern for each. This in turn would suggest helping the more needy first, or helping the one I could benefit more. Perhaps a Rawlsian veil of ignorance would help in making concrete decisions in light of one’s equal love for all.

A further issue raised by this morality concerns our obligations to future people. Consider a choice that bears on the welfare of future generations, but also makes a difference to the *identity* of the people who will exist in those generations – say, in choosing how many environmental protections to lobby for. If we choose practices that harm the environment and thereby make the world a worse place for future generations, there is probably no particular person who, 100 years from now, is harmed. It is tricky, if not impossible, for an ethics of love to explain what is wrong with this intuitively objectionable behavior. Such questions and challenges do not undermine the powerful appeal of an ethics of love, but provide fertile ground for hard labor.

See also COSMOPOLITANISM, EMOTION, EQUALITY, ETHICS, POLITICAL PHILOSOPHY. F.H.-S.

ethnography, an open-ended family of techniques through which anthropologists investigate cultures; also, the organized descriptions of other cultures that result from this method. Cultural anthropology – *ethnology* – is based primarily on fieldwork through which anthropologists immerse themselves in the life of a local culture (e.g., in a village or neighborhood) and attempt to describe and interpret aspects of the culture. Careful observation is one central tool of investigation. Through it anthropologists can record various features of social life, e.g. trading practices, farming techniques, or marriage arrangements. A second central tool is the interview, through which the researcher explores the beliefs and values of members of the local culture. Tools of historical research, including particularly oral history, are also of use in ethnography, since the cultural practices of interest often derive from a remote point in time. **See also** ETHNOLOGY.

D.E.L.

ethnology, the comparative and analytical study of cultures; cultural anthropology. Anthropologists aim to describe and interpret aspects of the culture of various social groups – e.g., the hunter-gatherers of the Kalahari, rice villages of the Chinese Canton Delta, or a community of physicists at Livermore Laboratory. Topics of particular interest include religious beliefs, linguistic practices, kinship arrangements, marriage patterns, farming technology, dietary practices, gender relations, and power relations. Cultural anthropology is generally conceived as an empirical science, and this raises several methodological and conceptual difficulties. First is the role of the observer. The injection of an alien observer into the local culture unavoidably disturbs it. Second, there is the problem of intelligibility across cultural systems – *radical translation*. One goal of ethnographic research is to arrive at an interpretation of a set of beliefs and values that are thought to be radically different from the researcher’s own beliefs and values; but if this is so, then it is questionable whether they are accurately translatable into the researcher’s conceptual scheme. Third, there is the problem of empirical testing of ethnographic interpretations. To what extent do empirical procedures constrain the construction of an interpretation of a given cultural milieu? Finally, there is the problem of generalizability. To what extent does fieldwork in one location permit anthropologists to generalize to a larger context – other villages, the dispersed ethnic group represented by this village, or this village at other times? **See also** ETHNOGRAPHY, PHILOSOPHY OF THE SOCIAL SCIENCES. D.E.L.

ethnomethodology, a phenomenological approach to interpreting everyday action and speech in various social contexts. Derived from phenomenological sociology and introduced by Harold Garfinkel, the method aims to guide research into meaningful social practices as experienced by participants. A major objective of the method is to interpret the rules that underlie everyday activity and thus constitute part of the normative basis of a given social order. Research from this perspective generally focuses on mundane social activities – e.g., psychiatrists evaluating patients' files, jurors deliberating on defendants' culpability, or coroners judging causes of death. The investigator then attempts to reconstruct an underlying set of rules and ad hoc procedures that may be taken to have guided the observed activity. The approach emphasizes the *contextuality* of social practice – the richness of unspoken shared understandings that guide and orient participants' actions.

Eucken, Rudolf. See LEBENSPHILOSOPHIE.

Euclid. See EUCLIDEAN GEOMETRY.

Euclidean geometry, the version of geometry that includes among its axioms the parallel axiom, which asserts that, given a line *L* in a plane, there exists just one line in the plane that passes through a point not on *L* but never meets *L*. The phrase 'Euclidean geometry' refers both to the doctrine of geometry to be found in Euclid's *Elements* (fourth century B.C.) and to the mathematical discipline that was built on this basis afterward. In order to present properties of rectilinear and curvilinear curves in the plane and solids in space, Euclid sought definitions, axioms, and postulates to ground the reasoning. Some of his assumptions belonged more to the underlying logic than to the geometry itself. Of the specifically geometrical axioms, the least self-evident stated that only one line passes through a point in a plane parallel to a non-coincident line within it, and many efforts were made to prove it from the other axioms. Notable forays were made by G. Saccheri, J. Playfair, and A. M. Legendre, among others, to put forward results logically contradictory to the parallel axiom (e.g., that the sum of the angles between the sides of a triangle is greater than 180°) and thus standing as candidates for falsehood; however, none of them led to paradox. Nor did logically equivalent axioms (such as that the angle sum equals 180°) seem to be more or less evident than the axiom itself. The next stages of this line of reasoning led to non-Euclidean geometry.

From the point of view of logic and rigor, Euclid was thought to be an apotheosis of certainty in human knowledge; indeed, 'Euclidean' was also used to suggest certainty, without any particular concern with geometry. Ironically, investigations undertaken in the late nineteenth century showed that, quite apart from the question of the parallel axiom, Euclid's system actually depended on more axioms than he had realized, and that filling all the gaps would be a formidable task. Pioneering work done especially by M. Pasch and G. Peano was brought to a climax in 1899 by Hilbert, who produced what was hoped to be a complete axiom system. (Even then the axiom of continuity had to wait for the second edition!) The endeavor had consequences beyond the Euclidean remit; it was an important example of the growth of axiomatization in mathematics as a whole, and it led Hilbert himself to see that questions like the consistency and completeness of a mathematical theory must be asked at another level, which he called metamathematics. It also gave his work a formalist character; he said that his axiomatic talk of points, lines, and planes could be of other objects.

Within the Euclidean realm, attention has fallen in recent decades upon "neo-Euclidean" geometries, in which the parallel axiom is upheld but a different metric is proposed. For example, given a planar triangle *ABC*, the Euclidean distance between *A* and *B* is the hypotenuse *AB;* but the "rectangular distance" *AC* + *CB* also satisfies the properties of a metric, and a geometry working with it is very useful in, e.g., economic geography, as anyone who drives around a city will readily understand.

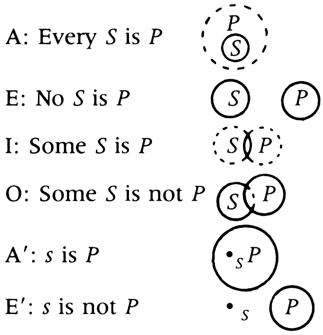
eudaimonia. See ARISTOTLE, EUDAIMONISM.

eudaimonism (from Greek *eudaimonia*, 'happiness', 'flourishing'), the ethical doctrine that happiness is the ultimate justification for morality. The ancient Greek philosophers typically begin their ethical treatises with an account of happiness, and then argue that the best way to achieve a happy life is through the cultivation and exercise of virtue. Most of them make virtue or virtuous activity a constituent of the happy life; the Epicureans, however, construe happiness in terms of pleasure, and treat virtue as a means to the end of pleasant living. Ethical eudaimonism is sometimes combined with psychological eudaimonism – i.e., the view that all free, intentional action is aimed ultimately at the agent's happiness. A common feature of ancient discussions of ethics, and one distinguishing them from most modern discussions, is the view that an agent would not be rationally justified in a course of action that promised less happiness than some alternative open to him. Hence it seems that most of the ancient theories are forms of egoism. But the ancient theories differ from modern versions of egoism since, according to the ancients, at least some of the virtues are dispositions to act from primarily other-regarding motives: although the agent's happiness is the ultimate justification of virtuous action, it is not necessarily what motivates such action. Since happiness is regarded by most of the ancients as the ultimate *end* that justifies our actions, their ethical theories seem teleological; i.e., right or virtuous action is construed as action that contributes to or maximizes the good. But appearances are again misleading, for the ancients typically regard virtuous action as also valuable for its own sake and hence *constitutive* of the agent's happiness. **See also** EGOISM, ETHICS, HEDONISM, UTILITARIANISM. D.T.D.

Eudoxus of Cnidus (c.408–c.355 B.C.), Greek astronomer and mathematician, a student of Plato. He created a test of the equality of two ratios, invented the method of exhaustion for calculating areas and volumes within curved boundaries, and introduced an astronomical system consisting of homocentric celestial spheres. This system views the visible universe as a set of twenty-seven spheres contained one inside the other and each concentric to the earth. Every celestial body is located on the equator of an ideal sphere that revolves with uniform speed on its axis. The poles are embedded in the surface of another sphere, which also revolves uniformly around an axis inclined at a constant angle to that of the first sphere. In this way enough spheres are introduced to capture the apparent motions of all heavenly bodies. Aristotle adopted the system of homocentric spheres and provided a physical interpretation for it in his cosmology. R.E.B.

Euler diagram, a logic diagram invented by the mathematician Euler that represents standard form statements in syllogistic logic by two circles and a syllogism by three circles. In modern adaptations of Euler diagrams, distributed terms are represented by complete circles and undistributed terms by partial circles (circle segments or circles made with dotted lines):



Euler diagrams are more perspicuous ways of showing validity and invalidity of syllogisms than Venn diagrams, but less useful as a mechanical test of validity since there may be several choices of ways to represent a syllogism in Euler diagrams, only one of which will show that the syllogism is invalid. **See also** SYLLOGISM, VENN DIAGRAM. R.P.

Eurytus of Croton. See PRE-SOCRATICS.

euthanasia, broadly, the beneficent timing or negotiation of the death of a sick person; more narrowly, the killing of a human being on the ground that he is better off dead. In an extended sense, 'euthanasia' designates the painless killing of non-human animals, in our interests at least as much as in theirs.

Active euthanasia is the taking of steps to end a person's – especially a patient's – life. *Passive euthanasia* is the omission or termination of means of prolonging life, on the ground that the person is better off without them. The distinction between active and passive euthanasia is a rough guide for applying the more fundamental distinction between intending the patient's death and pursuing other goals, such as the relief of her pain, with the expectation that she will die sooner rather than later as a result.

Voluntary euthanasia is euthanasia with the patient's consent, or at his request. *Involuntary euthanasia* is euthanasia over the patient's objections. *Non-voluntary euthanasia* is the killing of a person deemed incompetent with the consent of someone – say a parent – authorized to speak on his behalf. Since candidates for euthanasia are frequently in no condition to make major decisions, the question whether there is a difference between involuntary and non-voluntary euthanasia is of great importance.

Few moralists hold that life must be prolonged whatever the cost. Traditional morality forbids directly intended euthanasia: human life belongs to God and may be taken only by God. The most important grounds for euthanasia are the pain and indignity suffered by those with incurable diseases, the burden imposed by persons unable to take part in normal human activities, and the supposed right of persons to dispose of their lives however they please. Non-theological arguments against euthanasia include the danger of expanding the principle of euthanasia to an ever-widening range of persons and the opacity of death and its consequent incommensurability with life, so that we cannot safely judge that a person is better off dead.

Euthyphro problem (formulated in Plato's dialogue, *Euthyphro*), a problem concerning the center of gravity for normative values: do these lie in the thing valued or originate with those who attribute value to the thing? Although Socrates has moral values generally in mind (which make actions just or unjust, good or bad, right or wrong), his discussion with Euthyphro focuses on a specific religious value variously translated as 'piety' or 'holiness'. They both agree that piety is loved or favored by the gods. For Euthyphro, a man of strong religious commitments, having divine favor is both the measure and the very meaning of an action's piety. For Socrates, however, it is *because* the action itself is pious that the gods love and approve it. As in many of Plato's dialogues, the search is for a definition. Socrates wants to know the nature of piety, what makes it so, implying that divine favor is strictly consequential, if not secondary. Ironically, despite having boasted about his enlightened knowledge of such matters, Euthyphro cannot furnish an adequate definition.

Socrates' question was not posed as a dilemma, but many have framed it as a philosophical conundrum for Western monotheists called the "divine command problem." What gives authority to God's commandments? What is the scope of the divine will? If an omnipotent God *determines* which actions are right and which are wrong, then it seems within God's power to reverse the poles of value. Cruelty might suddenly become right and mercy wrong. On the other hand, if the values of actions are intrinsic or transcendent and unchangeable, then God is not omnipotent. Since the gods in Greek religion were held to disapprove of each other's conduct, Plato was understandably inclined to look for an impersonal account of moral value, but in any monotheistic system where God plays an active and central role, the customary solution to the conundrum takes God as omnibenevolent, the very source of moral value, and in effect grounds ethical concepts on religious doctrine. A common response sees this answer as more an entanglement than a solution, perhaps even as compromising human freedom and integrity. If we can judge some actions to be right and others wrong regardless of our theological commitments, doesn't philosophy have the job of charting another course? One such alternative locates the source of moral value in human rather than divine will. Another identifies value with universal social conventions that constrain the individual agent without transcending humanity itself. Such proposals suggest that the underlying issue in the divine command problem concerns the proper territory of metaphysics, specifically whether it includes philosophical theology. However, this is not the heart of the Euthyphro problem. Plato recognized the unavoidable tension between subjective and objective conceptions of value. The tension persists and must be managed whether the source of authority is construed as divine or human.

event, anything that happens; an occurrence. Two fundamental questions about events, which philosophers have usually treated together, are: (1) Are there events? (2) If so, what is their nature? Some philosophers simply assume that there are events. Others argue for that, typically through finding semantic theories for ordinary claims that apparently concern the fact that some agent has done something or that something has changed.

Most philosophers presume that the events whose existence is proved by such arguments are abstract particulars, "particulars" in the sense that they are non-repeatable and spatially locatable, "abstract" in the sense that more than one event can occur simultaneously in the same place. The theories of events espoused by Davidson (in his causal view), Kim (though his view may be unstable in this respect), Jonathan Bennett, and Lawrence Lombard take them to be abstract particulars. However, Chisholm takes events to be abstract universals; and Quine and Davidson (in his later view) take them to be concrete particulars.

Some philosophers who think of events as abstract particulars tend to associate the concept of an event with the concept of *change;* an event is a change in some object or other (though some philosophers have doubts about this and others have denied it outright). The time at which an event, construed as a particular, occurs can be associated with the (shortest) time at which the object, which is the subject of that event, changes from the having of one property to the having of another, contrary property. Events inherit whatever spatial locations they have from the spatial locations, if any, of the things that those events are changes in. Thus, an event that is a change in an object, x, from being F to being G is located wherever x is at the time it changes from being F to being G.

Some events are those of which another event is composed (e.g., the sinking of a ship seems composed of the sinkings of its parts). However, it also seems clear that not every group of events comprises another; there just is no event composed of a certain explosion on Venus and my birth.

Any adequate theory about the nature of events must address the question of what properties, if any, such things have essentially. One issue is whether the causes (or effects) of events are essential to those events. A second is whether it is essential to each event that it be a change in the entity it is in fact a change in. A third is whether it is essential to each event that it occur at the time at which it in fact occurs.

A chief component of a theory of events is a *criterion of identity*, a principle giving conditions necessary and sufficient for an event e and an event e' to be one and the same event. Quine holds that events may be identified with the temporal parts of physical objects, and that events and physical objects would thus share the same condition of identity: sameness of spatiotemporal location. Davidson once proposed that events are identical provided they have the same causes and effects. More recently, Davidson abandoned this position in favor of Quine's.

Kim takes an event to be the exemplification of a property (or relation) by an object (or objects) at a time. This idea has led to his view that an event e is the same as an event e' if and only if e and e' are the exemplifications of the same property by the same object(s) at the same time. Lombard's view is a variation on this account, and is derived from the idea of events as the changes that physical objects undergo when they alter.

evidence, information bearing on the truth or falsity of a proposition. In philosophical discussions, a person's evidence is generally taken to be all the information a person has, positive or negative, relevant to a proposition. The notion of evidence used in philosophy thus differs from the ordinary notion according to which physical objects, such as a strand of hair or a drop of blood, count as evidence. One's information about such objects could be evidence in the philosophical sense.

The concept of evidence plays a central role in our understanding of knowledge and rationality. According to a traditional and widely held view, one has knowledge only when one has a true belief based on very strong evidence. Rational belief is belief based on adequate evidence, even if that evidence falls short of what is needed for knowledge. Many traditional philosophical debates, such as those about our knowledge of the external world, the rationality of religious belief, and the rational basis for moral judgments, are largely about whether the evidence we have in these areas is sufficient to yield knowledge or rational belief.

The senses are a primary source of evidence. Thus, for most, if not all, of our beliefs, ultimately our evidence traces back to sensory experience. Other sources of evidence include memory and the testimony of others. Of course, both of these sources rely on the senses in one way or another. According to rationalist views, we can also get evidence for some propositions through mere reason or reflection, and so reason is an additional source of evidence. The evidence one has for a belief may be conclusive or inconclusive. Conclusive evidence is so strong as to rule out the possibility of error. The discussions of skepticism show clearly that we lack conclusive evidence for our beliefs about the external world, about the past, about other minds, and about nearly any other topic. Thus, an individual's perceptual experiences provide only inconclusive evidence for beliefs about the external world since such experiences can be deceptive or hallucinatory. Inconclusive, or prima facie, evidence can always be defeated or overridden by subsequently acquired evidence, as, e.g., when testimonial evidence in favor of a proposition is overridden by the evidence provided by subsequent experiences.

See also EPISTEMOLOGY, SKEPTICISM. R.Fe.

evidence of the senses. See EVIDENCE.

evidentialism, in philosophy of religion, the view that religious beliefs are rationally acceptable only if they are supported by one's "total evidence," understood to mean all the other propositions one knows or justifiably believes to be true. Evidentialists typically add that, in order to be rational, one's degree of belief should be proportioned to the strength of the evidential support. Evidentialism was formulated by Locke as a weapon against the sectarians of his day and has since been used by Clifford (among many others) to attack religious belief in general. A milder form of evidentialism is found in Aquinas, who, unlike Clifford, thinks religion can meet the evidentialist challenge.

A contrasting view is *fideism*, best understood as the claim that one's fundamental religious convictions are not subject to independent rational assessment. A reason often given for this is that devotion to God should be one's "ultimate concern," and to subject faith to the judgment of reason is to place reason above God and make of it an idol. Proponents of fideism include Tertullian, Kierkegaard, Karl Barth, and some Wittgensteinians.

A third view, which as yet lacks a generally accepted label, may be termed *experientialism;* it asserts that some religious beliefs are directly justified by religious experience. Experientialism differs from evidentialism in holding that religious beliefs can be rational without being supported by inferences from other beliefs one holds; thus theistic arguments are superfluous, whether or not there are any sound ones available. But experientialism is not fideism; it says that religious beliefs may be directly grounded in religious experience without the mediation of other beliefs, and may be rationally warranted on that account, just as perceptual beliefs are directly grounded in perceptual experience. Recent examples of experientialism are found in Plantinga's "Reformed Epistemology," on which religious beliefs grounded in experience can be "properly basic," and in the contention of Alston that in religious experience the subject may be "perceiving God."

evidential reason. See EPISTEMOLOGY.

evil, like badness, refers to that which should not be, including behavior and states of character that are blameworthy or warrant negative evaluation. Some philosophers consider evil a cosmic, powerful reality. In Zoroastrianism, evil is portrayed as a force of darkness and destruction (*Angra Mainyu* or *Ahriman*). Gnosticism, a Mediterranean movement during the first century (possibly earlier), included teachings that the material world is itself the creation of an evil power. Manichaeism (third century A.D.) sees creation as an evil. At the other extreme, some philosophers construe evil (as well as goodness) as a subjective projection reflecting what human persons are averse to or find abominable.

In some forms of Buddhism and Daoism, there are vices and prohibitions; arguably, however, these are matters of balance and imbalance, but not of evil insofar as that is a profound violation of the will of God or a kind of sacrilege. Among the questions about evil prompting extensive philosophical work is whether it could be a privation of good. Severe suffering is a positive real state, but might it still be a kind of deprivation of a good, the dysfunction or injury of being which should, ideally, be healthy? Moreover, would there be evil if there were no conscious beings? Can one knowingly and freely choose to do what one genuinely believes to be evil? If there is an all-powerful, all-good, all-knowing God, why does evil exist? And can its effects somehow be defeated by repentance or restitution? Granted that evil and badness are scalar terms (one thing may be more evil than another), are there differences in kinds of evil, e.g. between moral evils (such as murder) and natural evils (such as diseases that kill thousands). Are there absolute evils, events that are so evil that there can be no justification for causing or not preventing such evil?

evil, problem of. See PHILOSOPHY OF RELIGION.

evolution. See DARWINISM.

evolutionary arguments, arguments that address philosophical questions while employing at least one premise concerning evolutionary history. The range of arguments satisfying this criterion is extremely varied and open-ended. The following are examples.

An evolutionary argument against naturalism (which in this context is roughly the idea that there is no God) first observes that Darwinian selection is not interested in providing organisms with true beliefs, but rather with reproductively advantageous beliefs. Thus (it is argued) the combination of the thesis of naturalism and the fact that humans have evolved through a process of natural selection implies that the probability of our cognitive faculties being reliable is low.

An evolutionary argument against psychological egoism contends that (a) Darwinian selection will tend to achieve reproductively beneficial ends by the most simple and economical means, (b) humans are designed to cooperate in certain circumstances (e.g., in raising offspring), and (c) a faculty of caring directly for the welfare of another is likely to be a simpler and more economical mechanism for prompting cooperative behavior than an egoistic mechanism (whereby agents will be moved only if they can see some self-gain in cooperating).

An evolutionary argument has been used to provide an account of mental intentionality. On this view, certain psychological states are about certain states of affairs (e.g., a belief is about London's being the capital of the United Kingdom) in virtue of the mechanisms involved operating in accordance with their evolutionary function. A quite different evolutionary argument attacks moral realism. If one supposes that Darwinian selection has shaped the human moral faculty, then the moral realist faces the task of explaining the relation between our moral judgments and the realm of objective moral facts. If there is no connection, then the chances that our judgments are close to being true seem extremely low; but the alternative proposal – that our evolved moral faculty "tracks" real moral properties – seems empirically dubious (or so it is claimed) in light of the plausible hypothesis that the adaptiveness of the human moral sense lies in its contribution to enhancing social bonds rather than tracking truths.

Evolutionary arguments appear throughout philosophy: in ethics, epistemology, metaphysics, philosophy of mind, and aesthetics. Those referred to here are just a small sample of the many that could be mentioned.

See also DARWINISM, NEUROETHICS, PHILOSOPHY OF BIOLOGY. R.Jo.

evolutionary epistemology, a theory of knowledge inspired by and derived from the fact and processes of organic evolution (the term was coined by the social psychologist Donald Campbell). Most evolutionary epistemologists subscribe to the theory of evolution through natural selection, as presented by Darwin in the *Origin of Species* (1859). However, one does find variants, especially one based on some kind of neo-Lamarckism, where the inheritance of acquired characters is central (Spencer endorsed this view) and another based on some kind of jerky or "saltationary" evolutionism (Kuhn, at the end of *The Structure of Scientific Revolutions*, accepts this idea).

There are two approaches to evolutionary epistemology. First, one can think of the transformation of organisms and the processes driving such change as an *analogy* for the growth of knowledge, particularly scientific knowledge. "Darwin's bulldog," T. H. Huxley, was one of the first to propose this idea. He argued that just as between organisms we have a struggle for existence, leading to the selection of the fittest, so between scientific ideas we have a struggle leading to a selection of the fittest. Notable exponents of this view today include Stephen Toulmin, who has worked through the analogy in some detail, and David Hull, who brings a sensitive sociological perspective to bear on the position. Popper identifies with this form of evolutionary epistemology, arguing that the selection of ideas is his view of science as bold conjecture and rigorous attempts at refutation by another name.

