ENSEMBLE

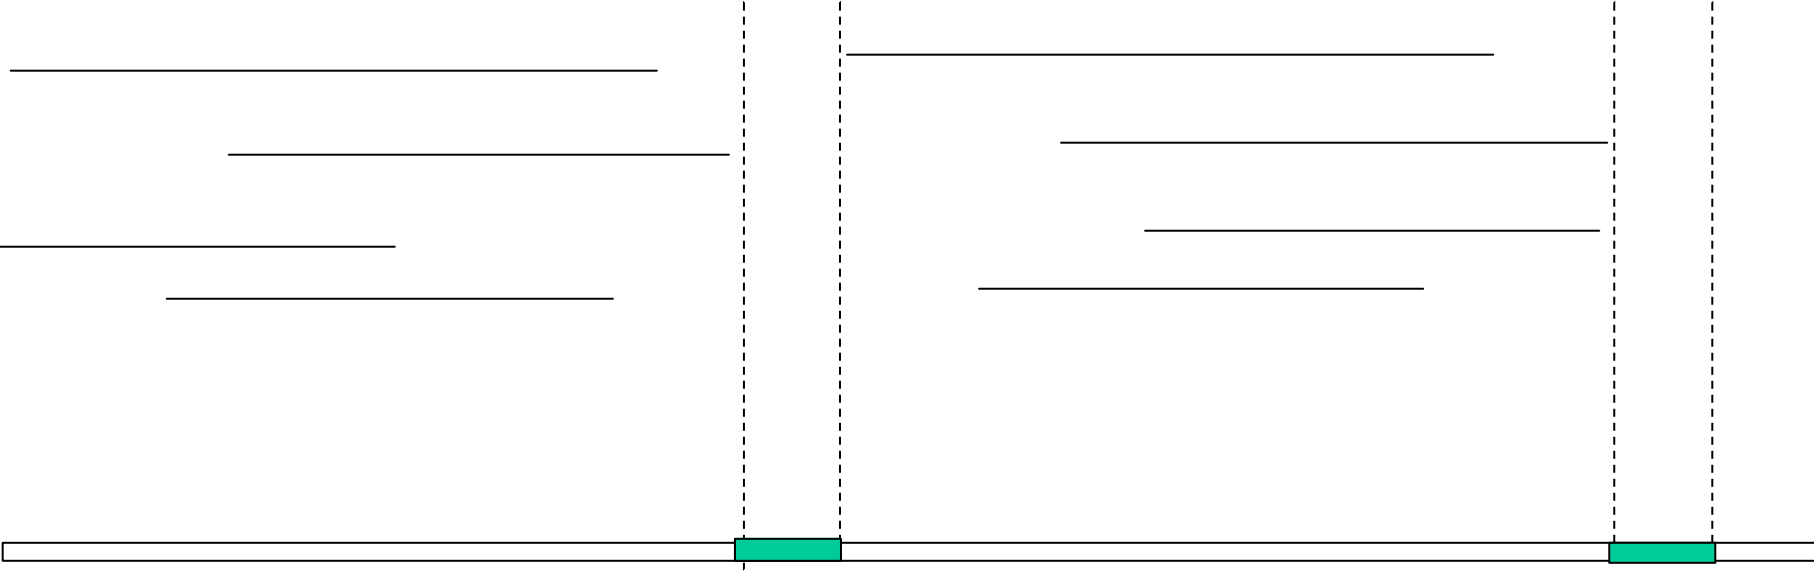

# Assembly:

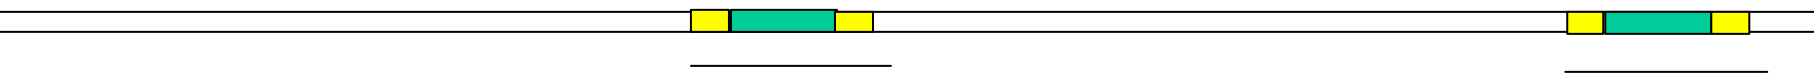

- Putting sequenced fragments of DNA into their correct chromosomal positions

# Contig

- Contiguous sequence of DNA created by assembling overlapping sequenced fragments of a chromosome (whether natural or artificial, as in BACs)