The problem with this analogical type of evolutionary epistemology lies in the disanalogy between the raw variants of biology (mutations), which are random, and the raw variants of science (new hypotheses), which are very rarely random. This difference probably accounts for the fact that whereas Darwinian evolution is not genuinely progressive, science is (or seems to be) the paradigm of a progressive enterprise. Because of this problem, a second set of epistemologists inspired by evolution insist that one must take the biology *literally*. This group, which includes Darwin, who speculated in this way even in his earliest notebooks, claims that evolution predisposes us to think in certain fixed adaptive patterns. The laws of logic, e.g., as well as mathematics and the methodological dictates of science, have their foundations in the fact that those of our would-be ancestors who took them seriously survived and reproduced, and those that did not did not. No one claims that we have innate knowledge of the kind demolished by Locke. Rather, our thinking is channeled in certain directions by our biology. In an update of the biogenetic law, therefore, one might say that whereas a claim like 5 + 7 = 12 is phylogenetically a posteriori, it is ontogenetically a priori.

A major division in this school is between the Continental evolutionists, most notably the late Konrad Lorenz, and the Anglo-Saxon supporters, e.g. Michael Ruse. The former think that their evolutionary epistemology simply updates the critical philosophy of Kant, and that biology both explains the necessity of the synthetic a priori and makes reasonable belief in the thing-in-itself. The latter deny that one can ever get that necessity, certainly not from biology, or that evolution makes reasonable a belief in an objectively real world, independent of our knowing. Historically, these epistemologists look to Hume and in some respects to the American pragmatists, especially James. Today, they acknowledge a strong family resemblance to such naturalized epistemologists as Quine, who has endorsed a kind of evolutionary epistemology.

Critics of this position, e.g. Kitcher, usually strike at what they see as the soft scientific underbelly. They argue that the belief that the mind is constructed according to various innate adaptive channels is without warrant. It is but one more manifestation of today's Darwinians illicitly seeing adaptation everywhere. It is better and more reasonable to think knowledge is rooted in culture, if it is person-dependent at all.

A mark of a good philosophy, like a good science, is opening up new avenues for research. Although evolutionary epistemology is not favored by conventional philosophers, who sneer at the crudities of its (frequently non-philosophically trained) proselytizers, its supporters feel convinced that they are contributing to a forward-moving philosophical research program. As evolutionists, they are used to things taking time to succeed.

See also DARWINISM, EPISTEMOLOGY, PHILOSOPHY OF BIOLOGY, SOCIAL BIOLOGY. M.Ru.

evolutionary ethics, an empirically informed subfield of moral philosophy that seeks to support or undermine certain normative or metaethical theses on the basis of data concerning Darwinian evolution. Sometimes just the empirical investigation of the evolved basis of human social nature is called "evolutionary ethics," though one might prefer to call this "empirical evolutionary ethics," in contrast to "philosophical evolutionary ethics," which aspires to use descriptive evidence to address some questions of moral philosophy.

Philosophical evolutionary ethics can have a positive or negative flavor. The more positive projects attempt to vindicate particular moral theories or judgments on the basis of evolutionary theory. Herbert Spencer endorsed a progressive view of evolution, identifying goodness with that which is "more evolved" and arguing that laissez-faire social policies are the natural consequence. Other moral philosophers, seeking to base an account of human virtues on human nature, attempt to replace the flawed Aristotelian teleological view of humans with a scientifically respectable Darwinian view. Alternatively, one might argue that if the human moral sense is the product of evolution, it must have a natural function, and that this function continues to constrain how we should use this sense in decision making. Another positive program discredits deontological moral intuitions on the grounds that they are the output of psychological mechanisms that operated adaptively in the Pleistocene environment but now respond to factors that are not morally relevant. Despite its discrediting move, this project can count as "positive" insofar as it champions the consequentialism that remains once deontological intuitions are rejected.

Positive philosophical evolutionary ethics is accused of trying to derive an 'ought' from an 'is' (something often incorrectly called "committing the naturalistic fallacy"). However, it is dubious that an advocate of such a view proposes to argue for an 'ought' conclusion using only descriptive premises. Moreover, if evolutionary ethics were to support a *metaethical* thesis, this would not support an 'ought' claim (but rather, perhaps, support a thesis about the nature of 'ought' claims).

The negative side of evolutionary ethics is illustrated by a number of arguments that attempt to debunk morality or overturn widely accepted moral theories. An evolved moral sense, it is argued, delivered a reproductive advantage to our ancestors quite independently of providing them any access to moral truths. One might think that this seriously weakens the epistemic status of our moral judgments, or alternatively argue that moral realism is consequently undermined.

evolutionary psychology, the subfield of psychology that explains human behavior and cultural arrangements by employing evolutionary biology and cognitive psychology to discover, catalog, and analyze psychological mechanisms. Human minds allegedly possess many innate, special-purpose, domain-specific psychological mechanisms (modules) whose development requires minimal input and whose operations are context-sensitive, mostly automatic, and independent of one another and of general intelligence. (Disagreements persist about the functional isolation and innateness of these modules.) Some evolutionary psychologists compare the mind – with its specialized modules – to a Swiss army knife. Different modules substantially constrain behavior and cognition associated with language, sociality, face recognition, etc.

Evolutionary psychologists emphasize that psychological phenomena reflect the influence of biological evolution. These modules and associated behavior patterns assumed their forms during the Pleistocene. An evolutionary perspective identifies adaptive problems and features of the Pleistocene environment that constrained possible solutions. Adaptive problems often have cognitive dimensions. For example, an evolutionary imperative to aid kin presumes the ability to detect kin. Evolutionary psychologists propose models to meet the requisite cognitive demands. Plausible models should produce adaptive behaviors and avoid maladaptive ones – e.g., generating too many false positives when identifying kin. Experimental psychological evidence and social scientific field observations aid assessment of these proposals.

These modules have changed little. Modern humans manage with primitive hunter-gatherers' cognitive equipment amid the rapid cultural change that equipment produces. The pace of that change outstrips the ability of biological evolution to keep up. Evolutionary psychologists thus hold that (1) contrary to sociobiology, which appeals to biological evolution directly, exclusively evolutionary explanations of human behavior will not suffice; (2) contrary to theories of cultural evolution, which appeal to biological evolution analogically, it is at least possible that no cultural arrangement has ever been adaptive; and (3) contrary to social scientists, who appeal to some general conception of learning or socialization to explain cultural transmission, specialized psychological mechanisms contribute substantially to that process.

existential generalization, a rule of inference admissible in classical quantification theory. It allows one to infer an existentially quantified statement $\exists xA$ from any instance $A(a/x)$ of it. (Intuitively, it allows one to infer 'There exists a liar' from 'Epimenides is a liar'.) It is equivalent to universal instantiation – the rule that allows one to infer any instance $A(a/x)$ of a universally quantified statement $\forall xA$ from $\forall xA$. (Intuitively, it allows one to infer 'My car is valuable' from 'Everything is valuable'.) Both rules can also have equivalent formulations as axioms; then they are called specification ($\forall xA \supset A(a/x)$) and particularization ($(A(a/x) \supset \exists xA$). All of these equivalent principles are denied by free logic, which admits only weakened versions of them. In the case of existential generalization, the weakened version is: infer $\exists xA$ from $A(a/x)$ & $E!a$. (Intuitively, infer 'There exists a liar' from 'Epimenides is a liar and Epimenides exists'.) **See also** EXISTENTIAL INSTANTIATION, FORMAL LOGIC, FREE LOGIC, UNIVERSAL INSTANTIATION. E.Ben.

existential graph. See PEIRCE.

existential import, a commitment to the existence of something implied by a sentence, statement, or proposition. For example, in Aristotelian logic (though not in modern quantification theory), any sentence of the form 'All *F*'s are *G*'s' implies 'There is an *F* that is a *G*' and is thus said to have as existential import a commitment to the existence of an *F* that is a *G*. According to Russell's theory of descriptions, sentences containing definite descriptions can likewise have existential import since 'The *F* is a *G*' implies 'There is an *F*'. The presence of singular terms is also often claimed to give rise to existential commitment. Underlying this notion of existential import is the idea – long stressed by Quine – that ontological commitment is measured by *existential sentences* (*statements, propositions*) of the form $(\exists v)\phi$. **See also** ONTOLOGICAL COMMITMENT. G.F.S.

existential instantiation, a rule of inference admissible in classical quantification theory. It allows one to infer a statement *A* from an existentially quantified statement $\exists xB$ if *A* can be inferred from an instance $B(a/x)$ of $\exists xB$, provided that *a* does not occur in either *A* or *B* or any other premise of the argument (if there is any). (Intuitively, it allows one to infer a contradiction *C* from 'There exists a highest prime' if *C* can be inferred from '*a* is a highest prime' and *a* does not occur in *C*.) Free logic allows for a stronger form of this rule: with the same provisions as above, *A* can be inferred from $\exists xB$ if it can be inferred from $B(a/x)$ & E!*a*. (Intuitively, it is enough to infer 'There is a highest natural number' from '*a* is a highest prime and *a* exists'.) **See also** FORMAL LOGIC, FREE LOGIC. E.Ben.

existentialism, a philosophical and literary movement that came to prominence in Europe, particularly in France, immediately after World War II, and that focused on the uniqueness of each human individual as distinguished from abstract universal human qualities. Historians differ as to antecedents. Some see an existentialist precursor in Pascal, whose aphoristically expressed Catholic fideism questioned the power of rationalist thought and preferred the God of Scripture to the abstract "God of the philosophers." Many agree that Kierkegaard, whose fundamentally similar but Protestant fideism was based on a profound unwillingness to situate either God or any individual's relationship with God within a systematic philosophy, as Hegel had done, should be considered the first modern existentialist, though he too lived long before the term emerged. Others find a proto-existentialist in Nietzsche, because of the aphoristic and anti-systematic nature of his writings, and, on the literary side, in Dostoevsky. (A number of twentieth-century novelists, such as Franz Kafka, have been labeled existentialists.)

A strong existentialist strain is found in certain other theist philosophers who have written since Kierkegaard, such as Lequier, Berdyaev, Marcel, Jaspers, and Buber, but Marcel later decided to reject the label 'existentialist', which he had previously employed. This reflects its increasing identification with the atheistic existentialism of Sartre, whose successes, as in the novel *Nausea* and the philosophical work *Being and Nothingness*, did most to popularize the word. A mass-audience lecture, "Existentialism Is a Humanism," which Sartre (to his later regret) allowed to be published, provided the occasion for Heidegger, whose early thought had greatly influenced Sartre's evolution, to take his distance from Sartre's existentialism, in particular for its self-conscious concentration on human reality over Being. Heidegger's *Letter on Humanism*, written in reply to a French admirer, signals an important turn in his thinking. Nevertheless, many historians continue to classify Heidegger as an existentialist – quite reasonably, given his early emphasis on existential categories and ideas such as anxiety in the presence of death, our sense of being "thrown" into existence, and our temptation to choose anonymity over authenticity in our conduct. This illustrates the difficulty of fixing the term 'existentialism'. Other French thinkers of the time, all acquaintances of Sartre's, who are often classified as existentialists are Camus, Simone de Beauvoir, and, though with less reason, Merleau-Ponty.

Camus's novels, such as *The Stranger* and *The Plague*, are cited along with *Nausea* as epitomizing the uniqueness of the existentialist antihero who acts out of authenticity – i.e., in freedom from any conventional expectations about what so-called human nature (a concept rejected by Sartre) supposedly requires in a given situation, and with a sense of personal responsibility and absolute lucidity that precludes the "bad faith" or lying to oneself that characterizes most conventional human behavior. Good scholarship prescribes caution, however, about superimposing too many Sartrean categories on Camus. In fact the latter, in his brief philosophical essays, notably *The Myth of Sisyphus*, distinguishes existentialist writers and philosophers, such as Kierkegaard, from *absurdist* thinkers and heroes, whom he regards more highly and of whom the mythical Sisyphus (condemned eternally by the gods to roll a huge boulder up a hill before being forced, just before reaching the summit, to start anew) is the epitome. Camus focuses on the concept of the *absurd*, which Kierkegaard had used to characterize the object of his religious faith (an incarnate God). But for Camus existential absurdity lies in the fact, as he sees it, that there is always at best an imperfect fit between human reasoning and its intended objects, hence an impossibility of achieving certitude. Kierkegaard's leap of faith is, for Camus, one more pseudo-solution to this hard, absurdist reality.

Almost alone among those named besides Sartre (who himself concentrated more on social and political thought and became indebted to Marxism in his later years), Simone de Beauvoir (1908–86) unqualifiedly accepted the existentialist label. In *The Ethics of Ambiguity*, she attempted, using categories familiar in Sartre, to produce an existentialist ethics based on the recognition of radical human freedom as "projected" toward an open future, the rejection of inauthenticity, and a condemnation of the "spirit of seriousness" (akin to the "spirit of gravity" criticized by Nietzsche) whereby individuals identify themselves wholly with certain fixed qualities, values, tenets, or prejudices. Her feminist masterpiece, *The Second Sex*, relies heavily on the distinction, part existentialist and part Hegelian in inspiration, between a life of immanence, or passive acceptance of the role into which one has been socialized, and one of transcendence, actively and freely testing one's possibilities with a view to redefining one's future. Historically, women have been consigned to the sphere of immanence, says de Beauvoir, but in fact a woman in the traditional sense is not something that one is *made*, without appeal, but rather something that one *becomes*.

The Sartrean ontology of *Being and Nothingness*, according to which there are two fundamental asymmetrical "regions of being," being-in-itself and being-for-itself, the latter having no definable essence and hence, as "nothing" in itself, serving as the ground for freedom, creativity, and action, serves well as a theoretical framework for an existentialist approach to human existence. (*Being and Nothingness* also names a third ontological region, being-for-others, but that may be disregarded here.) However, it would be a mistake to treat even Sartre's existentialist insights, much less those of others, as dependent on this ontology, to which he himself made little direct reference in his later works. Rather, it is the implications of the common central claim that we human beings exist without justification (hence "absurdly") in a world into which we are "thrown," condemned to assume full responsibility for our free actions and for the very values according to which we act, that make existentialism a continuing philosophical challenge, particularly to ethicists who believe right choices to be dictated by our alleged human essence or nature.

experimental philosophy, philosophical work that addresses issues in philosophy by citing or performing scientific experiments. More narrowly, some commentators seem to count philosophers as experimental only if they perform experiments themselves rather than merely cite experiments by others. Even more narrowly, some observers associate experimental philosophy with a certain type of experiment, especially surveys about what people (usually including non-philosophers or common folk) say or think about philosophical issues. What makes any of this philosophy is that it uses such experiments to address issues in philosophy.

No matter how broadly construed, experimental philosophy contrasts with the method of a priori reflection, which tries to settle philosophical issues by intuition or conceptual analysis without basing philosophical claims on scientific discoveries. Experimental critics of this method often describe it as "armchair speculation." This a priori method is usually seen as more traditional, although many classic philosophers engaged in and with experimental science and experimental philosophers have questioned a priori methods at least as far back as the 1930s with Arne Naess and his followers.

Despite heated and sometimes vicious battles, these two methods are not exclusive. Non-experimental philosophers can admit both that science is relevant to at least some philosophical issues and also that some experimental results (such as framing effects) can cast doubt on some philosophical intuitions. On the other side, experimental philosophers need not (and perhaps could not) entirely avoid a priori reflection. Experimental philosophers often use experiments not to replace traditional philosophical reflection but, instead, to confirm a priori reflections or to raise doubts about certain reflections by themselves or others. Experiments can then complement reflection.

Defenders of traditional philosophy often accuse experimental philosophers of simple logical errors, but experimental philosophers do not have to argue directly from science to philosophy. They can admit the need for philosophical premises to supplement experimental results before deducing any philosophical conclusions. Experiments can then provide evidence without entailing philosophical conclusions. Coherentists can also see scientific findings as a significant part of the larger set of beliefs with which philosophical theories must cohere in order to be justified. Nonetheless, many experimental philosophers use experiments to question or deny traditional philosophical methods. They see themselves as burning the armchair of speculation. The most radical version of this critique claims that all a priori reflection by traditional philosophers is worthless because it merely reports idiosyncratic assumptions or prejudices of unusual individuals. Skeptics often add that certain philosophical views become popular only because they appeal to a few elite philosophers or cultures that happen to be dominant at the time. Less radical critics use experiments not against all traditional philosophy in general but only against a particular subset of philosophical theories, arguments, or issues.

When experimental philosophers focus on a particular issue, they sometimes take sides. They claim that the traditional philosophical debate can be resolved by science or that central arguments for one stand on the issue depend on questionable assumptions. An example occurs when incompatibilists claim that most people agree with them, so compatibilists must carry the burden of showing how determinism can be compatible with free will or responsibility. In response, some experimental philosophers cite experimental evidence that many or most people do not accept incompatibilism when it is properly presented and distinguished from close but distinct views, such as fatalism. They conclude that compatibilists do not have to carry any special burden of proof, and maybe incompatibilists do have to carry such a burden. Of course, other experimental philosophers cite their own experiments for the opposite claim, so the debate goes on.

In contrast, other experimental philosophers do not pick sides in traditional philosophical disagreements but, instead, try to dissolve those issues. One method uses experiments to refute a presupposition shared by both sides in the debate. For example, competing attempts to analyze the concept of knowledge in response to Gettier examples presuppose that there is a single unified concept to be analyzed. Some experiments suggest, however, that Asians might have a different concept than Europeans, and women might have a different concept than men. If so, then competing analyses can capture at most part of the truth for some people, but they cannot accurately represent a shared concept, as they claim. Many replies are available, of course, but this example still shows how experiments can be used to undermine a traditional debate without taking sides in that debate.

Another use of experiments aims to understand why philosophical paradoxes arise and seem so intractable. Some scientific findings and theories, such as dual-process theories, suggest that psychological tendencies deep in human nature – whether biology, culture, or both – attract most people to each of two (or more) incompatible positions on many philosophical issues. For example, many people have intuitions that horrific criminals are fully morally responsible, even though they also have other intuitions that point toward hard determinism and the denial of any real moral responsibility. When conflicting intuitions are built into us, no position on these philosophical issues will ever seem completely satisfying over time to most of us. The lesson drawn by this kind of experimental philosopher is that we need to learn to live with conflicting intuitions and paradoxes. The role of experimental philosophy is then to help us understand how we ended up in this mess.

experimentum crusis. See CRUCIAL EXPERIMENT.

expertise, superior skill or knowledge in a specific domain, of a kind that tends to distinguish one who possesses it as an authority with respect to that domain. In Western philosophy, an explicit concern with the topic dates at least to the ancient Greeks; for example, questions about the nature of expertise, how those who possess it can be reliably identified, and the range of domains in which genuine expertise is possible were raised and debated in Plato's dialogues.

The notion of expertise is particularly important for epistemology. Plausibly, any individual is dependent for much of what she knows on individuals whose expertise exceeds her own. While our dependence on experts is perhaps most obvious regarding beliefs about esoteric subjects, it is also manifested in beliefs as humdrum as those concerning tomorrow's weather. All else being equal, it makes sense for laypersons to defer to an expert forecaster's judgment that it will rain tomorrow, not only because the expert forecaster typically has meteorological data the layperson lacks, but also because the former has the capacity to understand and synthesize that data in such a way as to arrive at reliable predictions. In cases such as this, the exercise of expertise generates evidence or justification for believing a certain conclusion, evidence and justification that can be exploited by the non-expert. As pervasive and important as this phenomenon is, it is likely that our cognitive dependence on the expertise of others runs deeper still. Competent speakers of English can use 'beeches' to refer to beeches (and not elms) even if they cannot actually distinguish beech trees from elm trees; their ability to do this apparently depends on their belonging to a linguistic community some of whose members do possess arboreal expertise sufficient to distinguish beeches from elms. Similarly, the ability of the average person to so much as entertain thoughts about electrons apparently depends on the relations that she bears to others who have attained a sufficient level of scientific expertise. Thus, questions about the role of expertise in our cognitive lives are central not only for epistemology but also for the philosophies of language and mind.

Another cluster of issues concerns the range of domains in which genuine expertise exists or is possible. Could there be genuine *moral* experts? Could it be reasonable (or even rationally required) to simply outsource one's moral convictions to another person, as with weather forecasting? If not, what might this asymmetry show about morality? If there are full-blooded moral experts who stand to morality as scientific experts stand to their specialties, this would immediately raise a host of further questions, including (e.g.) questions for political philosophy, about the proper role for such individuals in a liberal democracy.

explaining reason. See REASONS FOR ACTION, REASONS FOR BELIEF.

explanandum. See EXPLANATION.

explanans. See EXPLANATION.

explanation, an act of making something intelligible or understandable, as when we explain an event by showing why or how it occurred. Just about anything can be the object of explanation: a concept, a rule, the meaning of a word, the point of a chess move, the structure of a novel. However, there are two sorts of things whose explanation has been intensively discussed in philosophy: events and human actions.

Individual events, say the collapse of a bridge, are usually explained by specifying their cause: the bridge collapsed because of the pressure of the floodwater and its weakened structure. This is an example of causal explanation. There usually are indefinitely many causal factors responsible for the occurrence of an event, and the choice of a particular factor as "the cause" appears to depend primarily on contextual considerations. Thus, one explanation of an automobile accident may cite the icy road condition; another the inexperienced driver; and still another the defective brakes. Context may determine which of these and other possible explanations is the appropriate one. These explanations of *why* an event occurred are sometimes contrasted with explanations of *how* an event occurred. A "how" explanation of an event consists in an informative description of the process that led to the occurrence of the event, and such descriptions are likely to involve descriptions of causal processes.

The *covering law model* is an influential attempt to represent the general form of such explanations: an explanation of an event consists in "subsuming," or "covering," it under a law. When the covering law is deterministic, the explanation is thought to take the form of a deductive argument: a statement – the explanandum – describing the event to be explained is logically derived from the explanans – the law together with statements of antecedent conditions. Thus, we might explain why a given rod expanded by offering this argument: 'All metals expand when heated; this rod is metallic and it was heated; therefore, it expanded'. Such an explanation is called a *deductive-nomological explanation*. On the other hand, probabilistic or statistical laws are thought to yield *statistical explanations* of individual events. Thus, the explanation of the contraction of a contagious disease on the basis of exposure to a patient with the disease may take the form of a statistical explanation. Details of the statistical model have been a matter of much controversy. It is sometimes claimed that although explanations, whether in ordinary life or in the sciences, seldom conform fully to the covering law model, the model nevertheless represents an ideal that all explanations must strive to attain. The covering law model, though influential, is not universally accepted.

Human actions are often explained by being "rationalized" – i.e., by citing the agent's beliefs and desires (and other "intentional" mental states such as emotions, hopes, and expectations) that constitute a reason for doing what was done. You opened the window because you wanted some fresh air and believed that by opening the window you could secure this result. It has been a controversial issue whether such rationalizing explanations are causal – i.e., whether they invoke beliefs and desires as a cause of the action. Another issue is whether these "rationalizing" explanations must conform to the covering law model, and if so, what laws might underwrite such explanations.

explosion, a principle of logic according to which an inconsistent set of propositions logically entails any proposition whatsoever. For example, from the contradictory pair of premises that aardvarks are and are not indigenous to Africa, it follows that pigs can fly. (To see this, notice that if aardvarks are indigenous to Africa, then *either* that is so or pigs can fly, and that this, together with the other conjunct of the contradiction, that aardvarks are not indigenous to Africa, entails [via *disjunctive syllogism*] that pigs can fly.)

In classical logic, the validity of explosion flows directly from the definition of logical consequence as necessary truth-preservation in virtue of logical form. However, explosion is not valid in so-called *paraconsistent logics* like relevance logics and dialethic logics.

See also DIALETHEISM, RELEVANCE LOGIC. F.St.

exponible. In medieval logic, exponible propositions were those that needed to be expounded, i.e. elaborated in order to make clear their logical form. A modern example might be 'Giorgione was so called because of his size', which has a misleading form, suggesting a simple predication, whereas it really means 'Giorgione was called "Giorgione" because of his size'. Medieval examples were 'Every man except Socrates is running', expounded as 'Socrates is not running and every man other than Socrates is running'; and 'Only Socrates says something true', uttered by, say, Plato, which Albert of Saxony claims should be expounded not only as 'Socrates says something true and no one other than Socrates says something true', but needs a third clause, 'Plato says something false'.

This last example brings out an important aspect of exponible propositions, namely their use in sophisms. Sophismatic treatises were a common medieval genre in which metaphysical and logical issues were approached dialectically in application to solving puzzle cases. Another important ingredient of exponible propositions was their containing a particular term, sometimes called the exponible term; such terms were a focus of attention in the study of syncategorematic expressions, especially in the thirteenth century. However, note that such exponible terms could be expounded only in context, not by an explicit definition. Syncategorematic terms that produced exponible propositions were terms such as 'twice', 'except', 'begins' and 'ceases', and ‘insofar as’ (e.g. ‘Socrates insofar as he is rational is risible’).

See also SYNCATEGOREMATA. S.L.R.

exportation. (1) In classical logic, the principle that $(A \wedge B) \supset C$ is logically equivalent *to* $A \supset (B \supset C)$. (2) The principle $((A \wedge B) \to C) \to (A \to (B \to C))$, which relevance logicians hold to be fallacious when ‘→’ is read as ‘entails’. (3) In discussions of propositional attitude verbs, the principle that from ‘*a* Vs that *b* is a(n) ϕ’ one may infer ‘*a* Vs ϕ-hood of *b*’, where V has its relational (transparent) sense. For example, exportation (in sense 3) takes one from ‘Ralph believes that Ortcutt is a spy’ to ‘Ralph believes spyhood of Ortcutt’, wherein ‘Ortcutt’ can now be replaced by a bound variable to yield ‘$(\exists x)$ (Ralph believes spyhood of *x*)’. **See also** QUANTIFYING IN, RELEVANCE LOGIC. G.F.S.

expressibility logicism. See LOGICISM.

expressionism. See EXPRESSION THEORY OF ART.

expression theory of art, a theory that defines art as the expression of feelings or emotion (sometimes called “expressionism” in art). Such theories first acquired major importance in the nineteenth century in connection with the rise of Romanticism. Expression theories are as various as the different views about what counts as expressing emotion. There are four main variants.

(1) *Expression as communication*. This requires that the artist actually have the feelings that are expressed, when they are initially expressed. They are “embodied” in some external form, and thereby transmitted to the perceiver. Leo Tolstoy (1828–1910) held a view of this sort.

(2) *Expression as intuition*. An intuition (in this context) is the apprehension of the unity and individuality of something. An intuition is “in the mind,” and hence the artwork is also. Croce held this view, and in his later work argued that the unity of an intuition is established by feeling.

(3) *Expression as clarification*. An artist starts out with vague, undefined feelings, and expression is a process of coming to clarify, articulate, and understand them. This view retains Croce’s idea that expression is in the artist’s mind, as well as his view that we are all artists to the degree that we articulate, clarify, and come to understand our own feelings. Collingwood held this view.

(4) *Expression as a property of the object*. For an artwork to be an expression of emotion is for it to have a given structure or form. Suzanne K. Langer (1895–1985) argued that music and the other arts “presented” or exhibited structures or forms of feeling in general.

expressive completeness. See COMPLETENESS.

expressive meaning. See MEANING.

extension. See INTENSION.

extensionalism, a family of ontologies and semantic theories restricted to existent entities. Extensionalist ontology denies that the domain of any true theory needs to include nonexistents, such as fictional, imaginary, and impossible objects like Pegasus the winged horse or round squares. Extensionalist semantics reduces meaning and truth to set-theoretical relations between terms in a language and the existent objects, standardly spatiotemporal and abstract entities, that belong to the term’s extension. The extension of a name is the particular existent denoted by the name; the extension of a predicate is the set of existent objects that have the property represented by the predicate. The sentence ‘All whales are mammals’ is true in extensionalist semantics provided there are no whales that are not mammals, and no existent objects in the extension of the predicate ‘whale’ that are not also in the extension of ‘mammal’. Linguistic contexts are extensional if (i) they make reference only to existent objects; (ii) they support substitution of co-designative terms (referring to the same thing) or of logically equivalent propositions, *salva veritate* (without loss of truth-value); and (iii) it is logically valid to existentially quantify (conclude that *There exists an object such that* . . ., etc.) objects referred to within the context. Contexts that do not meet these requirements are intensional, non-extensional, or referentially opaque.

The implications of extensionalism, associated with the work of Frege, Russell, Quine, and mainstream analytic philosophy, are to limit its explanations of mind and meaning to existent objects and material-mechanical properties and relations describable in an exclusively extensional idiom. Extensionalist semantics must try to analyze away apparent references to nonexistent objects or, as in Russell’s extensionalist theory of definite descriptions, to classify all such predications as false. Extensionalist ontology in the philosophy of mind must eliminate or reduce propositional attitudes or *de dicto* mental states, expressed in an intensional idiom, such as 'believes that __________', 'fears that __________', and the like, usually in favor of extensional characterizations of neurophysiological states. Whether extensionalist philosophy can satisfy these explanatory obligations, as the thesis of extensionality maintains, is controversial.

externalism, the view that there are objective reasons for action that are not dependent on the agent's desires, and in that sense external to the agent. Internalism (about reasons) is the view that reasons for action must be internal in the sense that they are grounded in motivational facts about the agent, e.g. her desires and goals. Classic internalists such as Hume deny that there are objective reasons for action. For instance, whether the fact that an action would promote health is a reason to do it depends on whether one has a desire to be healthy. It may be a reason for some and not for others. The doctrine is hence a version of relativism; a fact is a reason only insofar as it is so connected to an agent's psychological states that it can motivate the agent. By contrast, externalists hold that not all reasons depend on the internal states of particular agents. Thus an externalist could hold that promoting health is objectively good and that the fact that an action would promote one's health is a reason to perform it regardless of whether one desires health. This dispute is closely tied to the debate over motivational internalism, the view that moral beliefs (for instance) are, by virtue of entailing motivation, internal reasons for action. Those who reject motivational internalism must either deny that (sound) moral beliefs always provide reasons for action or hold that they provide external reasons. **See also** ETHICS, MOTIVATIONAL INTERNALISM, RELATIVISM. extrinsic desire, a desire of something for its conduciveness to something else that one desires. Extrinsic desires are distinguished from *intrinsic* desires, desires of items for their own sake, or as ends. Thus, an individual might desire financial security extrinsically, as a means to her happiness, and desire happiness intrinsically, as an end. Some desires are *mixed:* their objects are desired both for themselves and for their conduciveness to something else. Jacques may desire to jog, e.g., both for its own sake (as an end) and for the sake of his health. A desire is *strictly intrinsic* if and only if its object is desired for itself alone. A desire is *strictly extrinsic* if and only if its object is not desired, even partly, for its own sake. (Desires for "good news" – e.g., a desire to hear that one's child has survived a car accident – are sometimes classified as extrinsic desires, even if the information is desired only because of what it indicates and not for any instrumental value that it may have.)

Desires of each kind help to explain action. Owing partly to a mixed desire to entertain a friend, Martha might acquire a variety of extrinsic desires for actions conducive to that goal. Less happily, intrinsically desiring to be rid of his toothache, George might extrinsically desire to schedule a dental appointment. If all goes well for Martha and George, their desires will be satisfied, and that will be due in part to the effects of the desires upon their behavior.

F

fa, Chinese term for (1) a standard, model, paradigm, or exemplar; (2) proper procedure, behavior, or technique; (3) a rule or law; (4) dharma. A mental image (*yi*) of a circle, a compass, and a particular circle can each serve as a *fa* for identifying circles. The sage-kings, their institutions, and their behavior are all *fa* for rulers to emulate. Methods of governing (e.g., by reward and punishment) are *fa*. Explicit laws or bureaucratic rules are also *fa*. (See *Mozi*, "Dialectical Chapters," and *Guanzi*, Chapter 6, "Seven Standards.") Since the introduction of Buddhism to China, *fa* has been used to translate 'dharma'. **See also** **BUDDHISM, DHARMA, MOZI.** B.W.V.N.

fact. See STATE OF AFFAIRS, TRUTHMAKER.

facticity. See HEIDEGGER, SARTRE.

factual content. See ANALYTIC-SYNTHETIC DISTINCTION.

fact-value distinction, the apparently fundamental difference between how things are and how they should be. That people obey the law (or act honestly or desire money) is one thing; that they should is quite another. The first is a matter of fact, the second a matter of value. Hume is usually credited with drawing the distinction when he noticed that one cannot uncontroversially infer an 'ought' from an 'is' (the is-ought gap). From the fact, say, that an action would maximize overall happiness, we cannot legitimately infer that it ought to be done – without the introduction of some (so far suppressed) evaluative premise. We could secure the inference by assuming that one ought always to do what maximizes overall happiness. But that assumption is evaluative. And any other premise that might link the non-evaluative premises to an evaluative conclusion would look equally evaluative. No matter how detailed and extensive the non-evaluative premises, it seems no evaluative conclusion follows (directly and as a matter of logic). Some have replied that at least a few non-evaluative claims do entail evaluative ones. To take one popular example, from the fact that some promise was made, we might (it appears) legitimately infer that it ought to be kept, other things equal – and this without the introduction of an evaluative premise. Yet many argue that the inference fails, or that the premise is actually evaluative, or that the conclusion is not.

Hume himself was both bold and brief about the gap's significance, claiming simply that paying attention to it "wou'd subvert all the vulgar systems of morality, and let us see, that the distinction of vice and virtue is not founded merely on the relations of objects, nor is perceiv'd by reason" (*Treatise of Human Nature*). Others have been more expansive. Moore, for instance, in effect relied upon the gap to establish (via the open question argument) that any attempt to define evaluative terms using non-evaluative ones would commit the naturalistic fallacy. Moore's main target was the suggestion that 'good' *means* 'pleasant' and the fallacy, in this context, is supposed to be misidentifying an evaluative property, being good, with a natural property, being pleasant. Assuming that evaluative terms have meaning, Moore held that some could be defined using others (he thought, e.g., that 'right' could be defined as 'productive of the greatest possible good') and that the rest, though meaningful, must be indefinable terms denoting simple, non-natural properties. Accepting Moore's use of the open question argument but rejecting both his non-naturalism and his assumption that evaluative terms must have (descriptive) meaning, emotivists and prescriptivists (e.g., Ayer, Stevenson, and Hare) argued that evaluative terms have a role in language other than to denote properties. For them, the primary role of evaluative language is not to describe, but to prescribe. The logical gap between 'is' and 'ought', they argue, establishes both the difference between fact and value and the difference between describing (how things are) and recommending (how they should be). Some naturalists, though, acknowledge the gap and yet maintain that the evaluative claims nonetheless do refer to natural properties. Thus they deny the ontological force of the open question argument and treat evaluative claims as describing a special class of facts.

faculty psychology, the view that the mind is a collection of departments responsible for distinct psychological functions. Related to faculty psychology is the doctrine of localization of function, wherein each faculty has a specific brain location. Faculty psychologies oppose theories of mind as a unity with one function (e.g., those of Descartes and associationism) or as a unity with various capabilities (e.g., that of Ockham), and oppose the related holistic distributionist or mass-action theory of the brain. Faculty psychology began with Aristotle, who divided the human soul into five *special senses*, three *inner senses* (common sense, imagination, memory), and *active* and *passive mind*. In the Middle Ages (e.g., Aquinas), Aristotle's three inner senses were subdivided, creating more elaborate lists of five to seven *inward wits*. Islamic physician-philosophers such as Avicenna integrated Aristotelian faculty psychology with Galenic medicine by proposing brain locations for the faculties.

Two important developments in faculty psychology occurred during the eighteenth century. First, Scottish philosophers led by Reid developed a version of faculty psychology opposed to the empiricist and associationist psychologies of Locke and Hume. The Scots proposed that humans were endowed by God with a set of faculties permitting knowledge of the world and morality. The Scottish system exerted considerable influence in the United States, where it was widely taught as a moral, character-building discipline, and in the nineteenth century this "Old Psychology" opposed the experimental "New Psychology." Second, despite then being called a charlatan, Franz Joseph Gall (1758–1828) laid the foundation for modern neuropsychology in his work on localization of function. Gall rejected existing faculty psychologies as philosophical, unbiological, and incapable of accounting for everyday behavior. Gall proposed an innovative behavioral and biological list of faculties and brain localizations based on comparative anatomy, behavior study, and measurements of the human skull. Today, faculty psychology survives in trait and instinct theories of personality, Fodor's theory that mental functions are implemented by neurologically "encapsulated" organs, and localizationist theories of the brain.

faith, a psychological attitude commonly expressed by either of two locutions: 'faith *that*', e.g. 'Shelly has faith that her sons will flourish'; and 'faith *in*', e.g. 'Mallory has faith in his new ice ax'. Faith *in* is always relative to some things and not others; e.g., 'Mallory has faith in his ice ax as a rescue tool, not as a kitchen implement'. To have faith in *x* is to entrust one's well-being to *x* in some way. One can have faith *that* without faith *in*, as when I have faith that Emily will survive breast cancer, but I do not entrust my well-being to her survival. Nor should we identify faith *that* with hope *that*. Lost at dusk in the North Cascades, you might hope for rescue, but faith requires a more positive cognitive stance than hope. Moreover, I can have faith that the mechanic will fix the 1,200cc engine of my beloved 1963 Volkswagen Bug, but I cannot hope that he will fix it, since I am certain he will succeed; hope requires a less positive cognitive stance than that. Faith that *p* requires caring (with positive valence) that *p*, although such care may be weak and conflicted. Faith that *p* further requires resilience in the face of contrary evidence, as well as being prepared to act as if *p* is true. But, as argued by Audi and others, faith that *p* does not require belief that *p;* other items can stand in for the positive cognitive stance faith requires, e.g. acceptance of *p*, assent to *p*, trust that *p*, and non-doxastically assuming that *p*. Since each of these items is compatible with having doubts about whether *p* and since some are even compatible with being *in* doubt about whether *p*, faith is compatible with doubt. Indifference and hostility, not doubt, are the enemies of faith.

When someone is described as a "person of faith" what is usually intended is a "person having religious faith" – e.g., faith in God and associated instances of faith *that*, say faith that God loves human beings. A different notion is designated by the expression 'a faith' or 'the faith', as in St. Jude's admonition to Christians to "earnestly contend for the faith"; in this case, it is used for something non-psychological: a connected set of tenets such that holding them (especially as objects of propositional faith) implies being *of* that faith.

fallibilism, the doctrine, relative to some significant class of beliefs or propositions, that they are inherently uncertain and possibly mistaken. The most extreme form of the doctrine attributes uncertainty to every belief; more restricted forms attribute it to all empirical beliefs or to beliefs concerning the past, the future, other minds, or the external world. Most contemporary philosophers reject the doctrine in its extreme form, holding that beliefs about such things as elementary logical principles and the character of one's current feelings cannot possibly be mistaken. Philosophers who reject fallibilism in some form generally insist that certain beliefs are analytically true, self-evident, or intuitively obvious. These means of supporting the infallibility of some beliefs are now generally discredited. Quine has cast serious doubt on the very notion of analytic truth, and the appeal to self-evidence or intuitive obviousness is open to the charge that those who officially accept it do not always agree on what is thus evident or obvious (there is no objective way of identifying it), and that beliefs said to be self-evident have sometimes been proved false, the causal principle and the axiom of abstraction (in set theory) being striking examples. In addition to emphasizing the evolution of logical and mathematical principles, fallibilists have supported their position mainly by arguing that the existence and nature of mind-independent objects can legitimately be ascertained only be experimental methods and that such methods can yield conclusions that are, at best, probable rather than certain. B.A.

false cause, fallacy of. See INFORMAL FALLACY.

false consciousness, (1) lack of clear awareness of the source and significance of one's beliefs and attitudes concerning society, religion, or values; (2) objectionable forms of ignorance and false belief; (3) dishonest forms of self-deception. Marxists (if not Marx) use the expression to explain and condemn illusions generated by unfair economic relationships. Thus, workers who are unaware of their alienation, and "happy homemakers" who only dimly sense their dependency and quiet desperation, are molded in their attitudes by economic power relationships that make the status quo seem natural, thereby eclipsing their long-term best interests. Again, religion is construed as an economically driven ideology that functions as an "opiate" blocking clear awareness of human needs. Collingwood interprets false consciousness as self-corrupting untruthfulness in disowning one's emotions and ideas (*The Principles of Art*, 1938). **See also** **BAD FAITH, EXISTENTIALISM.** M.W.M.

false dilemma. See DILEMMA.

false pleasure, pleasure taken in something false. If it is false that Jones is honest, but Smith believes Jones is honest and is pleased that Jones is honest, then Smith's pleasure is false. If pleasure is construed as an intentional attitude, then the truth or falsity of a pleasure is a function of whether its intentional object obtains. On this view, S's being pleased that p is a true pleasure if and only if S is pleased that p and p is true. S's being pleased that p is a false pleasure if and only if S is pleased that p and p is false. Alternatively, Plato uses the expression 'false pleasure' to refer to things such as the cessation of pain or to neutral states that are neither pleasant nor painful but are confused by the subject with genuine or true pleasures. Thus, being released from tight shackles might mistakenly be thought pleasant when it is merely the cessation of a pain. **See also** **HEDONISM, VALUE.** N.M.L.

Fechner, Gustav Theodor (1801–87), German physicist and philosopher whose *Elemente der Psychophysik* (1860; English translation, 1966) inaugurated experimental psychology. Obsessed with the mind-body problem, Fechner advanced an identity theory in which every object is both mental and physical, and in support invented psychophysics – the "exact science of the functional relations . . . between mind and body." Fechner began with the concept of the *limen*, or sensory threshold. The *absolute threshold* is the stimulus strength (R, *Reiz*) needed to create a conscious sensation (S), and the *relative threshold* is the strength that must be added to a stimulus for a *just noticeable difference* (jnd) to be perceived. E. H. Weber (1795–1878) had shown that a constant ratio held between relative threshold and stimulus magnitude, Weber's law: $\Delta R/R = k$. By experimentally determining jnd's for pairs of stimulus magnitudes (such as weights), Fechner formulated his "functional relation," $S = k \log R$, Fechner's law, an identity equation of mind and matter. Later psychophysicists replaced it with a power law, $R = kS^n$, where n depends on the kind of stimulus. The importance of psychophysics to psychology consisted in its showing that quantification of experience was possible, and its providing a general paradigm for psychological experimentation in which controlled stimulus conditions are systematically varied and effects observed. In his later years, Fechner brought the experimental method to bear on aesthetics (*Vorschule der Aesthetik*, 1876). T.H.L.

feminist epistemology, epistemology from a feminist perspective. It investigates the relevance that the gender of the inquirer/knower has to epistemic practices, including the theoretical practice of epistemology. It is typified both by themes that are exclusively feminist in that they could arise only from a critical attention to gender, and by themes that are non-exclusively feminist in that they might arise from other politicizing theoretical perspectives besides gender, such as race or class.

In the development of feminist epistemology, a central, exclusively feminist theme has been the relation between philosophical conceptions of reason and cultural conceptions of masculinity. Here a historicist stance must be adopted, so that philosophy is conceived as the product of historically and culturally situated (hence gendered) authors. This stance brings certain patterns of intellectual association into view – patterns, perhaps, of alignment between philosophical conceptions of reason as contrasted with emotion or intuition, and cultural conceptions of masculinity as contrasted with femininity.

A central, non-exclusively feminist theme has been the socialization of epistemology. Historically it has two main tributaries: political philosophy, in the form of Marx's historical materialism; and philosophy of science, in the form of either Quinean naturalism or Kuhnian historicism. The first inspired feminist standpoint theory, which adapts and develops the originally Marxian idea that different social groups have different epistemic standpoints, where the material positioning of one of the groups is said to bestow an epistemic privilege. The second has resulted in feminist work in philosophy of science which tries to show that not only epistemic values but also non-epistemic (e.g., gendered) values are of necessity sometimes an influence in the generation of scientific theories. If this can be shown, then an important feminist project suggests itself: to work out a rationale for regulating the influence of these values so that science may be more self-transparent and more responsible.

The rise of virtue epistemology and social epistemology more generally have created new overlaps between feminist concerns and questions in epistemology about the contingent aspects of our epistemic practices, and in particular the practical, ethical, and political aspects of how inquiry is conducted and knowledge generated or indeed suppressed.

By attempting to reveal the epistemological implications of the fact that knowers are diversely situated in social relations of identity and power, feminist epistemology represents a radicalizing innovation in the analytic tradition, which has typically assumed an asocial conception of the epistemic subject and of the philosopher.

M.F.

feminist philosophy, a discussion of philosophical concerns that refuses to identify the human experience with the male experience. Writing from a variety of perspectives, feminist philosophers challenge several areas of traditional philosophy on the grounds that they fail (1) to take seriously women's interests, identities, and issues; and (2) to recognize women's ways of being, thinking, and doing as valuable as those of men.

Feminist philosophers fault traditional metaphysics for splitting the self from the other and the mind from the body; for wondering whether "other minds" exist and whether personal identity depends more on memories or on physical characteristics. Because feminist philosophers reject all forms of ontological dualism, they stress the ways in which individuals interpenetrate each other's psyches through empathy, and the ways in which the mind and body co-constitute each other.

Because Western culture has associated rationality with "masculinity" and emotionality with "femininity," traditional epistemologists have often concluded that women are less human than men. For this reason, feminist philosophers argue that reason and emotion are symbiotically related, coequal sources of knowledge. Feminist philosophers also argue that Cartesian knowledge, for all its certainty and clarity, is very limited. People want to know more than that they exist; they want to know what other people are thinking and feeling.

Feminist philosophers also observe that traditional philosophy of science is not as objective as it claims to be. Whereas traditional philosophers of science often associate scientific success with scientists' ability to control, rule, and otherwise dominate nature, feminist philosophers of science associate scientific success with scientists' ability to listen to nature's self-revelations. Since it willingly yields abstract theory to the testimony of concrete fact, a science that listens to what nature says is probably more objective than one that does not.

Feminist philosophers also criticize traditional ethics and traditional social and political philosophy. Rules and principles have dominated much of traditional ethics. Whether agents seek to maximize utility for the aggregate or do their duty for the sake of duty, they measure their conduct against a set of universal, abstract, and impersonal norms. Feminist ethicists often call this traditional view of ethics a "justice" perspective, contrasting it with a "care" perspective that stresses responsibilities and relationships rather than rights and rules, and that attends more to a moral situation's particular features than to its general implications.

Feminist social and political philosophy focuses on the political institutions and social practices that perpetuate women's subordination. The goals of feminist social and political philosophy are varied and historically changing. However, the following might be indicative: (1) to explain why women are suppressed, repressed, and/or oppressed in ways that men are not; and (2) to suggest morally desirable and politically feasible ways to give women the same justice, freedom, and equality that men have. There are, as ever, feminist theorists of different stripes. Liberal feminists believe that because women have the same rights as men do, society must provide women with the same educational and occupational opportunities that men have. Marxist feminists believe that women cannot be men's equals until women enter the workforce en masse and domestic work and child care are socialized. Radical feminists believe that the fundamental causes of women's oppression are sexual. It is women's reproductive role and/or their sexual role that causes their subordination. Unless women set their own reproductive goals (childlessness is a legitimate alternative to motherhood) and their own sexual agendas (lesbianism, autoeroticism, and celibacy are alternatives to heterosexuality), women will remain less than free. Psychoanalytic feminists believe that women's subordination is the result of early childhood experiences that cause them to overdevelop their abilities to relate to other people, on the one hand, and to underdevelop their abilities to assert themselves as autonomous agents, on the other. Women's greatest strength, a capacity for deep relationships, may also be their greatest weakness: a tendency to be controlled by the needs and wants of others. Finally, existentialist feminists claim that the ultimate cause of women's subordination is ontological. Women are the Other; men are the Self. Until women define themselves in terms of themselves, they will continue to be defined in terms of what they are not: men.

Socialist feminists have attempted to weave these distinctive strands of feminist social and political thought into a theoretical whole. They argue that women's condition is overdetermined by the structures of production, reproduction, and sexuality and the socialization of children. Women's status and function in *all* of these structures must change if they are to achieve full liberation. Furthermore, women's psyches must also be transformed. Only then will women be liberated from the kind of patriarchal thoughts that undermine their self-concept and make them always the Other.

Interestingly, the socialist feminist effort to establish a specifically feminist standpoint that represents how women see the world has not gone without challenge. Postmodern feminists regard this effort as an instantiation of the kind of typically male thinking that tells only one story about reality, truth, knowledge, ethics, and politics. For postmodern feminists, such a story is neither feasible nor desirable. It is not feasible because women's experiences differ across class, racial, and cultural lines. It is not desirable because the "One" and the "True" are philosophical myths that traditional philosophy uses to silence the voices of the many. Feminist philosophy must be many and not One because women are many and not One. The more feminist thoughts, the better. By refusing to center, congeal, and cement separate thoughts into a unified and inflexible truth, feminist philosophers can avoid the pitfalls of traditional philosophy.

As attractive as the postmodern feminist approach to philosophy may have been to some, other feminist philosophers raised concerns that an overemphasis on difference and a rejection of unity would lead to intellectual as well as political disintegration. If feminist philosophy is to be without any standpoint whatsoever, it becomes difficult to ground claims about what is *good* for women in particular and for human beings in general. It is a major challenge to contemporary feminist philosophy, therefore, to reconcile the pressures for diversity and difference with those for integration and commonality.

Feng Youlan (Fung Yu-lan) (1895–1990), Chinese philosopher. He was educated at Peking University and earned his Ph.D. from Columbia University. His *History of Chinese Philosophy* was the first such complete history of high quality by a contemporary scholar. During World War II he attempted to reconstruct Zhu Xi's philosophy in terms of the New Realism that he had learned from the West, and developed his own system of thought, a new philosophy of *li* (principle). After the Communist takeover in 1949, he gave up his earlier thought, denouncing Confucian philosophy during the Cultural Revolution. After the Cultural Revolution he changed his position again and rewrote his *History of Chinese Philosophy* in seven volumes. **See also** CHINESE PHILOSOPHY, ZHU XI. S.-h.L.

Ferguson, Adam (1723–1816), Scottish philosopher and historian whose main theme was the rise and fall of virtue in individuals and societies. In his most important work, *An Essay on the History of Civil Society* (1766), he argued that human happiness (of which virtue is a constituent) is found in pursuing social goods rather than private ends. Ferguson thought that ignoring social goods not only prevented social progress but led to moral corruption and political despotism. To support this he used classical texts and travelers' writings to reconstruct the history of society from "rude-nations" through barbarism to civilization. This allowed him to express his concern for the danger of corruption inherent in the increasing self-interest manifested in the incipient commercial civilization of his day. He attempted to systematize his moral philosophy in *The Principles of Moral and Social Science* (1792). J.W.A.

Fermat's last theorem. See CHOICE SEQUENCE.

Feuerbach, Ludwig Andreas (1804–72), German materialist philosopher and critic of religion who provided the major link between Hegel's absolute idealism and such later theories of historical materialism as those of Marx and other "young (or new) Hegelians." Feuerbach was born in Bavaria and studied theology, first at Heidelberg and then Berlin, where he came under the philosophical influence of Hegel. He received his doctorate in 1828 and, after an early publication severely critical of Christianity, retired from official German academic life. In the years between 1836 and 1846, he produced some of his most influential works, which include "Towards a Critique of Hegel's Philosophy" (1839), *The Essence of Christianity* (1841), *Principles of the Philosophy of the Future* (1843), and *The Essence of Religion* (1846). After a brief collaboration with Marx, he emerged as a popular champion of political liberalism in the revolutionary period of 1848. During the reaction that followed, he again left public life and died dependent upon the support of friends.

Feuerbach was pivotal in the intellectual history of the nineteenth century in several respects. First, after a half-century of metaphysical system construction by the German idealists, Feuerbach revived, in a new form, the original Kantian project of philosophical critique. However, whereas Kant had tried "to limit reason in order to make room for faith," Feuerbach sought to demystify both faith and reason in favor of the concrete and situated existence of embodied human consciousness. Second, his "method" of "transformatory criticism" – directed, in the first instance, at Hegel's philosophical pronouncements – was adopted by Marx and has retained its philosophical appeal. Briefly, it suggested that "Hegel be stood on his feet" by "inverting" the subject and predicate in Hegel's idealistic pronouncements. One should, e.g., rewrite "The individual is a function of the Absolute" as "The Absolute is a function of the individual." Third, Feuerbach asserted that the philosophy of German idealism was ultimately an extenuation of theology, and that theology was merely religious consciousness systematized. But since religion itself proves to be merely a "dream of the human mind," metaphysics, theology, and religion can be reduced to "anthropology," the study of concrete embodied human consciousness and its cultural products.

The philosophical influence of Feuerbach flows through Marx into virtually all later historical materialist positions; anticipates the existentialist concern with concrete embodied human existence; and serves as a paradigm for all later approaches to religion on the part of the social sciences.

J.P.Su.

Fichte, Johann Gottlieb (1762–1814), German philosopher who was a proponent of an uncompromising system of transcendental idealism, the *Wissenschaftslehre*, which played a key role in the development of post-Kantian philosophy. Born in Saxony, Fichte studied at Jena and Leipzig. The writings of Kant led him to abandon metaphysical determinism and to embrace transcendental idealism as "the first system of human freedom." His first book, *Versuch einer Kritik aller Offenbarung* ("Attempt at a Critique of All Revelations," 1792), earned him a reputation as a brilliant exponent of Kantianism, while his early political writings secured him a reputation as a Jacobin. Inspired by Reinhold, Jacobi, Maimon, and Schulze, Fichte rejected the "letter" of Kantianism and, in the lectures and writings he produced at Jena (1794–99), advanced a new, rigorously systematic presentation of what he took to be its "spirit." He dispensed with Kant's things-in-themselves, the original duality of faculties, and the distinction between the transcendental aesthetic and the transcendental analytic. By emphasizing the unity of theoretical and practical reason in a way consistent with "the primacy of practical reason," Fichte sought to establish the unity of the critical philosophy as well as of human experience.

In *Ueber den Begriff der Wissenschaftslehre* ("On the Concept of the *Wissenschaftslehre*," 1794) he explained his conception of philosophy as "the science of science," to be presented in a deductive system based on a self-evident first principle. The basic "foundations" of this system, which Fichte called *Wissenschaftslehre* (theory of science), were outlined in his *Grundlage der gesamten Wissenschaftslehre* ("Foundations of the Entire *Wissenschaftslehre*," 1794–95) and *Grundriß der Eigentümlichen der Wissenschaftslehre in Rücksicht auf das theoretische Vermögen* ("Outline of the Distinctive Character of the *Wissenschaftslehre* with Respect to the Theoretical Faculty," 1795) and then, substantially revised, in his lectures *Wissenschaftslehre nova methodo* (1796–99).

The "foundational" portion of the *Wissenschaftslehre* links our affirmation of freedom to our experience of natural necessity. Beginning with the former ("the I simply posits itself"), it then demonstrates how a freely self-positing subject must be conscious not only of itself, but also of "representations accompanied by a feeling of necessity" and hence of an objective world. Fichte insisted that the essence of selfhood lies in an active positing of its own self-identity and hence that self-consciousness is an autoproductive *activity:* a *Tathandlung*, or 'fact/act'. However, the I can posit itself only as *limited;* in order for the originally posited act of "sheer self-positing" to occur, certain other mental acts must occur as well, acts through which the I posits for itself an objective, spatiotemporal world, as well as a moral realm of free, rational beings. The I first posits its own limited condition in the form of "feeling" (occasioned by an inexplicable *Anstob*, or 'check', upon its own practical striving), then as a "sensation," then as an "intuition" of a thing, and finally as a "concept." The distinction between the I and the not-I arises only in these reiterated acts of self-positing, a complete description of which thus amounts to a "genetic deduction" of the necessary conditions of experience. Freedom is thereby shown to be possible only in the context of natural necessity, where it is limited and finite. At the same time "our freedom is a theoretical determining principle of our world." Though it must posit its freedom "absolutely" – i.e., *schlechthin*, or 'for no reason' – a genuinely free agent can exist only as a finite individual endlessly striving to overcome its own limits.

After establishing its "foundations," Fichte extended his *Wissenschaftslehre* into social and political philosophy and ethics. Subjectivity itself is essentially *intersubjective*, inasmuch as one can be empirically conscious of oneself only as one *individual* among many and must thus posit the freedom of others in order to posit one's own freedom. But for this to occur, the freedom of each individual must be limited; indeed, "the concept of right or justice (*Recht*) is nothing other than the concept of the coexistence of the freedom of several rational/sensuous beings." The *Grundlage des Naturrechts* ("Foundations of Natural Right," 1796–97) examines how individual freedom must be externally limited if a community of free individuals is to be possible, and demonstrates that a just political order is a demand of reason itself, since "the concept of justice or right is a condition of self-consciousness." "Natural rights" are thus entirely independent of moral duties. Unlike political philosophy, which purely concerns the public realm, ethics, which is the subject of *Das System der Sittenlehre* ("The System of Ethical Theory," 1798), concerns the inner realm of conscience. It views objects not *as given* to consciousness but as *produced* by free action, and concerns not what *is*, but what *ought* to be. The task of ethics is to indicate the particular duties that follow from the general obligation to determine oneself freely (the categorical imperative).

Before Fichte could extend the *Wissenschaftslehre* into the philosophy of religion, he was accused of atheism and forced to leave Jena. The celebrated controversy over his alleged atheism (the *Atheismusstreit*) was provoked by his "Ueber den Grund unseres Glaubens in einer göttliche Wel-tregierung" ("On the Basis of Our Belief in a Divine Governance of the World," 1798), which sharply distinguished philosophical from religious questions. While defending our right to posit a "moral world order," Fichte insisted that this order does not require a personal deity or "moral lawgiver."

After moving to Berlin, Fichte's first concern was to rebut the charge of atheism and to reply to the indictment of philosophy as "nihilism" advanced in Jacobi's *Open Letter to Fichte* (1799). This was the task of *Die Bestimmung des Menschen* ("The Vocation of Man," 1800). During the French occupation, he delivered *Reden an die deutsche Nation* ("Addresses to the German Nation," 1808), which proposed a program of national education and attempted to kindle German patriotism. The other publications of his Berlin years include a foray into political economy, *Der geschlossene Handelstaat* ("The Closed Commercial State," 1800); a speculative interpretation of human history, *Die Grundzüge des gegenwärtiges Zeitalters* ("The Characteristics of the Present Age," 1806); and a mystically tinged treatise on salvation, *Die Anweisung zum seligen Leben* ("Guide to the Blessed Life," 1806). In unpublished private lectures he continued to develop radically new versions of the *Wissenschaftslehre*.

Fichte's importance is not limited to his well-known influence on Schelling and Hegel (both of whom criticized the "subjectivism" of the early *Wissenschaftslehre*). He is also important in the history of German nationalism and profoundly influenced the early Romantics, especially Novalis and Schlegel. Recent decades have seen renewed interest in Fichte's transcendental philosophy, especially the later, unpublished versions of the *Wissenschaftslehre*. The twentieth century's most significant contribution to Fichte studies, however, is the ongoing publication of the first critical edition of his complete works.

Ficino, Marsilio (1433–99), Italian Neoplatonic philosopher who played a leading role in the cultural life of Florence. Ordained a priest in 1473, he hoped to draw people to Christ by means of Platonism. It was through Ficino's translation and commentaries that the works of Plato first became accessible to the Latin-speaking West, but the impact of Plato's work was considerably affected by Ficino's other interests. He accepted Neoplatonic interpretations of Plato, including those of Plotinus, whom he translated; and he saw Plato as the heir of Hermes Trismegistus, a mythical Egyptian sage and supposed author of the Hermetic Corpus, which he translated early in his career. He embraced the notion of a *prisca theologia*, an ancient wisdom that encapsulated philosophic and religious truth, was handed on to Plato, and was later validated by the Christian revelation. The most popular of his original works was *Three Books on Life* (1489), which contains the fullest Renaissance exposition of a theory of magic, based mainly on Neoplatonic sources. He postulated a living cosmos in which the World-Soul is linked to the world-body by spirit. This relationship is mirrored in man, whose spirit (or astral body) links his body and soul, and the resulting correspondence between microcosm and macrocosm allows both man's control of natural objects through magic and his ascent to knowledge of God. Other popular works were his commentary on Plato's *Symposium* (1469), which presents a theory of Platonic love; and his *Platonic Theology* (1474), in which he argues for the immortality of the soul. **See also** NEOPLATONISM. E.J.A.

fiction, in the widest usage, whatever contrasts with what is a matter of fact. As applied to works of fiction, however, this is not the appropriate contrast. For a work of fiction, such as a historical novel, might turn out to be true regarding its historical subject, without ceasing to be fiction. The correct contrast of fiction is to non-fiction. If a work of fiction might turn out to be true, how is 'fiction' best defined? According to some philosophers, such as Searle, the writer of non-fiction performs illocutionary speech acts, such as asserting that such-and-such occurred, whereas the writer of fiction characteristically only *pretends* to perform these illocutionary acts. Others hold that the core idea to which appeal should be made is that of making-believe or imagining certain states of affairs. Kendall Walton (*Mimesis as Make-Believe*, 1990), for instance, holds that a work of fiction is to be construed in terms of a prop whose function is to serve in games of make-believe. Both kinds of theory allow for the possibility that a work of fiction might turn out to be true. **See also** AESTHETICS, IMAGINATION, PHILOSOPHY OF LITERATURE, SPEECH ACT THEORY. B.Ga.

fiction, logical. See LOGICAL CONSTRUCTION.

fictionalism, the view that the usefulness and/or acceptability of statements made within a domain of discourse can be explained by treating them as (or as importantly similar to) fictional statements. For example, one who repudiates the real existence of numbers might hold that 'The number of my fingers is equal to the number of my toes' can be useful because it conveys, by way of a number-fiction, that the speaker's fingers can be paired exactly with the speaker's toes. Likewise, one who repudiates the real existence of tables might hold that 'There is a table here' can be useful because it conveys, by way of a furniture-fiction, that there are some simples arranged tablewise here. (Fictionalism has been applied to various other kinds of language, including ethical and modal language.)

It is uncontroversial that statements made within a fiction can get across truths about the real world. (Suppose, e.g., that there is an eerie screech outside on windy nights, and we establish a fiction according to which it is caused by a ghost. A claim within the fiction like 'The ghost kept me up twice this week' will then convey a claim about the real world.) But fictionalisms differ about whether speakers actually *assert* truths with the target statements, or only falsehoods. They also differ about whether the target statements are *in fact* fictional in any sense. According to a revisionary brand of fictionalism, this may be ruled out by the lack of any intent by speakers to engage in a pretense; still, the usefulness/acceptability of the target statements can be salvaged by replacing them in one's official theory with statements about what is the case according to a fiction about (for example) numbers.

fideism. See EVIDENTIALISM.

"Fido"-Fido theory of meaning. See MEANING.

field (of a relation). See RELATION.

field theory, a theory that proceeds by assigning values of physical quantities to the points of space, or of space-time, and then lays down laws relating these values. For example, a field theory might suppose a value for matter density, or a temperature for each space-time point, and then relate these values, usually in terms of differential equations. In these examples there is at least the tacit assumption of a physical substance that fills the relevant region of space-time. But no such assumption need be made. For instance, in Maxwell's theory of the electromagnetic field, each point of space-time carries a value for an electric and a magnetic field, and these values are then governed by Maxwell's equations. In general relativity, the geometry (e.g., the curvature) of space-time is itself treated as a field, with lawlike connections with the distribution of energy and matter.

Formulation in terms of a field theory resolves the problem of action at a distance that so exercised Newton and his contemporaries. We often take causal connection to require spatial contiguity. That is, for one entity to act causally on another, the two entities need to be contiguous. But in Newton's description gravitational attraction acts across spatial distances. Similarly, in electrostatics the mutual repulsion of electric charges is described as acting across spatial distances. In the times of both Newton and Maxwell numerous efforts to understand such action at a distance in terms of some space-filling mediating substance produced no viable theory. Field theories resolve the perplexity. By attributing values of physical quantities directly to the space-time points one can describe gravitation, electrical and magnetic forces, and other interactions without action at a distance or any intervening physical medium. One describes the values of physical quantities, attributed directly to the space-time points, as influencing only the values at immediately neighboring points. In this way the influences propagate through space-time, rather than act instantaneously across distances or through a medium. Of course, there is a metaphysical price: on such a description the space-time points themselves take on the role of a kind of dematerialized ether. Indeed, some have argued that the pervasive role of field theory in contemporary physics and the need for space-time points for a field-theoretic description constitute a strong argument for the existence of the space-time points. This conclusion contradicts "relationalism," which claims that there are only spatiotemporal relations, but no space-time points or regions thought of as particulars.

Quantum field theory appears to take on a particularly abstract form of field theory, since it associates a quantum mechanical operator with each space-time point. However, since operators correspond to physical magnitudes rather than to values of such magnitudes, it is better to think of the field-theoretic aspect of quantum field theory in terms of the quantum mechanical amplitudes that it also associates with the space-time points.

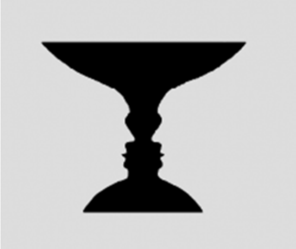
P.Te.

figure. See SYLLOGISM.

figure-ground, the discrimination of an object or figure from the context or background against which it is set. Even when a connected region is grouped together properly, as in the famous figure that can be seen either as a pair of faces or as a vase, it is possible to interpret the region alternately as figure and as ground. This fact was originally elaborated in 1921 by Edgar Rubin (1886–1951). Figure-ground effects and the existence of other ambiguous figures such as the Necker cube and the duck-rabbit challenged the prevailing assumption in classical theories of perception-maintained, e.g. by J. S. Mill and Helmholtz, that complex perceptions could be understood in terms of primitive sensations constituting them.

The underdetermination of perception by the visual stimulus, noted by Berkeley in his *Essay* of 1709, takes account of the fact that the retinal image is impoverished with respect to three-dimensional information. Identical stimulation at the retina can result from radically different distal sources. Within Gestalt psychology, the *Gestalt*, or pattern, was recognized to be underdetermined by constituent parts available in proximal stimuli. M. Wertheimer (1880–1943) observed in 1912 that apparent motion could be induced by viewing a series of still pictures in rapid succession. He concluded that perception of the whole, as involving movement, was fundamentally different from the perception of the static images of which it is composed. W. Köhler (1887–1967) observed that there was no figure-ground articulation in the retinal image, and concluded that inherently ambiguous stimuli required some autonomous selective principles of perceptual organization. As later developed by Gestalt psychologists, form is taken as the primitive unit of perception. In philosophical treatments, figure-ground effects are used to enforce the conclusion that interpretation is central to perception, and that perceptions are no more than hypotheses based on sensory data.



See also DUCK-RABBIT, KÖHLER, PERCEPTION.

R.C.R.

film, philosophy of. See PHILOSOPHY OF FILM.

Filmer, Robert (1588–1653), English political writer whose important posthumous *Patriarcha* (1680) is remembered because Locke attacked it in the first of his *Two Treatises of Government* (1690). Filmer argued that God gave complete authority over the world to Adam, and that from him it descended to his eldest son when he became the head of the family. Thereafter only fathers directly descended from Adam could properly rule. Just as Adam's rule was not derived from the consent of his family, so the king's inherited authority does not depend on popular consent. He rightly makes laws and imposes taxes at his own good pleasure, though like a good father he has the welfare of his subjects in view. Filmer's patriarchalism, intended to bolster the absolute power of the king, is the classic English statement of the doctrine. **See also** POLITICAL PHILOSOPHY. J.B.S.

final cause. See ARISTOTLE.

Fine, Kit (b.1946), Anglo-American philosopher who has made seminal contributions to philosophy of language, metaphysics, and philosophy of mathematics, and to topics in philosophical logic, such as modal and relevance logics and the logics of essence and of vagueness. He was educated at Balliol College and the University of Warwick (Ph.D., 1969) and currently is University Professor and Silver Professor of Philosophy and Mathematics at NYU.

In the 1970s, much of his work was in mathematical logic, and his major results in the metamathematics of modal logic included fundamental contributions (*An Incomplete Logic Containing S4*, 1974; *Failures of the Interpolation Lemma in Quantified Modal Logic*, 1979). He then investigated modal logic, including the *de re/de dicto* distinction, formal properties of essentialist theories, modal set theory, and the reduction of possibilist to actualist discourse (*Model Theory for Modal Logic*, in three parts, 1978, 1981; *Worlds, Times, and Selves*, with A. N. Prior, 1977).

Eventually, Fine became dissatisfied with the standard modal account of individual essence. He argued that the modal account is not sufficiently fine-grained; for the mere necessity of Socrates' belonging to the singleton Socrates, if he exists, does not make belonging to his own singleton part of his essence. Fine resuscitated a more Aristotelian account, maintaining that realist definitions rather than *de re* modalities better account for essence (*Essence and Modality*, 1994; *The Logic of Essence*, 1995).

Fine also contributed to the philosophy of vagueness, where he was one of the developers of supervaluationism (*Vagueness, Truth, and Logic*, 1975); philosophy of logic, where he justified the approach to reasoning with existentials according to which instances may *follow* from existentials so long as those instances refer to arbitrary objects (*Reasoning with Arbitrary Objects*, 1986); philosophy of mathematics, where he developed a new theory of abstraction and postulation (*The Limits of Abstraction*, 1998, 2002); and philosophy of language, in which he made a breakthrough with his conception of semantic relationism (*Semantic Relationism*, 2007).

Fine has recently been developing his views on essence and ground, realism, and material constitution (*The Question of Realism*, 2001; *The Pure Logic of Ground*, 2012). His work is characterized by technical sophistication, philosophical breadth, and independence from current orthodoxy. M.Du.

finitary proof. See HILBERT'S PROGRAM.

finite automaton. See COMPUTER THEORY, TURING MACHINE.

finitism. See HILBERT, PHILOSOPHY OF MATHEMATICS.

fink, spoken of in relation to masks, designating factors that suppress or mimic the manifestation of a disposition, frustrating attempts to analyze that disposition in terms of a subjunctive conditional. The terms 'fink' and 'mask' are due respectively to C. B. Martin's "Dispositions and Conditionals" (1994) and Mark Johnston's "How to Speak of the Colors" (1992). In "finkish cases" the intrinsic structure of an object is altered to remove or bestow a disposition whenever the object is in just those circumstances that trigger a manifestation in that disposition. For example, a fink might remove the fragility of an ice sculpture by suddenly melting it just as it is struck, or freeze a non-fragile stream of water just as it is struck. In contrast, "masking" and "mimicking" don't rely on intrinsic change; instead, they involve objects that either fail to manifest a disposition they have (in "masking" cases) or exhibit manifestation-behavior for a disposition they lack (in "mimicking" cases) due to a special feature of the external circumstances. For example, a fragile glass might be protected by a sorcerer who would instantly turn to mush anything that came into contact with it, masking its fragility.

Or a non-fragile block of concrete might be hated by a sorcerer, who would greatly magnify the force and rigidity of anything that came into contact with it, mimicking fragility.

Cases like these cause trouble for the attempt to analyze dispositions in terms of conditionals by offering biconditionals with a dispositional ascription on one side and a subjunctive conditional on the other, most paradigmatically of the form 'x is disposed to V in C if and only if x would V in C'. For example, the above cases will constitute counterexamples to such an analysis if we replace 'is fragile' with a predicate that is explicit about the relevant manifestation conditions, such as 'is disposed to break when struck'. Whether more complex conditional analyses might be capable of overcoming this problem remains a debated issue.

Finnish philosophy, philosophy developed during the past few centuries. When the first university in Finland was established in 1640 as the Royal Academy of Turku, its Faculty of Arts had two chairs in philosophy: theoretical (teaching logic and metaphysics) and practical (teaching ethics and politics). Thereby philosophy had a significant position in education in the art of thinking and in moral virtues. The Academy was for a long time dominated by a mixture of Lutheran and neo-Scholastic orthodoxy, but philosophers were able to transmit to the learned community important intellectual trends like Ramistic logic, Cartesianism, Bacon's experimental research methods, Wolff's rationalism, Locke's empiricism, Pufendorf's doctrine of natural rights, and Kant's transcendental idealism.

In 1809 Finland was separated from Sweden to become a grand duchy of the Russian Empire, and in 1828 the Academy was moved to the new capital, Helsinki. The Imperial Alexander University in Helsinki adopted the Humboldtian model of university education: the humanities – in particular philosophy and history – replaced traditional theology as academically central. During this period the breakthrough of Hegel's doctrines enabled Johan Vilhelm Snellman (1806–81) to make an important contribution to current international philosophical discussions: through his treatise on the "idea of personality," written in 1841 in Tübingen, he participated in the debates on the philosophy of religion in the Hegelian school. In 1842 he produced a theory of the state upon Hegelian principles, arguing that historical reason is realized through a "national spirit," which he linked with language and culture. Thereby Snellman, traditionally honored and praised as the "national philosopher" of Finland, provided a theoretical foundation for national awakening, which he championed in journals that he established and edited.

By contrast with Snellman, Wilhelm Bolin (1832–1920) was an advanced but lonely representative of philosophical materialism. Bolin, who worked for four decades as the chief librarian in Helsinki, became internationally known as a friend of Feuerbach and the editor of his collected works.

Snellman's chair – at the time the only philosophy professorship in Finland – was inherited in 1869 by his disciple Thiodolf Rein (1838–1919). He encouraged open discussion about novel trends in philosophy and psychology, founding, in 1873, the Philosophical Society. He wrote the first textbooks on logic and psychology in Finnish in the 1880s. Rein's pupils Hjalmar Neiglick (1860–89) and Arvi Grotenfelt (1863–1941) visited Wundt's new laboratory in Leipzig in the 1880s, and defended their doctoral dissertations in experimental psychology. Rein's work as professor of theoretical philosophy was continued in 1905 by his nephew Grotenfelt, a specialist in German philosophy of history. During Grotenfelt's period, Finland gained its independence in 1917, and the Philosophical Society of Finland started to publish its yearbook with the title *Ajatus* ("Thought") in 1926 and a monograph series *Acta Philosophica Fennica* in 1935.

Edward Westermarck (1862–1939), who was appointed professor of practical philosophy in Helsinki in 1906, was already famous for his studies in the history of marriage (1889) and the origins of moral ideas (1906–1908). Westermarck, who had adopted the British empiricism and naturalism associated with the theory of evolution, was at the same time professor of sociology at the London School of Economics and an anthropological fieldworker in Morocco. Together with his pupil Rolf Lagerborg (1874–1959) he was active early in the century in a radical anti-clerical association, Prometheus. Westermarck believed that modest moral relativism supports tolerance in society. His pupil Rafael Karsten (1879–1956) studied Inca culture in Peru, and Gunnar Landtman (1878–1940) Papuans in New Guinea. Westermarck's influence in Finnish philosophy faded away after World War II.

Through Eino Kaila's (1890–1958) charismatic personality, philosophy again gained a prominent academic position. Kaila published in German monographs on causality, probability logic, deduction, and philosophy of nature. From 1929 to 1934 he visited Schlick and Carnap in the Vienna Circle. As professor of theoretical philosophy in Helsinki in 1930–48, Kaila introduced symbolic logic, modern epistemology, philosophy of science, and Gestalt psychology. Kaila – whose father was the archbishop of Finland – directed the critical canons of logical empiricism against traditional metaphysics and religion. On his view, they lack empirically testable "real content", but from the perspective of his psychology of needs (*Persoonallisuus* ["Personality"], 1934), they are expressions of "mental insurance policies" against the fear of death. He never accepted the narrowly positivist views of some in the Vienna Circle, but emphasized the "synthetic" task of philosophy in formulating a realist and comprehensive world outlook on the basis of best scientific theories. Kaila, who served after Grotenfelt as the president of the Philosophical Society of Finland in 1936–52, was elected as one of the twelve members of the Academy of Finland in 1948, the year psychology was separated from theoretical philosophy at the University of Helsinki.

Even though other currents of philosophy, such as cultural philosophy and phenomenology in the German style, had their representatives in new Finnish universities – especially Erik Ahlman (1892–1952) in Jyväskylä, J. E. Salomaa (1891–1960), and Sven Krohn (1903–99) in Turku – the Anglo-Saxon analytic tradition became the dominant school through Kaila's successful students. Oiva Ketonen (1913–2000), Kaila's successor in theoretical philosophy in 1951–77, moved from mathematical logic and philosophy of science to university politics; G. H. von Wright (1916–2003) combined in his career influences of Kaila and Wittgenstein. The young von Wright's period as Wittgenstein's successor at the University of Cambridge (1948–51) was the real international breakthrough of Finnish philosophers. After returning to Finland, von Wright wrote studies in philosophical logic, action theory, and philosophy of science. Erik Stenius (1911–90) contributed in philosophy of language. Von Wright's student Jaakko Hintikka (b.1929), who was appointed professor of practical philosophy in Helsinki 1959 but has been mostly active in the United States, is widely known for his work in philosophical logic, epistemic logic, possible-worlds semantics, inductive logic, philosophy of language, and game-theoretic semantics.

Hintikka has been extremely active in supervising research work in logic and philosophy. Risto Hilpinen (b.1943, Krohn's successor in Turku), Raimo Tuomela (b.1940), Juhani Pietarinen (b.1938), Ilkka Niiniluoto (b.1946, Ketonen's successor in Helsinki, President of the Philosophical Society of Finland after Ketonen and von Wright since 1975), and Matti Sintonen (b.1951) have worked on philosophy of science; Juha Manninen (b.1945) and Simo Knuuttila (b.1946) on the history of philosophy; and Veikko Rantala (b.1933, Kauppi's successor in Tampere), Esa Saarinen (b.1953), and Gabriel Sandu (b.1954) on philosophical logic.

Raili Kauppi (1920–95), the first woman to defend a doctoral dissertation in philosophy in the Nordic countries, analyzed Leibniz's logic. Logic and its history have also been studied by Ingmar Pörn (b.1935), Jan von Plato (b.1951), and Leila Haaparanta (b.1954). Philosophy of the social sciences is the field of Eerik Lagerspetz (b.1956), Uskali Mäki (b.1952), and Petri Ylikoski (b.1969).

Knuuttila is an expert on ancient and medieval philosophy. Jussi Tenkku (1917–2005) studied the history of ethics, Reijo Wilenius (b.1930) studied political philosophy, and Juha Sihvola (1957–2012) applied his knowledge of the Aristotelian tradition to issues in contemporary social philosophy. The history of early modern philosophy is investigated by Lilli Alanen (b.1941) and Olli Koistinen (b.1956). Later Wittgensteinian ideas are developed by Lars Hertzberg (b.1941), and pragmatism by Sami Pihlström (b.1969) and Ahti-Veikko Pietarinen (b.1971).

New trends in applied ethics and bioethics have been promoted by Timo Airaksinen (b.1947), his students Heta Gylling (b.1955) and Matti Häyry (b.1956), and Juha Räikkä (b.1965). Links between Continental and analytic trends have been forged by many philosophers in Finland. Examples include von Wright's analytical hermeneutics, Hintikka's perspectives on Kant and Husserl, and Saarinen's Sartrean existentialist account of "magnificent life."

Ever since Snellman, Finnish philosophers have been active in public cultural debates outside the academic world. Philosophical life is enhanced by high-quality translations of important classics, from Plato and Aristotle via Leibniz and Kant to Wittgenstein and contemporary French thinkers. "Life-stance education," taught since 1985 for non-religious students in schools, has contained a lot of philosophical material, and since 1995 philosophy has been an obligatory subject in high schools.

fitness. See PHILOSOPHY OF BIOLOGY.

fittingness, a normative relation that obtains when, e.g., an action performed by an agent in a particular situation constitutes an appropriate, reasonable, or required response to select aspects of the situation – aspects that count as reasons that overall favor that action. An action is unfitting, then, when it constitutes an inappropriate response to select aspects of some situation – aspects that, e.g., count overall as reasons against the action. The relation of fittingness is not restricted to actions; other attitudes such as beliefs, desires, decisions, and emotions can be fitting (or unfitting) in relation to certain circumstances. Believing on a certain occasion that it is cloudy outside is a fitting response (barring unusual circumstances) to the visual experience one has in looking up at the sky and its appearing cloudy. Taking pleasure in someone's undeserved misfortune constitutes an unfitting response to it. Fittingness is typically considered an irreducible relation, an understanding of which is by way of example together with the use of near synonyms like 'reasonable' and 'appropriate'.

In ethics, some hold that fittingness can be used to provide illuminating, non-circular analyses of ethical concepts (and associated properties). For instance, according to *fittingness analyses* of value, the intrinsic value of some item is to be understood as its having certain good-making features in response to which a certain pro-attitude such as desiring it for its own sake is a fitting response. Some philosophers offer fittingness attitude analyses of deontic concepts such as rightness and wrongness, and some offer such analyses of both evaluative and deontic concepts. Among the most serious problems for these analyses is the *wrong kind of reasons* objection. Suppose an evil demon (who clearly lacks features that would make him admirable) were to threaten you with torture unless you admire him. Arguably his threat provides you with a reason to admire him – a prudential reason – but not a reason that shows he is admirable. Only reasons of the right kind, then, can figure in fitting analyses of moral concepts. Whether it is possible to distinguish right from wrong kinds of reason on behalf of fitting attitude analyses, and if so, how, remains an outstanding challenge to such views.

Florenski, Pavel Aleksandrovich (1882–1937), Russian philosopher, theologian, art theoretician, and scientist-polymath. After graduating from the Department of Physics and Mathematics of Moscow University (1904), he graduated from Moscow Theological Academy (1908) and was ordained a priest (1911). In *The Pillar and Ground of the Truth* (1914) he expounded a new philosophical system that follows the ancient line of metaphysics of All-Unity found in Neoplatonism, Nicolas of Cusa, and Schelling. Like Vladimir Soloviev, Florenski associated the basic concept of All-Unity with the biblical and gnostic mythologem of Sophia, the Wisdom of God, so that his philosophy becomes "sophiology," very different, however, from that of Soloviev. Florenski's approach integrates epistemology into ontology and introduces rich Christian contents to philosophical discourse.

Later, Florenski developed a broad project of symbolistic philosophy called "concrete metaphysics" resembling Cassirer's theory of symbolic forms. He planned to provide a set of studies of reality as formed by symbols: the study of visual symbols included a specific model of the cosmos and a general theory of space in plastic arts; the study of acoustic symbols produced a philosophy of language based on the idea of occult energies hidden in words, etc. These studies contained many pioneering ideas but were published only in the post-Soviet period. S.Kh.

Fludd, Robert (1574–1637), English physician and writer. Influenced by Paracelsus, hermetism, and the cabala, Fludd defended a Neoplatonic worldview on the eve of its supersession by the new mechanistic philosophy. He produced improvements in the manufacture of steel and invented a thermometer, though he also used magnets to cure disease and devised a salve to be applied to a weapon to cure the wound it had inflicted. He held that science got its ideas from Scripture allegorically interpreted, when they were of any value. His works combine theology with an occult, Neoplatonic reading of the Bible, and contain numerous fine diagrams illustrating the mutual sympathy of human beings, the natural world, and the supernatural world, each reflecting the others in parallel harmonic structures. In controversy with Kepler, Fludd claimed to uncover essential natural processes rooted in natural sympathies and the operation of God's light, rather than merely describing the external movements of the heavens. Creation is the extension of divine light into matter. Evil arises from a darkness in God, his failure to will. Matter is uncreated, but this poses no problem for orthodoxy, since matter is nothing, a mere possibility without the least actuality, not *something* coeternal with the Creator. **See also** NEOPLATONISM.

Fodor, Jerry A. (b.1935), influential contemporary American philosopher of psychology, known for his energetic (and often witty) defense of intensional realism, a computational-representational model of thought, and an atomistic, externalist theory of content determination for mental states. Fodor's philosophical writings fall under three headings. First, he has defended the theory of mind implicit in contemporary cognitive psychology, that the cognitive mind-brain is both a representational/computational device and, ultimately, physical. He has taken on behaviorists (Ryle), psychologists in the tradition of J. J. Gibson, and eliminative materialists (P. A. Churchland). Second, he has engaged in various theoretical disputes within cognitive psychology, arguing for the modularity of the perceptual and language systems (roughly, the view that they are domain-specific, mandatory, limited-access, innately specified, hardwired, and informationally encapsulated) (*The Modularity of Mind*, 1983); for a strong form of nativism (that virtually all of our concepts are innate); and for the existence of a "language of thought" (*The Language of Thought*, 1975). The latter has led him to argue against connectionism as a psychological theory (as opposed to an implementation theory).

Finally, he has defended the views of ordinary propositional attitude psychology that our mental states (1) are semantically evaluable (intentional), (2) have causal powers, and (3) are such that the implicit generalizations of folk psychology are largely true of them. His defense is twofold. Folk psychology is unsurpassed in explanatory power; furthermore, it is vindicated by contemporary cognitive psychology insofar as ordinary propositional attitude states can be identified with information-processing states, those that consist in a computational relation to a representation. The representational component of such states allows us to explain the semantic evaluability of the attitudes; the computational component, their causal efficacy. Both sorts of accounts raise difficulties. The first is satisfactory only if supplemented by a naturalistic account of representational content. Here Fodor has argued for an atomistic, externalist causal theory (*Psychosemantics*, 1987) and against holism (the view that no mental representation has content unless many other non-synonymous mental representations also have content) (*Holism: A Shopper's Guide*, 1992), against conceptual role theories (the view that the content of a representation is determined by its conceptual role) (Ned Block, Brian Loar), and against teleofunctional theories (teleofunctionalism is the view that the content of a representation is determined, at least in part, by the biological functions of the representations themselves or systems that produce or use those representations) (Ruth Millikan, David

Papineau). The second sort is satisfactory only if it does not imply epiphenomenalism with respect to content properties. To avoid such epiphenomenalism, Fodor has argued that not only strict laws but also *ceteris paribus* laws can be causal. In addition, he has sought to reconcile his externalism vis-à-vis content with the view that causal efficacy requires an individualistic individuation of states. Two solutions have been explored: the supplementation of broad (externally determined) content with narrow content, where the latter supervenes on what is "in the head" (*Psychosemantics*, 1987), and its supplementation with modes of presentation identical to sentences of the language of thought (*The Elm and the Expert*, 1995). More recent books include *The Compositionality Papers*, with Ernest LePore (2002) and *Hume Variations* (2003).

B.V.E.

folk psychology, in one sense, a putative network of principles constituting a commonsense theory that allegedly underlies everyday explanations of human behavior; the theory assigns a central role to mental states like belief, desire, and intention. Consider an example of an everyday commonsense psychological explanation: Jane went to the refrigerator because she wanted a beer and she believed there was beer in the refrigerator. Like many such explanations, this adverts to a so-called propositional attitude – a mental state, expressed by a verb ('believe') plus a that-clause, whose intentional content is propositional. It also adverts to a mental state, expressed by a verb ('want') plus a direct-object phrase, whose intentional content appears *not* to be propositional.

In another, related sense, folk psychology is a network of social practices that includes ascribing such mental states to ourselves and others, and proffering explanations of human behavior that advert to these states. The two senses need distinguishing because some philosophers who acknowledge the existence of folk psychology in the second sense hold that commonsense psychological explanations do not employ empirical generalizations, and hence that there is no such *theory* as folk psychology. (Henceforth, 'FP' will abbreviate 'folk psychology' in the first sense; the unabbreviated phrase will be used in the second sense.)

Eliminativism in philosophy of mind asserts that FP is an empirical theory; that FP is therefore subject to potential scientific falsification; and that mature science very probably will establish that FP is so radically false that humans simply do not undergo mental states like beliefs, desires, and intentions. One kind of eliminativist argument first sets forth certain methodological strictures about how FP would have to integrate with mature science in order to be true (e.g., being smoothly reducible to neuroscience or being absorbed into mature cognitive science), and then contends that these strictures are unlikely to be met. Another kind of argument first claims that FP embodies certain strong empirical commitments (e.g., to mental representations with language-like syntactic structure), and then contends that such empirical presuppositions are likely to turn out false.

One influential version of folk-psychological realism largely agrees with eliminativism about what is required to vindicate folk psychology, but also holds that mature science is likely to provide such vindication. Realists of this persuasion typically argue, for instance, that mature cognitive science will very likely incorporate FP, and also will very likely treat beliefs, desires, and other propositional attitudes as states with language-like syntactic structure. Other versions of folk-psychological realism take issue, in one way or another, with either (i) the eliminativists' claims about FP's empirical commitments, or (ii) the eliminativists' strictures about how FP must mesh with mature science in order to be true, or both. Concerning (i), for instance, some philosophers maintain that FP per se is not committed to the existence of language-like mental representations. If mature cognitive science turns out not to posit a "language of thought," they contend, this would not necessarily show that FP is radically false; instead it might only show that propositional attitudes are subserved in some other way than via language-like representational structures.

Concerning (ii), some philosophers hold that FP can be true without being as tightly connected to mature scientific theories as the eliminativists require. For instance, the demand that the special sciences be smoothly reducible to the fundamental natural sciences is widely considered an excessively stringent criterion of intertheoretic compatibility; so perhaps FP could be true without being smoothly reducible to neuroscience. Similarly, the demand that FP be directly absorbable into empirical cognitive science is sometimes considered too stringent a criterion either of FP's truth, or of the soundness of its ontology of beliefs, desires, and other propositional attitudes, or of the legitimacy of FP-based explanations of behavior. Perhaps FP is a true theory, and explanatorily legitimate, even if it is not destined to become a part of science. Even if FP's ontological categories are not scientific natural kinds, perhaps its generalizations are like generalizations about clothing: true, explanatorily usable, and ontologically sound. (No one doubts the existence of hats, coats, or scarves. No one doubts the truth or explanatory utility of generalizations like 'Coats made of heavy material tend to keep the body warm in cold weather', even though these generalizations are not laws of any science.)

Yet another approach to folk psychology, often wedded to realism about beliefs and desires (although sometimes wedded to instrumentalism), maintains that folk psychology does not employ empirical generalizations, and hence is not a *theory* at all. One variant denies that folk psychology employs *any* generalizations, empirical or otherwise. Another variant concedes that there are folk-psychological generalizations, but denies that they are empirical; instead they are held to be analytic truths, or norms of rationality, or both at once. Advocates of non-theory views typically regard folk psychology as a hermeneutic, or interpretive, enterprise. They often claim too that the attribution of propositional attitudes, and also the proffering and grasping of folk-psychological explanations, is a matter of imaginatively projecting oneself into another person's situation, and then experiencing a kind of empathic understanding, or *Verstehen*, of the person's actions and the motives behind them. A more recent, hi-tech formulation of this idea is that the interpreter "runs a cognitive simulation" of the person whose actions are to be explained.

Philosophers who defend folk-psychological realism, in one or another of the ways just canvassed, also sometimes employ arguments based on the allegedly self-stultifying nature of eliminativism. One such argument begins from the premise that the notion of action is folk-psychological – that a behavioral event counts as an action only if it is caused by propositional attitudes that rationalize it (under some suitable act-description). If so, and if humans never really undergo propositional attitudes, then they never really *act* either. In particular, they never really *assert* anything or *argue* for anything (since asserting and arguing are species of action). So if eliminativism is true, the argument concludes, then eliminativists can neither assert it nor argue for it – an allegedly intolerable pragmatic paradox. Eliminativists generally react to such arguments with breathtaking equanimity. A typical reply is that although our present concept of action might well be folk-psychological, this does not preclude the possibility of a future successor concept, purged of any commitment to beliefs and desires, that could inherit much of the role of our current, folk-psychologically tainted concept of action.

Føllesdal, Dagfinn (b.1932), Norwegian philosopher who is a pioneer in modal logic and theory of reference and an important mediator between "Continental" and analytic philosophy. A distinguished interpreter of the work of both Husserl and Quine, he has also contributed to ethics, action theory, and philosophy of science. His pioneering *Husserl und Frege* (1958), like many of his later writings, concerns the relation between phenomenology and analytic philosophy. His much-discussed "Husserl's Notion of Noema" (1969) sketches his "Fregean reading" of a central notion in Husserl's view of intentionality. His Ph.D. thesis, *Referential Opacity and Modal Logic* (1961), supervised by Quine, was the first work to postulate and argue for what were later known as "rigid designators," terms that allow (*pace* Quine) quantifying into modal contexts, such as 'Aristotle could have become a politician'. Føllesdal later wrote several contributions on Quine's and Davidson's philosophy, as well as much-quoted papers such as "Knowledge, Identity and Existence" and "Quantification into Causal Contexts."

His books include a textbook, *Argumentation and the Philosophy of Science* (with Lars Walløe and Jon Elster) and (as editor) *The Philosophy of W. V. Quine* (five volumes). What is probably more significant, apart from his worldwide teaching and lecturing, are his research articles. "Hermeneutics and the Hypothetico-deductive Method," e.g., initiated a new approach to the theory of humanities, sometimes referred to as naturalistic hermeneutics.

Føllesdal studied mathematics in Oslo and Göttingen and philosophy at Harvard. From 1967 to his retirement, he was Professor of Philosophy at the University of Oslo. He also taught at Stanford University (1967–2010), edited the *Journal of Symbolic Logic* (1970–82), and in 1993 became president of the Norwegian Academy of Science. Føllesdal is at home in different philosophical traditions and, on one view, it is due not least to him that the "analytic-Continental split" now largely belongs to history.

Fonseca, Pedro da (1528–99), Portuguese philosopher and logician. He entered the Jesuit order in 1548. Apart from a period (1572–82) in Rome, he lived in Portugal, teaching philosophy and theology at the Universities of Evora and Coimbra and performing various administrative duties for his order. He was responsible for the idea of a published course on Aristotelian philosophy, and the resulting series of Coimbra commentaries, the *Cursus Conimbricensis*, was widely used in the seventeenth century. His own logic text, the *Institutes of Dialectic* (1564), went into many editions. It is a good example of Renaissance Aristotelianism, with its emphasis on Aristotle's syllogistic, but it retains some material on medieval developments, notably consequences, exponibles, and supposition theory. Fonseca also wrote a commentary on Aristotle's *Metaphysics* (published in parts from 1577 on), which contains the Greek text, a corrected Latin translation, comments on textual matters, and an extensive exploration of selected philosophical problems. He cites a wide range of medieval philosophers, both Christian and Arab, as well as the newly published Greek commentators on Aristotle. His own position is sympathetic to Aquinas, but generally independent. Fonseca is important not so much for any particular doctrines, though he did hold original views on such matters as analogy, but for his provision of fully documented, carefully written, and carefully argued books that, along with others in the same tradition, were read at universities, both Catholic and Protestant, well into the seventeenth century. He represents what is often called the Second Scholasticism. E.J.A.

Fontenelle, Bernard Le Bovier de (1657–1757), French writer who heralded the age of the *philosophes*. A product of Jesuit education, he was a versatile freethinker with skeptical inclinations. *Dialogues of the Dead* (1683) showed off his analytical mind and elegant style. In 1699, he was appointed secretary of the Academy of Sciences. He composed famous eulogies of scientists; defended the superiority of modern science over tradition in *Digression on Ancients and Moderns* (1688); popularized Copernican astronomy in *Conversations on the Plurality of Worlds* (1686) – famous for postulating the inhabitation of planets; stigmatized superstition and credulity in *History of Oracles* (1687) and *The Origin of Fables* (1724); promoted Cartesian physics in *The Theory of Cartesian Vortices* (1752); and wrote *Elements of Infinitesimal Calculus* (1727) in the wake of Newton and Leibniz. J.-L.S.

food ethics, the subfield of applied ethics addressing the moral questions concerning the production, distribution, marketing, consumption, and sociocultural significance of food. Food production is a subject of long-standing disputes. One concerns whether and under what conditions the use of animals is wrongful treatment. This has been extensively explored from both animal rights and animal welfare perspectives. Another dispute, bearing on both individual and environmental health, concerns organic agriculture and the appropriate use of pesticides and herbicides. Much current controversy concerns "GM foods" produced from genetically modified organisms (typically crops). The promised benefits of GM foods are morally significant: improved yield, increased food security, more efficient use of natural resources, and improved resistance to disease and herbicides. Critics, however, argue that GM crops and foods pose significant known and unknown risks for humans and the environment. Additionally, given the proprietary nature of biotechnology, widespread production of GM crops raises concerns about intellectual property rights and the dependence of developing countries on the agricultural biotech industry. Finally, as food demand increases with global population growth, ethical issues arise concerning the appropriate use in food production of relatively scarce natural resources such as arable land and fresh water. Some argue that the copious water required for raising feedlot cattle should be more efficiently used to produce crops.

Food distribution raises traditional questions concerning justice – the extent of our obligations to the poor and hungry. In addition, the typically significant distance from farm to plate poses a number of moral issues concerning the environmental, economic, and cultural impact of so-called food-miles. With respect to food marketing, an important dispute concerns packaging and the extent to which food marketers are obligated to provide information about a food's origin (e.g., whether a chicken was humanely raised), nature (e.g., whether a tomato was derived from a GM crop), or preparation (e.g., whether a strawberry was irradiated). Questions also concern the appropriateness of child-targeted advertisements for typically unhealthy food – questions made urgent by rising childhood obesity.

Food consumption also raises ethical issues. Central to the ethics of eating are disputes concerning whether one has an obligation – to oneself, others, future generations, animals, and the environment – to eat (or not eat) certain foods or to eat them in a certain manner. Some argue that certain foods should be avoided on pain of supporting an unethical agricultural practice. Indeed, some contend that eating is an inherently political statement – that you "vote with your fork." More general, perhaps, are questions concerning the role of eating, feasting, and perhaps even fasting in the good life.

Finally, sociocultural issues in food ethics concern the interplay between food culture and gender, race, and class. Some issues arise in connection with the gender-specific roles and expectations that often attend the acquisition, preparation, and consumption of food. Other issues concern alleged affinities between feminism and vegetarianism, on the one hand, and patriarchy and animal exploitation, on the other.

Foot, Philippa (1920–2010), British philosopher who exerted a lasting influence on the development of moral philosophy in the second half of the twentieth century. Her persisting, intertwined themes are opposition to all forms of subjectivism in ethics, the significance of the virtues and vices, and the connection between morality and rationality. In her earlier papers, particularly "Moral Beliefs" (1958) and "Goodness and Choice" (1961), reprinted in her *Virtues and Vices* (1978), she undermines the subjectivist accounts of moral "judgment" derived from Stevenson and Hare, by arguing for many logical or conceptual connections between evaluations and the factual statements on which they must be based. In the final work that crowned her career, she developed this kind of thought into the naturalistic claim that moral evaluations are determined by facts about our life and our nature, as evaluations of features of plants and animals (as good or defective specimens of their kind) are determined by facts about their nature and their life.

Foot's opposition to subjectivism remained constant, but her views on the virtues in relation to rationality underwent several changes. In "Moral Beliefs" she related them to self-interest, maintaining that a virtue must benefit its possessor; in the (subsequently repudiated) "Morality as a System of Hypothetical Imperatives" (1972) she went as far as to deny that there was necessarily anything contrary to reason in being uncharitable or unjust. Never happy with this result, she returned to the topic twenty years later to write her only monograph, *Natural Goodness* (2001). Here she identified our moral evaluations of ourselves as a special case of our evaluations of the "natural goodness" (or the defectiveness) of other living things and reinstated ancient connections between virtue, rationality, and happiness.

force, illocutionary. See PHILOSOPHY OF LANGUAGE, SPEECH ACT THEORY.

forcing, a method introduced by Paul J. Cohen – see his *Set Theory and the Continuum Hypothesis* (1966) – to prove independence results in Zermelo-Fraenkel set theory (ZF). Cohen proved the independence of the axiom of choice (AC) from ZF and of the continuum hypothesis (CH) from ZF + AC. The consistency of AC with ZF and of CH with ZF + AC had previously been proved by Gödel using the method of constructible sets. A model of ZF consists of layers, with the elements of a set at one layer always belonging to lower layers. Starting with a model M, Cohen's method produces an "outer model" N with no more levels but with more sets at each level (whereas Gödel's method produces an "inner model" L): much of what will become true in N can be "forced" from within M. The method is applicable only to hypotheses in the more "abstract" branches of mathematics (infinitary combinatorics, general topology, measure theory, universal algebra, model theory, etc.); but there it is ubiquitous. Applications include the proof by Robert M. Solovay of the consistency of the measurability of all sets (of all projective sets) with ZF (with ZF + AC); also the proof by Solovay and Donald A. Martin of the consistency of Martin's axiom (MA) plus the negation of the continuum hypothesis (~CH) with ZF + AC. (CH implies MA; and of known consequences of CH about half are implied by MA, about half refutable by MA + ~CH.) Numerous simplifications, extensions, and variants (e.g., Boolean-valued models) of Cohen's method have been introduced. **See also** INDEPENDENCE RESULTS, SET THEORY. J.Bur.

Fordyce, David (1711–51), Scottish philosopher and educational theorist whose writings were influential in the eighteenth century. His lectures formed the basis of his *Elements of Moral Philosophy*, written originally for *The Preceptor* (1748), later translated into German and French, and abridged for the articles on moral philosophy in the first *Encylopaedia Britannica* (1771). Fordyce combines the preacher's appeal to the heart in the advocacy of virtue with a moral "scientist's" appraisal of human psychology. He claims to derive our duties experimentally from a study of the prerequisites of human happiness. M.A.St.

foreknowledge, divine. See DIVINE FOREKNOWLEDGE.

forgiveness, one possible response to an agent's moral failing (or apparent moral failing), wherein another party (a) experiences a reduction in (or the absence of) anger, resentment, or a similar emotion that might have been caused by the moral failing; (b) acts toward the transgressor in a way that is not motivated by such an emotion; or (c) does not hold the moral failing against the transgressor. One broad question dividing philosophers is whether each of these conditions must be met for a response to count as an instance of forgiveness or whether only one or two of them are necessary. Some argue that an agent who refuses to allow her anger to determine how she treats a transgressor has forgiven him, even if she still feels anger toward him, whereas others insist that her anger must be eliminated altogether before she has forgiven him. A second broad question about which there is considerable debate is whether other conditions must be met for a response to count as an instance of forgiveness. For example, some assume that the relevant moral failing must be a wrongful act, whereas others argue that an agent can be forgiven for failures of character as well. Some add the condition that the forgiver must have been a victim of the transgressor's moral failing, whereas others argue that third parties who were not victims can also forgive. Some wish to add the restoration of a relationship between the relevant parties as a necessary condition of forgiveness, whereas others argue that one can forgive without reconciling and reconcile without forgiving. A third broad question, about which there has been considerable disagreement, concerns when it is appropriate to forgive. Some have contended that a transgressor must sincerely apologize and attempt to make amends before it is appropriate to forgive him. Some have even made such actions a definitional precondition for forgiveness. Others have defended the possibility and permissibility of forgiving transgressors before they have repented or made amends. Some have held that some agents' moral failings are so great that they can (or may) never be forgiven, whereas others have insisted that no agent is unforgivable. Finally, there are the questions of whether forgiveness is something that can take place only between individuals or whether groups can (or may) also forgive and, if so, how group forgiveness is like or unlike individual forgiveness. **See also** MERCY. G.P.

form, in metaphysics, especially Plato's and Aristotle's, the structure or essence of a thing as contrasted with its matter.

(1) Plato's *theory of Forms* is a realistic ontology of universals. In his elenchus, Socrates sought what is common to, e.g., all chairs. Plato believed there must be an essence – or Form – common to everything falling under one concept, which makes anything what it is. A chair is a chair because it "participates in" the Form of Chair. The Forms are ideal "patterns," unchanging, timeless, and perfect. They exist in a world of their own (cf. the Kantian noumenal realm). Plato speaks of them as self-predicating: the Form of Beauty is perfectly beautiful. This led, as he realized, to the *Third Man argument* that there must be an infinite number of Forms. The only true understanding is of the Forms. This we attain through *anamnesis*, "recollection."

(2) Aristotle agreed that forms are closely tied to intelligibility, but denied their separate existence. Aristotle explains change and generation through a distinction between the form and matter of substances. A lump of bronze (matter) becomes a statue through its being molded into a certain shape (form). In his earlier metaphysics, Aristotle identified primary substance with the composite of matter and form, e.g. Socrates. Later, he suggests that primary substance is form – what makes Socrates what he is (the form here is his soul). This notion of forms as essences has obvious similarities with the Platonic view. They became the "substantial forms" of Scholasticism, accepted until the seventeenth century.

(3) Kant saw form as the a priori aspect of experience. We are presented with phenomenological "matter," which has no meaning until the mind imposes some form upon it.

formal epistemology, the formal study of crucial concepts in mainstream and social epistemology, including knowledge, belief and belief-change, certainty, rationality, reasoning, decision, justification, learning, agent interaction, group agency, institutional knowledge, collective rationality, and information processing. The formal tools may be drawn from a wide variety of areas, including logic, probability theory, game theory, decision theory, formal learning theory, and distributed computing, and thus formal epistemology is not a purely philosophical province. Its practitioners include philosophers, computer scientists, social scientists, cognitive psychologists, theoretical economists, mathematicians, and theoretical linguists. Formal epistemology is a fairly recent field of study in philosophy dating back to the end of the twentieth century. This is not to say that no formal epistemological studies occurred before the late 1990s, but rather that the term introduced to cover the philosophical enterprise was coined around this time.

One prominent set of tools in formal epistemology is rooted in modal logic, particularly epistemic logic. Epistemic logic started with the study of proper axiomatizations for predicates and operators that represent concepts of knowledge, belief, certainty, and other epistemic attitudes. Today the field is a rich blend of studies ranging from mono-agent and multi-agent axiomatizations of various epistemic attitudes; to models of the interplay between knowledge and games, preferences, actions, and decisions; to active agency, learning, belief revision, the dynamics of information processing, models of agent interaction in multi-agent systems, and combined multi-agent and multi-modal systems.

Epistemic logic also informed a program in theoretical economics called "interactive epistemology." The name denotes the interdisciplinary study of shared knowledge and belief given more than one agent or player in an environment, and the program has close ties to (epistemic) game theory and to questions of common knowledge and belief, backward induction, various forms of game equilibria and strategies in games, (im)perfect information games, (bounded) rationality, etc.

Probability theory comprises another very useful set of methods. Probabilities are used to measure key epistemic components like belief and degrees thereof, as well as the strength of expectations and predictions. They may be used to describe actual occurrent frequencies in nature or in the agent's environment, and to model choice and decision. Probabilities are paramount in accounting for notions of (Bayesian) confirmation. Current cognitive models apply probabilities to representing aggregated experience in tasks involving language acquisition, problem solving, inductive learning, conditionalization, and updating beliefs and scientific hypotheses.

Knowledge has traditionally been considered the crown jewel in epistemology, but some tend to think that knowledge is overrated and that belief may be good enough for action, deliberation, and decision. Belief revision theory, another celebrated tool of the trade, concerns how beliefs should be revised in light of new evidence, as well as how to make creative leaps beyond what is logically implied by available information, and is crucial in agent interaction models representing what agents think about moves, strategies, payoffs, and beliefs of other agents and what agent rationality amounts to.

See also **BAYESIAN EPISTEMOLOGY, COMPUTABILITY, EPISTEMIC LOGIC, EPISTEMOLOGY, SOCIAL EPISTEMOLOGY.** V.F.H.

formal fallacy, an invalid inference pattern that is described in terms of a formal logic. There are three main cases: (1) an invalid (or otherwise unacceptable) argument identified solely by its form or structure, with no reference to the content of the premises and conclusion (such as equivocation) or to other features, generally of a pragmatic character, of the argumentative discourse (such as unsuitability of the argument for the purposes for which it is given, failure to satisfy inductive standards for acceptable argument, etc.; the latter conditions of argument evaluation fall into the purview of informal fallacy); (2) a formal rule of inference, or an argument form, that is not valid (in the logical system on which the evaluation is made), instances of which are sufficiently frequent, familiar, or deceptive to merit giving a name to the rule or form; and (3) an argument that is an instance of a fallacious rule of inference or of a fallacious argument form and that is not itself valid.

The criterion of satisfactory argument typically taken as relevant in discussing formal fallacies is validity. In this regard, it is important to observe that rules of inference and argument forms that are not valid may have instances (which may be another rule or argument form, or may be a specific argument) that *are* valid. Thus, whereas the argument form

(i) P, Q; therefore R

(a form that every argument, including every valid argument, consisting of two premises shares) is not valid, the argument form (ii), obtained from (i) by substituting P & Q for R, is a valid instance of (i):

(ii) P, Q; therefore P & Q.

Since (ii) is not invalid, (ii) is not a formal fallacy though it is an instance of (i). Thus, some instances of formally fallacious rules of inference or argument-forms may be valid and therefore not be formal fallacies. Examples of formal fallacies follow below, presented according to the system of logic appropriate to the level of description of the fallacy. There are no standard names for some of the fallacies listed.

Fallacies of sentential (propositional) logic

Affirming the consequent: If p then q; q / $\therefore$ p.

> If Richard had his nephews murdered, then Richard was an evil man; Richard was an evil man. Therefore, Richard had his nephews murdered.

Denying the antecedent: If p then q; not-p / $\therefore$ not-q.

> If North was found guilty by the courts, then North committed the crimes charged of him; North was not found guilty by the courts. Therefore, North did not commit the crimes charged of him.

Commutation of conditionals*:* If p then q / $\therefore$ If q then p.

> If Reagan was a great leader, then so was Thatcher. Therefore, if Thatcher was a great leader, then so was Reagan.

Improper transposition: If p then q / $\therefore$ If not-p then not-q.

> If the nations of the Middle East disarm, there will be peace in the region. Therefore, if the nations of the Middle East do not disarm, there will not be peace in the region.

Improper disjunctive syllogism (affirming one disjunct): p or q; p / $\therefore$ not-q.

> Either John is an alderman or a ward committeeman; John is an alderman. Therefore, John is not a ward committeeman. (This rule of inference would be valid if 'or' were interpreted exclusively, where 'p or$_{\text{EX}}$ q' is true if exactly one constituent is true and is false otherwise. In standard systems of logic, however, 'or' is interpreted inclusively.)

Fallacies of syllogistic logic

Fallacies of distribution (where M is the middle term, P is the major term, and S is the minor term).

Undistributed middle term: the middle term is not distributed in either premise (roughly, nothing is said of all members of the class it designates), as in

Some P are M.	Some politicians are crooks.
Some M are S.	Some crooks are thieves.
$\therefore$ Some S are P.	$\therefore$ Some politicians are thieves.

Illicit major (*undistributed major term*): the major term is distributed in the conclusion but not in the major premise, as in

All M are P.	All radicals are communists.
No S are M.	No socialists are radicals.
$\therefore$ Some S are not P.	$\therefore$ Some socialists are not communists.

Illicit minor (*undistributed minor term*)*:* the minor term is distributed in the conclusion but not in the minor premise, as in

All P are M.	All neo-Nazis are radicals.
All M are R.	All radicals are terrorists.
$\therefore$ All S are P.	$\therefore$ All terrorists are neo-Nazis.

Fallacies of negation

Two negative premises (*exclusive premises*): the syllogism has two negative premises, as in

No M are P.	No racist is just.
Some M are not S.	Some racists are not police.
$\therefore$ Some S are not P.	$\therefore$ Some police are not just.

Illicit negative/affirmative: the syllogism has a negative premise (conclusion) but no negative conclusion (premise), as in

All *M* are *P*.	All liars are deceivers.
Some *M* are not *S*.	Some liars are not aldermen.
∴ Some *S* are *P*.	∴ Some aldermen are deceivers.

and

All *P* are *M*.	All vampires are monsters.
All *M* are *S*.	All monsters are creatures.
∴ Some *S* are not *P*.	∴ Some creatures are not vampires.

Fallacy of existential import: the syllogism has two universal premises and a particular conclusion, as in

All *P* are *M*.	All horses are animals.
No *S* are *M*.	No unicorns are animals.
∴ Some *S* are not *P*.	∴ Some unicorns are not horses.

A syllogism can commit more than one fallacy. For example, the syllogism

Some *P* are *M*.
Some *M* are *S*.
∴ No *S* are *P*.

commits the fallacies of undistributed middle, illicit minor, illicit major, and illicit negative/affirmative.

Fallacies of predicate logic

Illicit quantifier shift: inferring from a universally quantified existential proposition to an existentially quantified universal proposition, as in

$$(\forall x)(\exists y)Fxy/\therefore(\exists y)(\forall x)Fxy$$

Everyone is irrational at some time (or other) / ∴ At some time, everyone is irrational.

***Some are/some are not* (*unwarranted contrast*):** inferring from 'Some *S* are *P*' that 'Some *S* are not *P*' or inferring from 'Some *S* are not *P*' that 'Some *S* are *P*', as in

$$(\exists x)(Sx\,\&\ Px)/\therefore(\exists y)(Sx\,\&\,{\sim}Px)$$

Some people are left-handed / ∴ Some people are not left-handed.

Illicit substitution of identicals: where ϕ is an opaque (oblique) context and α and β are singular terms, to infer from $\phi\alpha;\ \alpha = \beta\ /\ \therefore\ \phi\beta$, as in

The inspector believes Hyde is Hyde; Hyde is Jekyll / ∴ The inspector believes Hyde is Jekyll.

See also EXISTENTIAL IMPORT, LOGICAL FORM, MODAL LOGIC, SYLLOGISM. W.K.W.

formalism, the view that mathematics concerns manipulations of symbols according to prescribed structural rules. It is cousin to nominalism, the older and more general metaphysical view that denies the existence of all abstract objects and is often contrasted with Platonism, which takes mathematics to be the study of a special class of non-linguistic, non-mental objects, and intuitionism, which takes it to be the study of certain mental constructions. In sophisticated versions, mathematical activity can comprise the study of possible formal manipulations within a system as well as the manipulations themselves, and the "symbols" need not be regarded as either linguistic or concrete. Formalism is often associated with the mathematician David Hilbert. But Hilbert held that the "finitary" part of mathematics, including, e.g., simple truths of arithmetic, describes indubitable facts about real objects and that the "ideal" objects that feature elsewhere in mathematics are introduced to facilitate research about the real objects. Hilbert's formalism is the view that the *foundations* of mathematics can be secured by proving the consistency of formal systems to which mathematical theories are reduced. Gödel's two incompleteness theorems establish important limitations on the success of such a project. **See also** ABSTRACT ENTITY, AESTHETIC FORMALISM, HILBERT'S PROGRAM, MATHEMATICAL INTUITIONISM, METAPHYSICAL REALISM, PHILOSOPHY OF MATHEMATICS. formalization, an abstract representation of a theory that must satisfy requirements sharper than those imposed on the structure of theories by the axiomatic-deductive method. That method can be traced back to Euclid's *Elements*.

The crucial additional requirement is the regimentation of inferential steps in proofs: not only do axioms have to be given in advance, but the rules representing argumentative steps must also be taken from a predetermined list. To avoid a regress in the definition of proof and to achieve intersubjectivity on a minimal basis, the rules are to be "formal" or "mechanical" and must take into account only the form of statements. Thus, to exclude any ambiguity, a precise and effectively described language is needed to formalize particular theories. The general kind of requirements was clear to Aristotle and explicit in Leibniz; but it was only Frege who, in his *Begriffsschrift* (1879), presented, in addition to an expressively rich language with relations and quantifiers, an adequate logical calculus. Indeed, Frege's calculus, when restricted to the language of predicate logic, turned out to be semantically complete. He provided for the first time the means to formalize mathematical proofs.

Frege pursued a clear philosophical aim, namely to recognize the "epistemological nature" of theorems. In the introduction to his *Grundgesetze der Arithmetik* (1893), Frege wrote: "By insisting that the chains of inference do not have any gaps we succeed in bringing to light every axiom, assumption, hypothesis or whatever else you want to call it on which a proof rests; in this way we obtain a basis for judging the epistemological nature of the theorem." The Fregean frame was used in the later development of mathematical logic, in particular in proof theory. Gödel established through his incompleteness theorems fundamental limits of formalizations of particular theories, like the system of *Principia Mathematica* or axiomatic set theories. The general notion of formal theory emerged from the subsequent investigations of Church and Turing clarifying the concept of 'mechanical procedure' or 'algorithm.' Only then was it possible to state and prove the incompleteness theorems for all formal theories satisfying certain very basic representability and derivability conditions. Gödel emphasized repeatedly that these results do not establish "any bounds for the powers of human reason, but rather for the potentialities of pure formalism in mathematics."

W.S.

formalize, narrowly construed, to formulate a subject as a theory in first-order predicate logic; broadly construed, to describe the essentials of the subject in some formal language for which a notion of consequence is defined. For Hilbert, formalizing mathematics requires at least that there be finite means of checking purported proofs. **See also** FORMALIZATION, PROOF THEORY.

formal justice. See JUSTICE.

formal language, a language in which an expression's grammaticality and interpretation (if any) are determined by precisely defined rules that appeal only to the form or shape of the symbols that constitute it (rather than, e.g., to the intention of the speaker). It is usually understood that the rules are finite and effective (so that there is an algorithm for determining whether an expression is a formula) and that the grammatical expressions are *uniquely readable;* i.e., they are generated by the rules in only one way. A paradigm example is the language of first-order predicate logic, deriving principally from the *Begriffsschrift* of Frege. The grammatical formulas of this language can be delineated by an inductive definition: (1) a capital letter 'F', 'G', or 'H', with or without a numerical subscript, followed by a string of lowercase letters 'a', 'b', and 'c', with or without numerical subscripts, is a formula; (2) if A is a formula, so is $\sim A$; (3) if A and B are formulas, so are $(A \,\&\, B)$, $(A \rightarrow B)$, and $(A \vee B)$; (4) if A is a formula and v is a lowercase letter 'x', 'y', or 'z', with or without numerical subscripts, then $\exists vA'$ and $\forall vA'$ are formulas where A' is obtained by replacing one or more occurrences of some lowercase letter in A (together with its subscripts if any) by v; (5) nothing is a formula unless it can be shown to be one by finitely many applications of the clauses (1)–(4). The definition uses the device of metalinguistic variables: clauses with 'A' and 'B' are to be regarded as abbreviations of all the clauses that would result by replacing these letters uniformly by names of expressions. It also uses several naming conventions: a string of symbols is named by enclosing it within single quotes and also by replacing each symbol in the string by its name; the symbols '$\vee$', '(','')', '&', '$\rightarrow$', '$\sim$' are considered names of themselves. The interpretation of predicate logic is spelled out by a similar inductive definition of truth in a model. With appropriate conventions and stipulations, alternative definitions of formulas can be given that make expressions like '$(P \vee Q)$' the names of formulas rather than formulas themselves. On this approach, formulas need not be written symbols at all and form cannot be identified with shape in any narrow sense. For Tarski, Carnap, and others a formal language also included rules of "transformation" specifying when one expression can be regarded as a consequence of others. Today it is more common to view the language and its consequence relation as distinct. Formal languages are often contrasted with natural languages, like English and Swahili. Richard Montague, however, has tried to show that English is itself a formal language, whose rules of grammar and interpretation are similar to – though much more complex than – predicate logic. **See also** FORMAL LOGIC. S.T.K.

formal learnability theory, the study of human language learning through explicit formal models typically employing artificial languages and simplified learning strategies. The fundamental problem is how a learner is able to arrive at a grammar of a language on the basis of a finite sample of presented sentences (and perhaps other kinds of information as well). The seminal work is by E. Gold (1967), who showed, roughly, that learnability of certain types of grammars from the Chomsky hierarchy by an unbiased learner required the presentation of ungrammatical strings, identified as such, along with grammatical strings. Recent studies have concentrated on other types of grammar (e.g., generative transformational grammars), modes of presentation, and assumptions about learning strategies in an attempt to approximate the actual situation more closely. **See also** GRAMMAR. R.E.W.

formal logic, the science of correct reasoning, going back to Aristotle's *Prior Analytics*, based upon the premise that the validity of an argument is a function of its structure or logical form. The modern embodiment of formal logic is *symbolic* (*mathematical*) *logic*. This is the study of valid inference in artificial, precisely formulated languages, the grammatical structure of whose sentences or well-formed formulas is intended to mirror, or be a regimentation of, the logical forms of their natural language counterparts. These *formal languages* can thus be viewed as (mathematical) models of fragments of natural language. Like models generally, these models are idealizations, typically leaving out of account such phenomena as vagueness, ambiguity, and tense. But the idea underlying symbolic logic is that to the extent that they reflect certain structural features of natural language arguments, the study of valid inference in formal languages can yield insight into the workings of those arguments.

The standard course of study for anyone interested in symbolic logic begins with the (classical) *propositional calculus* (*sentential calculus*), or PC. Here one constructs a theory of valid inference for a formal language built up from a stock of propositional variables (sentence letters) and an expressively complete set of connectives. In the propositional calculus, one is therefore concerned with arguments whose validity turns upon the presence of (two-valued) truth-functional sentence-forming operators on sentences such as (classical) negation, conjunction, disjunction, and the like. The next step is the *predicate calculus* (*lower functional calculus, first-order logic, elementary quantification theory*), the study of valid inference in first-order languages. These are languages built up from an expressively complete set of connectives, first-order universal or existential quantifiers, individual variables, names, predicates (relational symbols), and perhaps function symbols.

Further, and more specialized, work in symbolic logic might involve looking at fragments of the language of the propositional or predicate calculus, changing the semantics that the language is standardly given (e.g., by allowing truth-value gaps or more than two truth-values), further embellishing the language (e.g., by adding modal or other non-truth-functional connectives or higher-order quantifiers), or liberalizing the grammar or syntax of the language (e.g., by permitting infinitely long well-formed formulas). In some of these cases, of course, symbolic logic remains only marginally connected with natural language arguments as the interest shades off into one in formal languages for their own sake, a mark of the most advanced work being done in formal logic today.

formal semantics, the study of the interpretations of formal languages. A formal language can be defined apart from any interpretation of it. This is done by specifying a set of its symbols and a set of formation rules that determine which strings of symbols are grammatical or well formed. When rules of inference (transformation rules) are added and/or certain sentences are designated as axioms, a logical system (also known as a logistic system) is formed. An interpretation of a formal language is (roughly) an assignment of meanings to its symbols and truth conditions to its sentences.

Typically a distinction is made between a standard interpretation of a formal language and a nonstandard interpretation. Consider a formal language in which arithmetic is formulable. In addition to the symbols of logic (variables, quantifiers, brackets, and connectives), this language will contain '0', '+', '•', and 's'. A standard interpretation of it assigns the set of natural numbers as the domain of discourse, zero to '0', addition to '+', multiplication to '•', and the successor function to 's'. Other standard interpretations are isomorphic to the one just given. In particular, standard interpretations are numeral-complete in that they correlate the numerals one-to-one with the domain elements. A result due to Gödel and Rosser is that there are universal quantifications $(x)A(x)$ that are not deducible from the Peano axioms (if those axioms are consistent) even though each $A(n)$ is provable. The Peano axioms (if consistent) are true on each standard interpretation. Thus each $A(n)$ is true on such an interpretation. Thus $(x)A(x)$ is true on such an interpretation since a standard interpretation is numeral-complete. However, there are nonstandard interpretations that do not correlate the numerals one-to-one with domain elements. On some of these interpretations each $A(n)$ is true but $(x)A(x)$ is false.

In constructing and interpreting a formal language we use a language already known to us, say English. English then becomes our metalanguage, which we use to talk about the formal language, which is our object language. Theorems proved within the object language must be distinguished from those proved in the metalanguage. The latter are metatheorems.

One goal of a semantical theory of a formal language is to characterize the consequence relation as expressed in that language and prove semantical metatheorems about that relation. A sentence *S* is said to be a consequence of a set of sentences *K*, provided *S* is true on every interpretation on which each sentence in *K* is true. This notion has to be kept distinct from the notion of deduction. The latter concept can be defined only by reference to a logical system associated with a formal language. Consequence, however, can be characterized independently of a logical system, as was just done.

Foucault, Michel (1926–84), French philosopher and historian of thought. Foucault's earliest writings (e.g., *Maladie mentale et personnalité* ["Mental Illness and Personality"], 1954) focused on psychology and developed within the frameworks of Marxism and existential phenomenology. He soon moved beyond these frameworks, in directions suggested by two fundamental influences: history and philosophy of science, as practiced by Bachelard and (especially) Canguilhem, and the modernist literature of, e.g., Raymond Roussel, Bataille, and Maurice Blanchot. In studies of psychiatry (*Histoire de la folie* ["History of Madness"], 1961), clinical medicine (*The Birth of the Clinic*, 1963), and the social sciences (*The Order of Things*, 1966), Foucault developed an approach to intellectual history, "the archaeology of knowledge," that treated systems of thought as "discursive formations" independent of the beliefs and intentions of individual thinkers. Like Canguilhem's history of science and like modernist literature, Foucault's archaeology displaced the human subject from the central role it played in the humanism dominant in our culture since Kant. He reflected on the historical and philosophical significance of his archaeological method in *The Archaeology of Knowledge* (1969).

Foucault recognized that archaeology provided no account of transitions from one system to another. Accordingly, he introduced a "genealogical" approach, which does not replace archaeology but goes beyond it to explain changes in systems of discourse by connecting them to changes in the non-discursive practices of social power structures. Foucault's genealogy admitted the standard economic, social, and political causes but, in a nonstandard, Nietzschean vein, refused any unified teleological explanatory scheme (e.g., Whig or Marxist histories). New systems of thought are seen as contingent products of many small, unrelated causes, not fulfillments of grand historical designs. Foucault's genealogical studies emphasize the essential connection of knowledge and power. Bodies of knowledge are not autonomous intellectual structures that happen to be employed as Baconian instruments of power. Rather, precisely as bodies of knowledge, they are tied (but not reducible) to systems of social control. This essential connection of power and knowledge reflects Foucault's later view that power is not merely repressive but a creative, if always dangerous, source of positive values.

Discipline and Punish (1975) showed how prisons constitute criminals as objects of disciplinary knowledge. The first volume of the *History of Sexuality* (1976) sketched a project for seeing how, through modern biological and psychological sciences of sexuality, individuals are controlled by their own knowledge as self-scrutinizing and self-forming subjects. The second volume was projected as a study of the origins of the modern notion of a subject in practices of Christian confession. Foucault wrote such a study (*The Confessions of the Flesh*) but did not publish it because he decided that a proper understanding of the Christian development required a comparison with ancient conceptions of the ethical self. This led to two volumes (1984) on Greek and Roman sexuality: *The Use of Pleasure* and *The Care of the Self*. These final writings make explicit the ethical project that in fact informs all of Foucault's work: the liberation of human beings from contingent conceptual constraints masked as unsurpassable a priori limits and the adumbration of alternative forms of existence.

foundationalism, the view that knowledge and epistemic (knowledge-relevant) justification have a two-tiered structure: some instances of knowledge and justification are non-inferential, or foundational; and all other instances thereof are inferential, or non-foundational, in that they derive ultimately from foundational knowledge or justification. This structural view originates in Aristotle's *Posterior Analytics* (at least regarding knowledge), receives an extreme formulation in Descartes's *Meditations*, and flourishes, with varying details, in the works of such twentieth-century philosophers as Russell, C. I. Lewis, and Chisholm. Versions of foundationalism differ on two main projects: (a) the precise explanation of the nature of non-inferential, or foundational, knowledge and justification, and (b) the specific explanation of how foundational knowledge and justification can be transmitted to non-foundational beliefs. Foundationalism allows for differences on these projects, since it is essentially a view about the *structure* of knowledge and epistemic justification.

The question whether knowledge has foundations is essentially the question whether the sort of justification pertinent to knowledge has a two-tiered structure. Some philosophers have construed the former question as asking whether knowledge depends on beliefs that are certain in some sense (e.g., indubitable or infallible). This construal bears, however, on only one species of foundationalism: *radical* foundationalism. Such foundationalism, represented primarily by Descartes, requires that foundational beliefs be certain and able to guarantee the certainty of the non-foundational beliefs they support. Radical foundationalism is currently unpopular, for two main reasons. First, very few, if any, of our perceptual beliefs are certain (i.e., indubitable); and, second, those of our beliefs that might be candidates for certainty (e.g., the belief that I am thinking) lack sufficient substance to guarantee the certainty of our rich, highly inferential knowledge of the external world (e.g., our knowledge of physics, chemistry, and biology).

Contemporary foundationalists typically endorse *modest* (or moderate) foundationalism, the view that non-inferentially justified, foundational beliefs need not possess or provide certainty and need not deductively support justified non-foundational beliefs. Foundational beliefs (or statements) are often called *basic* beliefs (or statements), but the precise understanding of 'basic' here is controversial among foundationalists. Foundationalists agree, however, in their general understanding of non-inferentially justified, foundational beliefs as beliefs whose *justification* does not derive from other beliefs, although they leave open whether the *causal basis* of foundational beliefs includes other beliefs. (Epistemic justification comes in degrees, but for simplicity we can restrict discussion to justification sufficient for satisfaction of the justification condition for knowledge; we can also restrict discussion to what it takes for a belief to *have* justification, omitting issues of what it takes to *show* that a belief has it.)

Three prominent accounts of non-inferential justification are available to modest foundationalists: (a) self-justification, (b) justification by non-belief, non-propositional experiences, and (c) justification by a non-belief reliable origin of a belief. Proponents of self-justification (including, at one time, Ducasse and Chisholm) contend that foundational beliefs can justify themselves, with no evidential support elsewhere. Proponents of foundational justification by non-belief experiences shun literal self-justification; they hold, following C. I. Lewis, that foundational perceptual beliefs can be justified by non-belief sensory or perceptual experiences (e.g., seeming to see a dictionary) that make true, are best explained by, or otherwise support those beliefs (e.g., the belief that there is, or at least appears to be, a dictionary here). Proponents of foundational justification by reliable origins find the basis of non-inferential justification in belief-forming processes (e.g., perception, memory, introspection) that are truth-conducive, i.e. that tend to produce true rather than false beliefs. This view thus appeals to the reliability of a belief's non-belief origin, whereas the previous view appeals to the particular sensory or perceptual experiences that correspond to (e.g., make true or are best explained by) a foundational belief.

Despite disagreements over the basis of foundational justification, modest foundationalists typically agree that foundational justification is characterized by *defeasibility* – i.e., can be defeated, undermined, or overridden by a certain sort of expansion of one's evidence or justified beliefs. For instance, your belief that there is a blue dictionary before you could lose its justification (e.g., the justification from your current perceptual experiences) if you acquired new evidence that there is a blue light shining on the dictionary before you. Foundational justification, therefore, can vary over time if accompanied by relevant changes in one's perceptual evidence. It does not follow, however, that foundational justification positively depends, i.e. is based, on grounds for denying that there are defeaters. The relevant dependence can be regarded as negative in that there need only be an absence of genuine defeaters. Critics of foundationalism sometimes neglect that latter distinction regarding epistemic dependence.

The second big task for foundationalists is to explain how justification transmits from foundational beliefs to inferentially justified, non-foundational beliefs. Radical foundationalists insist, for such transmission, on entailment relations that guarantee the truth or the certainty of non-foundational beliefs. Modest foundationalists are more flexible, allowing for merely probabilistic inferential connections that transmit justification. For instance, a modest foundationalist can appeal to explanatory inferential connections, as when a foundational belief (e.g., I seem to feel wet) is best explained for a person by a particular physical-object belief (e.g., the belief that the air conditioner overhead is leaking on me). Various other forms of probabilistic inference are available to modest foundationalists; and nothing in principle requires that they restrict foundational beliefs to what one "seems" to sense or to perceive.

The traditional motivation for foundationalism comes largely from an eliminative regress argument, outlined originally (regarding knowledge) in Aristotle's *Posterior Analytics*. The argument, in shortest form, is that foundationalism is a correct account of the structure of justification since the alternative accounts all fail. *Inferential* justification is justification wherein one belief, *B1*, is justified on the basis of another belief, *B2*. How, if at all, is *B2*, the supporting belief, itself justified? Obviously, Aristotle suggests, we cannot have a circle here, where *B2* is justified by *B1;* nor can we allow the chain of support to extend endlessly, with no ultimate basis for justification. We cannot, moreover, allow *B2* to remain unjustified, lest it lack what it takes to support *B1*. If this is right, the structure of justification does not involve circles, endless regresses, or unjustified starter-beliefs. That is, this structure is evidently foundationalist. This is, in skeletal form, the regress argument for foundationalism. Given appropriate flesh, and due attention to skepticism about justification, this argument poses a serious challenge to non-foundationalist accounts of the structure of epistemic justification, such as epistemic coherentism. More significantly, foundationalism will then show forth as one of the most compelling accounts of the structure of knowledge and justification. This explains, at least in part, why foundationalism has been very prominent historically and is still widely held in contemporary epistemology.

Four Books, a group of Confucian texts, including the *Daxue* ("Great Learning"), *Zhongyong* ("Doctrine of the Mean"), *Lunyu* ("Analects"), and *Mengzi* ("Book of Mencius"), the latter two containing respectively the teachings of Confucius (sixth–fifth century B.C.) and Mencius (fourth century B.C.), and the former two being chapters from the *Liji* ("Book of Rites"). Zhu Xi (1130–1200) selected the texts as basic ones for Confucian education, and wrote influential commentaries on them. The texts served as the basis of civil service examinations from 1313 to 1905; as a result, they exerted great influence both on the development of Confucian thought and on Chinese life in general. Fourier, François-Marie-Charles (1772–1837), French social theorist and radical critic, often called a utopian socialist. His main works were *The Theory of Universal Unity* (1822) and *The New Industrial and Societal World* (1829). He argued that since each person has, not an integral soul, but only a partial one, personal integrity is possible only in unity with others. Fourier thought that all existing societies were antagonistic. (Following Edenism, he believed societies developed through stages of savagery, patriarchalism, barbarianism, and civilization.) He believed this antagonism could be transcended only in Harmony. It would be based on twelve kinds of passions. (Five were sensual, four affective, and three distributive; and these in turn encouraged the passion for unity.) The basic social unit would be a phalanx containing 300–400 families (about 1,600–1,800 people) of scientifically blended characters. As a place of production but also of maximal satisfaction of everyone's passions, Harmony should make labor attractive and pleasurable. The main occupations of its members should be gastronomy, opera, and horticulture. It should also establish a new world of love (a form of polygamy) where men and women have equal rights. Fourier believed that phalanxes would attract members of all other social systems, even the less civilized, and bring about this new world system.

Fourier's vision of cooperation (both in theory and in experimental practice) influenced anarchists, syndicalists, and the cooperationist movement. His radical social critique was important for the development of political and social thought in France, Europe, and North America.

Frankena, William K. (1908–94), American moral philosopher who wrote a series of influential articles and a text, *Ethics* (1963), which was translated into eight languages and remains in use. He taught at the University of Michigan (1937–78), where he and his colleagues C. L. Stevenson, a leading noncognitivist, and Richard Brandt, an important ethical naturalist, formed for many years one of the most formidable faculties in moral philosophy in the world. Frankena was known for analytical rigor and sharp insight, qualities already evident in his first essay, "The Naturalistic Fallacy" (1939), which refuted Moore's influential claim that ethical naturalism (or any other reductionist ethical theory) could be convicted of logical error. At best, Frankena showed, reductionists could be said to conflate or misidentify ethical properties with properties of some other kind. Even put this way, such assertions were question-begging, Frankena argued. Where Moore claimed to see properties of two different kinds, naturalists and other reductionists claimed to be able to see only one.

Many of Frankena's most important papers concerned similarly fundamental issues about value and normative judgment. "Obligation and Motivation in Recent Moral Philosophy" (1958), e.g., is a classic treatment of the debate between internalism, on which motivation is essential to obligation or to the belief or perception that one is obligated, and externalism, on which motivation is only contingently related to these. In addition to metaethics, Frankena's published works ranged broadly over normative ethical theory, virtue ethics, moral psychology, religious ethics, moral education, and philosophy of education. Although relatively few of his works were devoted exclusively to the area, Frankena was also known as the preeminent historian of ethics of his day. More usually, Frankena used the history of ethics as a framework in which to discuss issues of perennial interest.

It was, however, for *Ethics*, one of the most widely used and frequently cited philosophical ethics textbooks of the twentieth century, that Frankena was perhaps best known. *Ethics* continues to provide an unparalleled introduction to the subject, as useful in a first undergraduate course as it is to graduate students and professional philosophers looking for perspicuous ways to frame issues and categorize alternative solutions. For example, when in the 1970s philosophers came to systematically investigate normative ethical theories, it was Frankena's distinction in

Ethics between deontological and teleological theories to which they referred.

See also ETHICS, MORAL PSYCHOLOGY, MOTIVATIONAL INTERNALISM, NATURALISM. S.Dar.

Frankfurt, Harry (1929–), American philosopher and emeritus professor at Princeton University who investigates the import of higher-order attitudes regarding our motives to freedom of will and personhood. His early work on psychological sources of necessity in Descartes (especially *Demons, Dreamers and Madmen*, 1970) developed into a sustained examination in essays and books on freedom and the unavoidable.

Frankfurt likened the argument of "Alternate Possibilities and Moral Responsibility" (*Journal of Philosophy*, 1969) to piracy. Instead of earning compatibilism by specifying the sense in which responsible agents can do otherwise than they do, Frankfurt stole it with examples of agents responsible despite their inability to do so. In "Frankfurt cases," an agent performs a wrongful act on his own, while another unactivated force ensures he will act similarly should he hesitate. When the fail-safe mechanism remains unactivated, the agent is responsible for the act despite its unavoidability. Much has been written about such examples. But Frankfurt developed his compatibilism differently starting in "Freedom of Will and the Concept of a Person" (*Journal of Philosophy*, 1971), which argued that freedom of will consists in the power to be moved by a desire one wants to be moved by. The capacity to care which desire is effective distinguishes persons from "wantons," whose conduct is determined by their desires' strength. Later papers, included in *The Importance of What We Care About* (1988) and *Necessity, Volition and Love* (1999), refined the early account of "identification" with effective desires.

Agents sometimes identify with desires because neither they nor the higher-order attitudes favoring them can be shed. In essays and in *Reasons of Love* (2004) Frankfurt presented love, such as a parent's for a child, as involving such identification and as a source of demands essential to a person's life and immune to norms of reason. A commitment to the truth, however, is easily shed, a fact explored in *On Bullshit* (1986, 2005), which decries indifference to the truth (2005) and was a surprise best seller. Its success led to many media appearances and a related book, *On Truth* (2006). G.Y.

Frankfurt cases, cases designed by Harry Frankfurt as counterexamples to the thesis that one is morally responsible for a decision one made only if one could have decided otherwise. In his best-known case, a mind-reading agent (Black) with special control powers will cause another agent, Jones, to decide to *A* unless he sees that Jones will decide on his own to *A*. As it happens, Jones decides on his own to *A;* Black does not interfere. But, we are told, Jones could not have done otherwise than decide to *A;* if he had not decided on his own to *A*, Black would have caused him to decide to *A*. Because Black does not interfere and Jones is left to his own devices, it may seem that Jones's alleged inability to do otherwise than decide to *A* does not preclude his being morally responsible for deciding to *A*. Controversy concerning this case has led to modified Frankfurt cases of various kinds and to controversy. **See also** FREE WILL PROBLEM.

A.R.M.

Frankfurt School, a group of philosophers, cultural critics, and social scientists associated with the Institute for Social Research, which was founded in Frankfurt in 1929. Its prominent members included, among others, the philosophers Horkheimer, Adorno, and Marcuse, as well as the psychoanalyst Erich Fromm (1900–80) and the literary critic Walter Benjamin (1892–1940). Habermas is the leading representative of its second generation. The Frankfurt School is less known for particular theories or doctrines than for its program of a "critical theory of society." Critical theory represents a sophisticated effort to continue Marx's transformation of moral philosophy into social and political critique, while rejecting orthodox Marxism as a dogma. Critical theory is primarily a way of doing philosophy, integrating the normative aspects of philosophical reflection with the explanatory achievements of the social sciences. The ultimate goal of its program is to link theory and practice, to provide insight, and to empower subjects to change their oppressive circumstances and achieve human emancipation, a rational society that satisfies human needs and powers.

The first generation of the Frankfurt School went through three phases of development. The first, lasting from the beginning of the Institute until the end of the 1930s, can be called "interdisciplinary historical materialism" and is best represented in Horkheimer's programmatic writings. Horkheimer argued that a revised version of historical materialism could organize the results of social research and give it a critical perspective. The second, "critical theory" phase saw the abandonment of Marxism for a more generalized notion of critique. However, with the near victory of the Nazis in the early 1940s, Horkheimer and Adorno entered the third phase of the School, "the critique of instrumental reason." In their *Dialectic of Enlightenment* (1941) as well as in Marcuse's *One-Dimensional Man* (1964), the process of instrumentally dominating nature leads to dehumanization and the domination of human beings. In their writings after World War II, Adorno and Horkheimer became increasingly pessimistic, seeing around them a "totally administered society" and a manipulated, commodity culture.

Horkheimer's most important essays are from the first phase and focus on the relation of philosophy and social science. Besides providing a clear definition and program for critical social science, he proposes that the normative orientation of philosophy be combined with the empirical research in the social sciences. This metaphilosophical orientation distinguishes a "critical," as opposed to "traditional," theory. For example, such a program demands rethinking the relation of epistemology to the sociology of science. A critical theory seeks to show how the norm of truth is historical and practical, without falling into the skepticism or relativism of traditional sociologies of knowledge such as Mannheim's.

Adorno's major writings belong primarily to the second and third phases of the development of the Frankfurt School. As the possibilities for criticism appeared to him increasingly narrow, Adorno sought to discover them in aesthetic experience and the mimetic relation to nature. His approach was motivated by his view that modern society is a "false totality." His diagnosis of the causes traced this trend back to the spread of a one-sided, instrumental reason, based on the domination of nature and other human beings. For this reason, he sought a non-instrumental and non-dominating relation to nature and to others, and found it in diverse and fragmentary experiences. Primarily, it is art that preserves this possibility in contemporary society, since in art there is a possibility of mimesis, or the "non-identical" relation to the object. Adorno's influential attempt to avoid "the logic of identity" gives his posthumous *Aesthetic Theory* (1970) and other later works a paradoxical character.

It was in reaction to the third phase that the second generation of the Frankfurt School recast the idea of a critical theory. Habermas argued for a new emphasis on normative foundations as well as a return to an interdisciplinary research program in the social sciences. After first developing such a foundation in a theory of cognitive interests (technical, practical, and emancipatory), Habermas turned to a theory of the unavoidable presuppositions of communicative action and an ethics of discourse. The potential for emancipatory change lies in communicative, or discursive, rationality and practices that embody it, such as the democratic public sphere. Habermas's analysis of communication seeks to provide norms for non-dominating relations to others and a broader notion of reason.

free exercise, unimpeded religious activity or expression of religion, especially of religious convictions or attitudes (within certain limits, such as those corresponding to the moral rights of others). In the First Amendment of the U.S. Constitution, Congress is forbidden to make laws "prohibiting the free exercise" of religion. As with the other First Amendment freedoms, the Supreme Court takes the clause to apply to all levels of government – federal, state, and local. The free exercise clause identifies the right to adopt and (within certain limits) practice any religion. Philosophical questions arise chiefly where religious exercise involves overt behavior. The state may, for instance, forbid religiously sanctioned human sacrifice without violating free exercise rights. But there are more difficult cases. The Court continues to revise its understanding of when government may regulate religious behavior. In *Reynolds v. United States* (1878), the Court applied a "rational basis" standard for upholding the prosecution of a Mormon man under a federal anti-bigamy law. In *Sherbert v. Vermer* (1963), it adopted a "compelling interest" criterion in ruling that a Seventh Day Adventist was entitled to unemployment benefits despite refusing employment requiring working on Saturdays. But not all of the Court's First

Amendment decisions concern any particular religion: in *Employment Division v. Smith* (1990), it adopted a standard requiring only that a law constraining religious practice apply to all religions rather than any specific religion. **See also** ESTABLISHMENT, NEUTRALITY, POLITICAL PHILOSOPHY, RAWLS. free logic, a system of quantification theory, with or without identity, that allows for non-denoting singular terms. In classical quantification theory, all singular terms (free variables and individual constants) are assigned a denotation in all models. But this condition appears counterintuitive when such systems are applied to natural language, where many singular terms seem to be non-denoting ('Pegasus', 'Sherlock Holmes', etc.). Various solutions of this problem have been proposed, ranging from Frege's *chosen object theory* (assign an arbitrary denotation to each non-denoting singular term) to Russell's *description theory* (deny singular term status to most expressions used as such in natural language, and eliminate them from the "logical form" of that language) to a weakening of the quantifiers' "existential import," which allows for denotations to be possible, but not necessarily actual, objects. All these solutions preserve the structure of classical quantification theory and make adjustments at the level of application.

Free logic is a more radical solution: it allows for legitimate singular terms to be denotationless, maintains the quantifiers' existential import, but modifies both the proof theory and the semantics of first-order logic. Within proof theory, the main modification consists of eliminating the rule of existential generalization, which allows one to infer 'There exists a flying horse' from 'Pegasus is a flying horse'. Within semantics, the main problem is giving truth conditions for sentences containing non-denoting singular terms, and there are various ways of accomplishing this. *Conventional* semantics assigns truth-values to atomic sentences containing non-denoting singular terms by convention, and then determines the truth-values of complex sentences as usual. *Outer domain* semantics divides the domain of interpretation into an inner and an outer part, using the inner part as the range of quantifiers and the outer part to provide for "denotations" for non-denoting singular terms (which are then not literally denotation-less, but rather left without an *existing* denotation). *Supervaluational* semantics, when considering a sentence *A*, assigns all possible combinations of truth-values to the atomic components of *A* containing non-denoting singular terms, evaluates *A* on the basis of each of those combinations, and then assigns to *A* the logical product of all such evaluations. (Thus both 'Pegasus flies' and 'Pegasus does not fly' turn out to be truth-valueless, but 'Pegasus flies or Pegasus does not fly' turns out to be true since, whatever truth-value is assigned to its atomic component 'Pegasus flies', the truth-value for the whole sentence is true.) A free logic is *inclusive* if it allows for the possibility that the range of quantifiers be empty (that there exists nothing at all); it is *exclusive* otherwise.

free rider, a person who benefits from a social arrangement without bearing an appropriate share of the burdens of maintaining that arrangement, e.g. one who benefits from government services without paying taxes that support them. The arrangements from which a free rider benefits may be either formal or informal. A cooperative arrangement that permits free riders is likely to be unstable; parties to the arrangement are unlikely to continue to bear the burdens of maintaining it if others are able to benefit without doing their part. As a result, it is common for cooperative arrangements to include mechanisms to discourage free riders, e.g. legal punishment, or in cases of informal conventions the mere disapproval of one's peers. It is a matter of some controversy as to whether it is always morally wrong to benefit from an arrangement without contributing to its maintenance. **See also** JUSTICE, SOCIAL CHOICE THEORY, UTILITARIANISM. free will defense. See PHILOSOPHY OF RELIGION.

free will problem, the problem of the nature of free agency and its relation to the origins and conditions of responsible behavior. For those who contrast 'free' with 'determined', a central question is whether humans are free in what they do or determined by external events beyond their control. A related concern is whether responsibility for an action requires that the agent, the act, or the relevant decision be free. These, in turn, direct attention to action, motivation, deliberation, choice, and intention, and to the sense, if any, in which our actions are under our control. Use of 'free will' is a matter of traditional nomenclature; it is debated whether freedom is properly ascribed to the *will* or the agent, or to actions, choices, deliberations, etc.

Controversy over conditions of responsible behavior forms the predominant historical and conceptual background of the free will problem. Most who ascribe moral responsibility acknowledge some sense in which agents must be free in acting as they do; we are not responsible for what we were forced to do or unable to avoid no matter how hard we tried. But there are differing accounts of moral responsibility and disagreements about the nature and extent of *practical freedom*. Accordingly, the free will problem centers on these questions: Does moral responsibility require practical freedom? If so, what sort? Is practical freedom consistent with the antecedent determination of actions, thoughts, and character? There is vivid debate about this last question. Consider a woman deliberating about whom to vote for. From her first-person perspective, she feels free to vote for any candidate and is convinced that the selection is up to her. But, viewing her eventual behavior as a segment of larger natural and historical processes, many would argue that underlying causes determine her choice. Deciding whether the voter is free depends on the precise meanings associated with words and phrases like ‘free’, ‘determine’, and ‘up to her’.

One thing (event, situation) *determines* another if the latter is a consequence of it; e.g., the voter’s hand movements are determined by her intention; and, as usually understood, determinism is the thesis that whatever happens is causally necessitated by antecedent events and circumstances. So construed, determinism apparently implies that at any time the future is fixed, with no possibility of alternative development. Logical versions of determinism declare each future event to be determined by what is already true, specifically by the truth that it will occur then. Certain theological variants accept the *predestination* of all circumstances and events by a divine being who knows in advance that they will obtain.

Two elements are common to most interpretations of ‘free’. First, freedom requires an absence of certain kinds of determination, and second, one acts and chooses freely only if these endeavors are, properly speaking, one’s *own*. From here, accounts diverge. Some consider *freedom (liberty) of indifference* or the contingency of alternative actions critical, so that for the deliberating voter, each choice is an open alternative: possible but not yet necessitated. Indifference is also construed as motivational equilibrium, a condition some find essential to the idea that a free choice must be rational. Others focus on *freedom (liberty) of spontaneity*, where the voter is free if she would vote as she chooses or desires, a reading that reflects the popular equation of freedom with “doing what you want.” Associated with both analyses is a third by which we act freely if we exercise our *control*, implying not only responsiveness to intent, but abilities both to act and to refrain from acting. A fourth view identifies freedom with *autonomy*, the voter being autonomous: self-determined, e.g., by her character, deeper self, higher values, or informed reason. These conceptions are compatible, and many accounts of practical freedom include elements of each.

Determinism poses problems if practical freedom requires contingency (alternative possible actions). *Incompatibilism* maintains that determinism precludes freedom, though incompatibilists differ as to whether everything *is* determined. Those who accept determinism thereby endorse *hard determinism* (associated with eighteenth-century thinkers like d’Holbach and, more recently, certain behaviorists), on which freedom is an illusion since behavior is brought about by environmental and genetic factors. Some hard determinists also deny the existence of moral responsibility. At the opposite extreme, (metaphysical) *libertarianism* asserts that people are free and responsible and, *a fortiori*, that the past does not determine a unique future, a position some find enhanced by developments in quantum physics. Among adherents of this sort of incompatibilism are those who advocate a freedom of indifference by describing responsible choices as those that are undetermined by antecedent circumstances (Epicureans). To rebut the charge that choices, so construed, are random and not really one’s “own,” some suggest that several elements, including an agent’s reasons, delimit the range of possibilities and influence choices without necessitating them (Leibniz, Robert Kane). Libertarians who espouse agency causation, on the other hand, blend contingency with autonomy in characterizing a free choice as one that is determined by the agent, who in turn is not caused to make it (Carneades, Thomas Reid).

Unwilling to abandon practical freedom or to view a lack of determination as either necessary or desirable for responsibility, many philosophers take practical freedom and responsibility to be consistent with determinism, thereby endorsing *compatibilism*. Those who also accept determinism advocate what William James called *soft determinism*. Its supporters include some who identify freedom with autonomy (Stoics, Spinoza) and others who champion freedom of spontaneity (Hobbes, Locke, Hume). The latter speak of *liberty* as the power of doing or refraining from an action according to what one wills, so that by choosing otherwise one would have done otherwise. An agent fails to have liberty when constrained: either prevented from acting as one chooses or compelled to act in a manner contrary to what one wills. Extending this model, liberty is also diminished when one is caused to act in a way one would not otherwise prefer, either to avoid a greater danger (*coercion*) or because there is deliberate interference with the envisioning of alternatives (*manipulation*).

Compatibilists have shown considerable ingenuity in responding to criticisms that they have ignored freedom of choice or the need for open alternatives. Some apply the spontaneity, control, or autonomy models to decisions, so that the voter chooses freely if her decision accords with her desires, is under her control, or conforms to her higher values, deeper character, or informed reason. Others challenge the idea that responsibility requires alternative possibilities of action. In so-called *Frankfurt-style cases* agents act in accord with their desires and choices, but because of a counterfactual intervener – a mechanism that would have prevented doing any alternative action had they shown signs of acting differently – they could not have done otherwise. Frankfurt's intuition is that the agent is as responsible as he would have been even had there been no intervener and, thus, that responsible action does not require alternative possibilities. Critics have challenged the details of the Frankfurt-style cases by either denying the intuition or by granting that its appeal rests on the recognition of prior alternatives.

A different compatibilist strategy recognizes the need for open alternatives and employs versions of the indifference model in describing practical freedom. Choices are free if they are contingent relative to certain subsets of circumstances, e.g. those the agent is or claims to be cognizant of, with the openness of alternatives grounded in what one can do or choose "for all one knows."

Opponents of compatibilism charge that these refinements leave agents subject to external determination. Some advance the *manipulation argument:* even a covertly manipulated agent could satisfy compatibilist conditions on free agency, contrary to what seems plausible. Some compatibilists dispute the analogy; others argue that manipulation does not, per se, rule out responsibility. A more general objection to compatibilism is given by the *consequence argument* (so called by van Inwagen): if everything were determined by factors beyond one's control, then one's acts, choices, and character would also be beyond one's control, and consequently agents would never be free and hence never responsible. Such reasoning usually employs principles asserting the closure of the *practical modalities* (ability, control, avoidability, inevitability, etc.) under consequence relations. However, there is reason to suppose that the sort of control required by responsibility involves the agent's *sense* of what can be accomplished. Since cognitive states are typically not closed under consequence, the closure principles underlying the consequence argument are disputable.

Frege, Gottlob (1848–1925), German mathematician and philosopher, a founder of modern mathematical logic, an advocate of logicism, and a major source of twentieth-century analytic philosophy. He directly influenced Russell, Wittgenstein, and Carnap. Frege's distinction between the sense and the reference of linguistic expressions continues to be debated.

His first publication in logic was his strikingly original 1879 *Begriffsschrift* ("Concept Notation"). Here he devised a formal language whose central innovation is the quantifier-variable notation to express generality; he set forth in this language a version of second-order quantificational logic that he used to develop a logical definition of the ancestral of a relation. Frege invented his *Begriffsschrift* in order to circumvent drawbacks of the use of colloquial language to state proofs. Colloquial language is irregular, unperspicuous, and ambiguous in its expression of logical relationships. Moreover, logically crucial features of the content of statements may remain tacit and unspoken. It is thus impossible to determine exhaustively the premises on which the conclusion of any proof conducted within ordinary language depends. Frege's *Begriffsschrift* is to force the explicit statement of the logically relevant features of any assertion. Proofs in the system are limited to what can be obtained from a body of evidently true logical axioms by means of a small number of truth-preserving notational manipulations (inference rules). Here is the first hallmark of Frege's view of logic: his formulation of logic as a formal system and the ideal of explicitness and rigor that this presentation subserves.

Although the formal exactitude with which he formulates logic makes possible the metamathematical investigation of formalized theories, he showed almost no interest in metamathematical questions. He intended the *Begriffsschrift* to be used.

How, though, does Frege conceive the subject matter of logic? His orientation in logic is shaped by his *anti-psychologism*, his conviction that psychology has nothing to do with logic. He took his notation to be a full-fledged language in its own right. The logical axioms do not mention objects or properties whose investigation pertains to some special science; and Frege's quantifiers are unrestricted. Laws of logic are, as he says, the laws of truth, and these are the most general truths. He envisioned the supplementation of the logical vocabulary of the *Begriffsschrift* with the basic vocabulary of the special sciences. In this way the *Begriffsschrift* affords a framework for the completely rigorous deductive development of any science whatsoever. This resolutely non-psychological universalist view of logic as the most general science is the second hallmark of Frege's view of logic. This universalist view distinguishes his approach sharply from the coeval algebra of logic approach of Boole and Ernst Schröder. Wittgenstein, both in the *Tractatus Logico-Philosophicus* (1921) and in later writings, is very critical of Frege's universalist view. Logical positivism – most notably Carnap in *The Logical Syntax of Language* (1934) – rejected it as well. Frege's universalist view is also distinct from more contemporary views. With his view of quantifiers as intrinsically unrestricted, he saw little point in talking of varying interpretations of a language, believing that such talk is a confused way of getting at what is properly said by means of second-order generalizations. In particular, the semantical conception of logical consequences that becomes prominent in logic after Gödel's and Tarski's work is foreign to Frege.

Frege's work in logic was prompted by an inquiry into the ultimate foundation of arithmetic truths. He criticized J. S. Mill's empiricist attempt to ground knowledge of the arithmetic of the positive integers inductively in our manipulations of small collections of things. He also rejected crudely formalist views that take pure mathematics to be a sort of notational game. In contrast to these views and Kant's, he hoped to use his *Begriffsschrift* to define explicitly the basic notions of arithmetic in logical terms and to deduce the basic principles of arithmetic from logical axioms and these definitions. The explicitness and rigor of his formulation of logic will guarantee that there are no implicit extralogical premises on which the arithmetical conclusions depend. Such proofs, he believed, would show arithmetic to be analytic, not synthetic as Kant had claimed. However, Frege redefined 'analytic' to mean 'provable from logical laws' (in his rather un-Kantian sense of 'logic') and definitions.

Frege's strategy for these proofs rests on an analysis of the concept of cardinal number that he presented in his non-technical 1884 book, *The Foundations of Arithmetic*. Frege, attending to the use of numerals in statements like 'Mars has two moons', argued that it contains an assertion about a concept, that it asserts that there are exactly two things falling under the concept 'Martian moon'. He also noted that both numerals in these statements and those of pure arithmetic play the logical role of singular terms, his proper names. He concluded that numbers are objects, so that a definition of the concept of number must then specify what objects numbers are. He observed that

(1) the number of F = the number of G just in case there is a one-to-one correspondence between the objects that are F and those that are G.

The right-hand side of (1) is statable in purely logical terms. As Frege recognized, thanks to the definition of the ancestral of a relation, (1) suffices in the second-order setting of the *Begriffsschrift* for the derivation of elementary arithmetic. The vindication of his logicism requires, however, the logical definition of the expression 'the number of'. He sharply criticized the use in mathematics of any notion of set or collection that views a set as built up from its elements. However, he assumed that, corresponding to each concept, there is an object, the extension of the concept. He took the notion of an extension to be a logical one, although one to which the notion of a concept is prior. He adopted as a fundamental logical principle the ill-fated biconditional: the extension of F = the extension of G just in case every F is G, and vice versa. If this principle were valid, he could exploit the equivalence relation over concepts that figure in the right-hand side of (1) to identify the number of F with a certain extension and thus obtain (1) as a theorem. In *The Basic Laws of Arithmetic* (Vol. 1, 1893; Vol. 2, 1903) he formalized putative proofs of basic arithmetical laws within a modified version of the *Begriffsschrift* that included a generalization of the law of extensions. However, Frege's law of extensions, in the context of his logic, is inconsistent, leading to Russell's paradox, as Russell communicated to Frege in 1902. Frege's attempt to establish logicism was thus, on its own terms, unsuccessful.

In *Begriffsschrift* Frege rejected the thesis that every un-compound sentence is logically segmented into a subject and a predicate. Later, he said that his approach in logic was distinctive in starting not from the synthesis of concepts into judgments, but with the notion of truth and that to which this notion is applicable, the judgeable contents or thoughts that are expressed by statements. Although he said that truth is the goal of logic, he did not think that we have a grasp of the notion of truth that is independent of logic. He eschewed a correspondence theory of truth, embracing instead a redundancy view of the truth-predicate. For Frege, to call truth the goal of logic points toward logic's concern with inference, with the recognition-of-the-truth (judging) of one thought on the basis of the recognition-of-the-truth of another. This recognition-of-the-truth-of is not verbally expressed by a predicate, but rather in the assertive force with which a sentence is uttered. The starting point for logic is then reflection on elementary inference patterns that analyze thoughts and reveal a logical segmentation in language.

This starting point, and the fusion of logical and ontological categories it engenders, is arguably what Frege is pointing toward by his enigmatic *context principle* in *Foundations:* only in the context of a sentence does a word have a meaning. He views sentences as having a function-argument segmentation like that manifest in the terms of arithmetic, e.g. $(3 \times 4) + 2$. Truth-functional inference patterns, like *modus ponens*, isolate sentences as logical units in compound sentences. Leibniz's law – the substitution of one name for another in a sentence on the basis of an equation – isolates proper names. Proper names designate objects. Predicates, obtainable by removing proper names from sentences, designate concepts. The removal of a predicate from a sentence leaves a higher-level predicate that signifies a second-level concept under which first-level concepts fall. An example is the universal quantifier over objects: it designates a second-level concept under which a first-level concept falls, if every object falls under it. Frege takes each first-level concept to be determinately true or false of each object. Vague predicates, like 'is bald', thus fail to signify concepts. This requirement of concept determinacy is a product of Frege's construal of quantification over objects as intrinsically unrestricted. Thus, concept determinacy is simply a form of the law of the excluded middle: for any concept F and any object x, either x is F or x is not F.

Frege elaborates and modifies his basic logical ideas in three seminal papers from 1891 to 1892, "Function and Concept," "On Concept and Object," and "On Sense and Meaning." In "Function and Concept," Frege sharpens his conception of the function-argument structure of language. He introduces the two truth-values, the True and the False, and maintains that sentences are proper names of these objects. Concepts become functions that map objects to either the True or the False. The course-of-values of a function is introduced as a generalization of the notion of an extension. Generally, then, an object is anything that might be designated by a proper name. There is nothing more basic to be said by way of elucidating what an object is. Similarly, first-level functions are what are designated by the expressions that result from removing names from compound proper names. Frege calls functions *unsaturated* or incomplete, in contrast to objects, which are saturated. Proper names and function names are not intersubstitutable, so that the distinction between objects and functions is a type-theoretic, categorial distinction. No function is an object; no function name designates an object; there are no quantifiers that simultaneously generalize over both functions and concepts.

Just here Frege's exposition of his views, if not the views themselves, encounters a difficulty. In explaining his views, he uses proper names of the form 'the concept *F*' to talk about concepts; and in contrasting unsaturated functions with saturated objects, appears to generalize over both with a single quantifier. Benno Kerry, a contemporary of Frege, charged Frege's views with inconsistency. Since the phrase 'the concept *horse*' is a proper name, it must designate an object. On Frege's view, it follows that the concept 'horse' is not a concept, but an object, an apparent inconsistency. Frege responded to Kerry's criticism in "On Concept and Object." He embraced Kerry's paradox, denying that it represents a genuine inconsistency, while admitting that his remarks about the function-object distinction are, as the result of an unavoidable awkwardness of language, misleading. Frege maintained that the distinction between function and object is logically simple and so cannot be properly defined. His remarks on the distinction are informal hand waving designed to elucidate what is captured within the *Begriffsschrift* by the difference between proper names and function names together with their associated distinct quantifiers.

Frege's handling of the function-object distinction is a likely source for Wittgenstein's say-show distinction in the *Tractatus*.

At the beginning of "On Sense and Meaning," Frege distinguishes between the reference or meaning (*Bedeutung*) of a proper name and its sense (*Sinn*). He observes that the sentence 'The Morning Star is identical with the Morning Star' is a trivial instance of the principle of identity. In contrast, the sentence 'The Morning Star is identical with the Evening Star' expresses a substantive astronomical discovery. The two sentences thus differ in what Frege called their *cognitive value:* someone who understood both might believe the first and doubt the second. This difference cannot be explained in terms of any difference in reference between names in these sentences. Frege explained it in terms of a difference between the senses expressed by 'the Morning Star' and 'the Evening Star'. In posthumously published writings, he indicated that the sense-reference distinction extends to function names as well. In this distinction, Frege extends to names the notion of the judgeable content expressed by a sentence: the sense of a name is the contribution that the name makes to the thought expressed by sentences in which it occurs. Simultaneously, in classifying sentences as proper names of truth-values, he applies to sentences the notion of a name's referring to something. Frege's function-argument view of logical segmentation constrains his view of both the meaning and the sense of compound names: the substitution for any name occurring in a compound expression of a name with the same reference (sense) yields a new compound expression with the same reference (sense) as the original.