Recuperación de  
fragmentos vía PCR

2

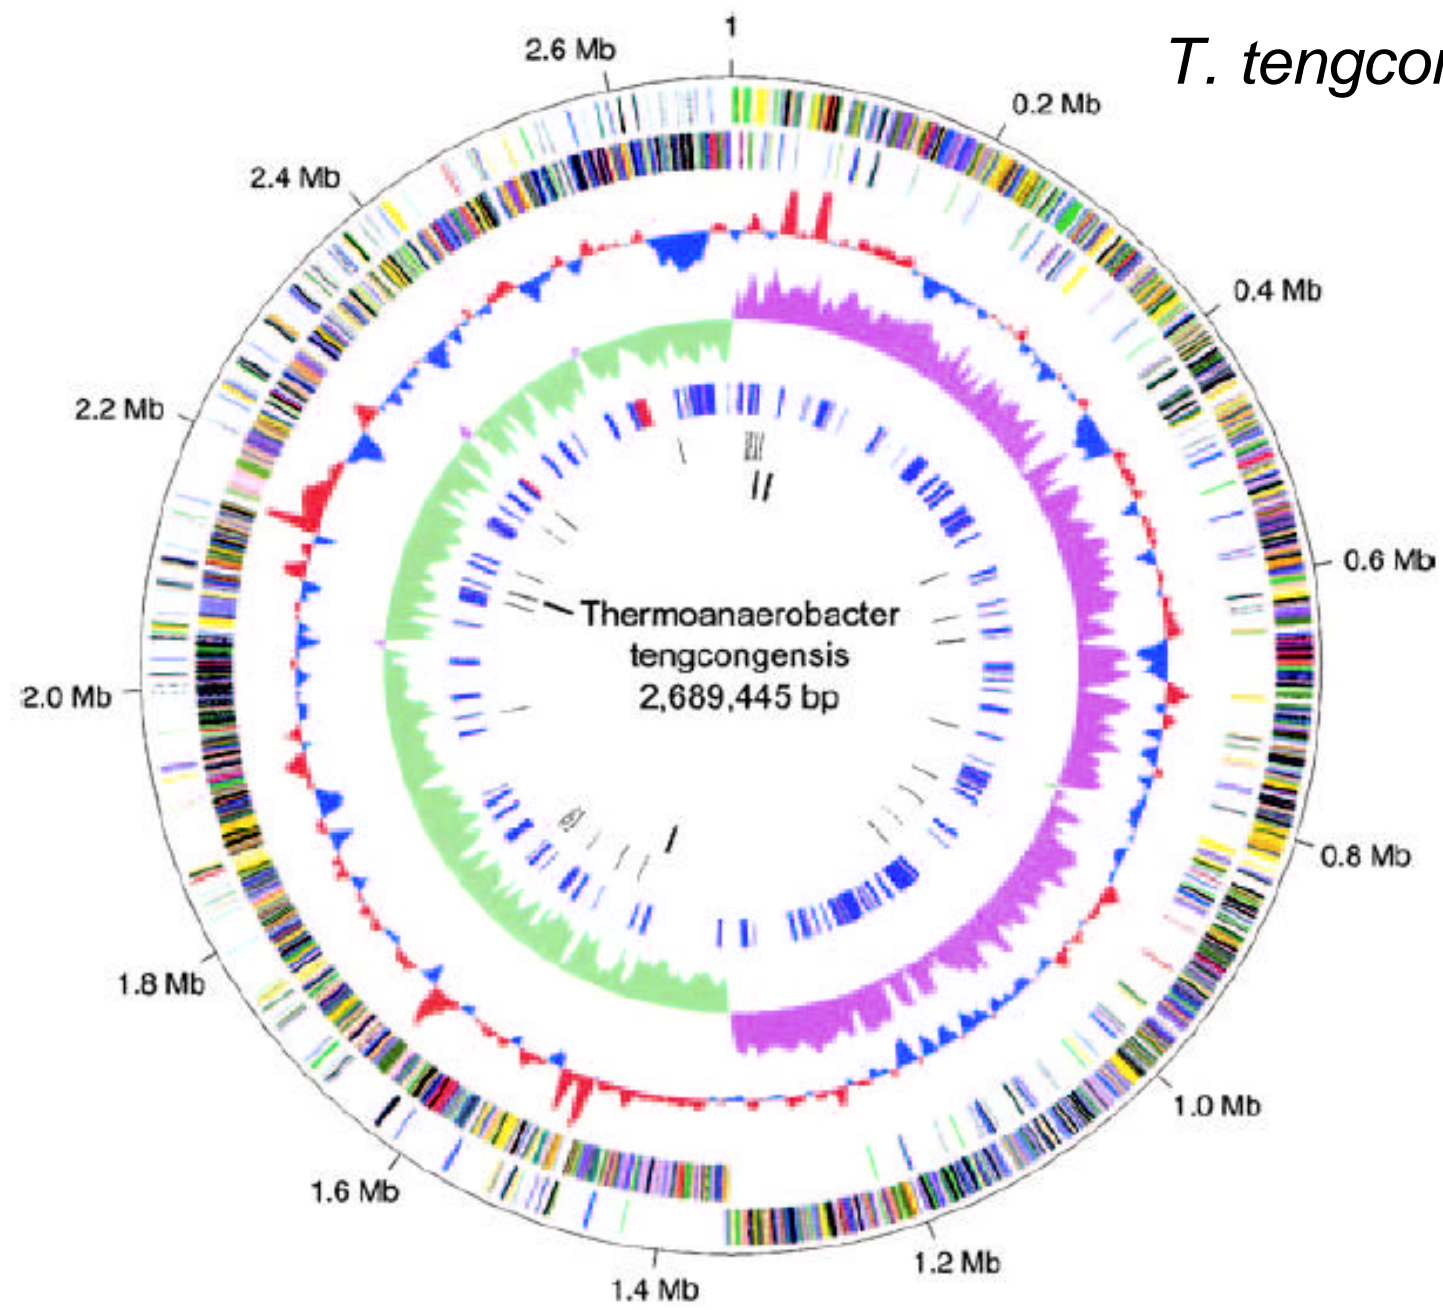

Repetición del protocolo de secuenciación con nuevos clones.

# The fragment assembly problem

- Aim: infer the target from the reads
- Difficulties –
  - Incomplete coverage. Leaves *contigs* separated by *gaps* of unknown size.
  - Sequencing errors. Rate increases with length of read. Less than some  $\epsilon$ .
  - Unknown orientation. Don't know whether to use read or its Watson-Crick complement.

*T. tengcongensis*

# Draft sequence

- Sequence with lower accuracy than a finished sequence; some segments are missing or in the wrong order or orientation

**Table 1.** General Features of the *Thermoanaerobacter tengcongensis* Genome

Genome size (bp)	2,689,445	
G+C content	37.6%	
Protein coding	87.1%	
Average CDS length (bp)	905	
Predicted CDS	2,588	
Homologous to	Known proteins	1494 (57.8%)
	Protein domains/motifs	270 (10.4%)
	Hypothetical proteins	301 (11.6%)
	No homology	523 (20.2%)
Stable RNAs	0.9%	
rRNA operons	4	
rRNAs	55	
Major repetitive elements		
Short noncoding repeats	0.5%	
Long coding repeats	8.6%	

CDS, coding sequences.

Origin of DNA replication:

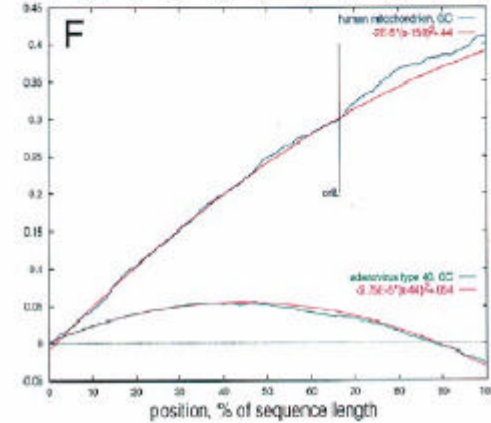

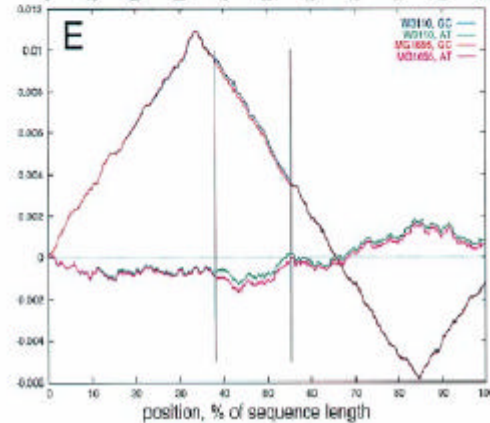

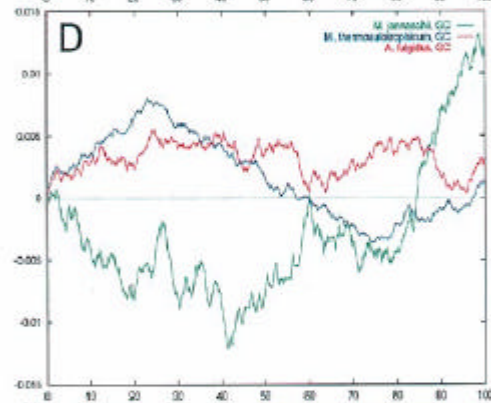

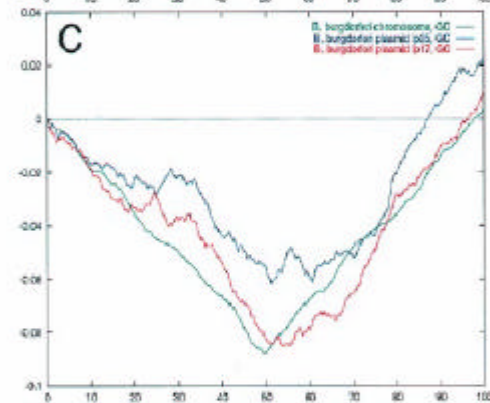

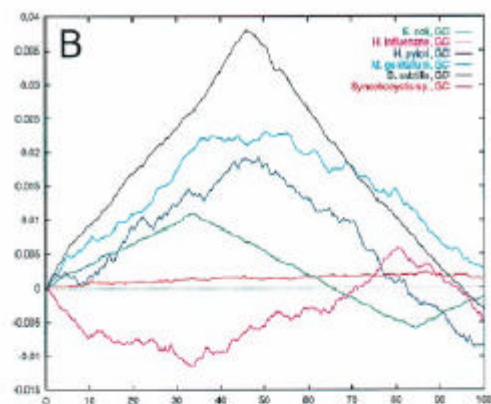

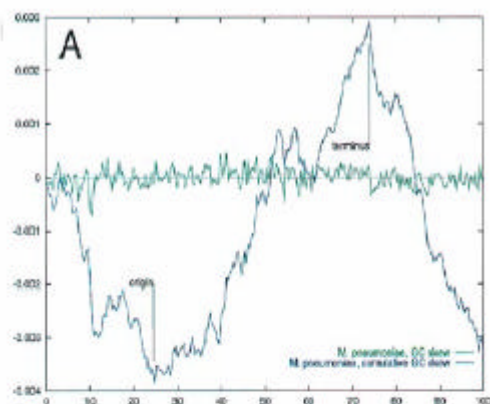

GC skew.

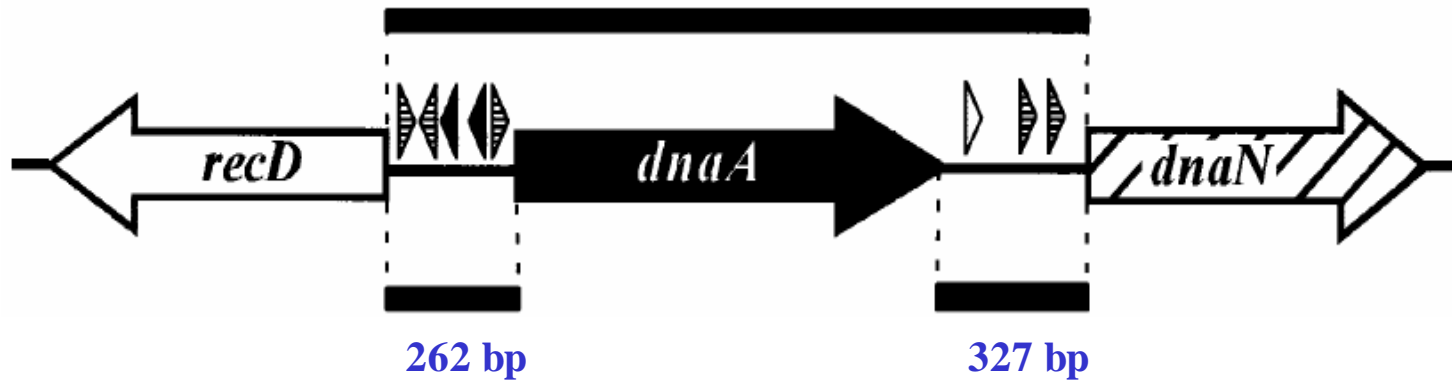

Protocol to find and verify the replicative origin (oriC) of the any bacterial chromosome:

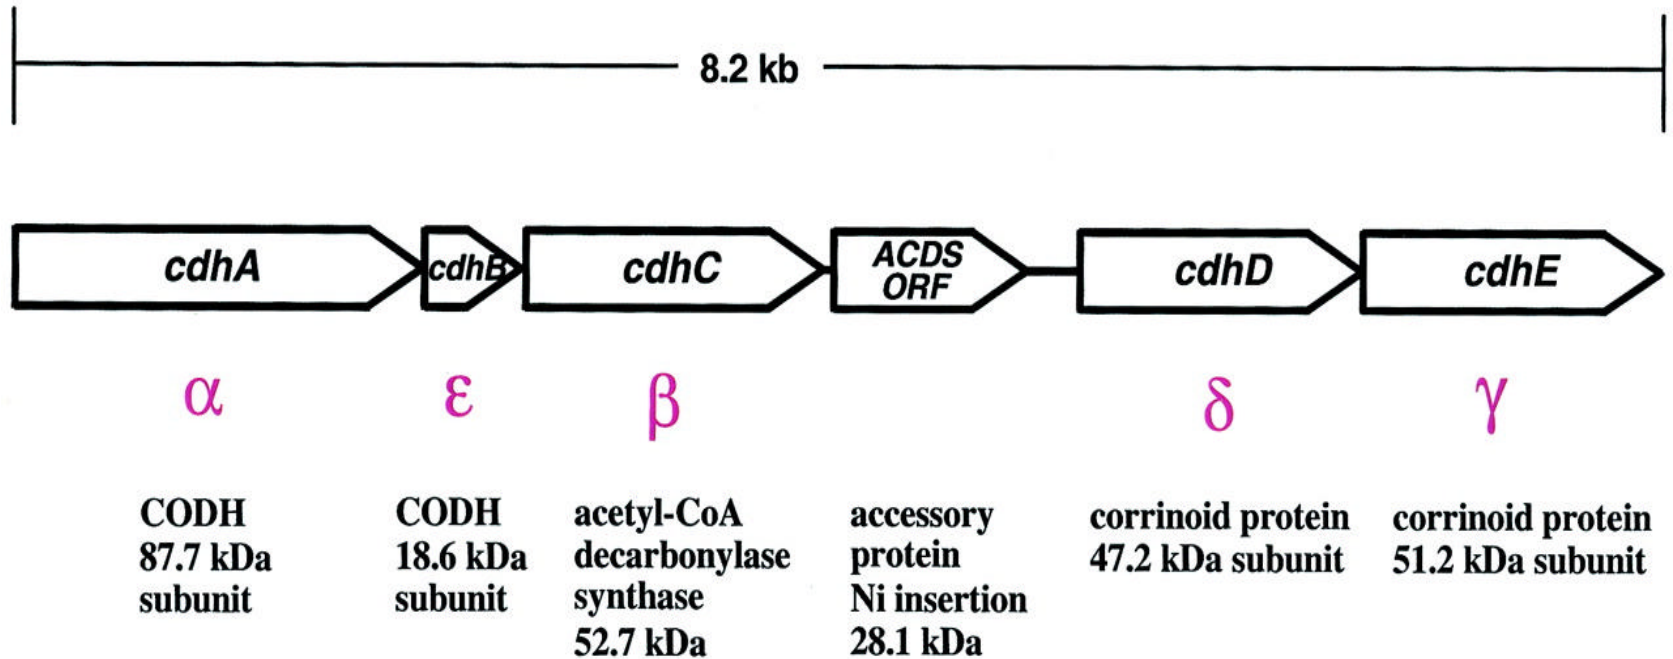

- 1) GC nucleotide skew  $[(G-C)/(G+C)]$  analysis.
- 2) Identification by similarity, in this case we evaluated the co-localisation of several genes found around the origin of others bacterias. Typically bacteria contain the genes *dnaA*, *dnaN*, *recF* and *gyrB*, however the *Bacillus subtilis* chromosome include only the genes *dnaA* and *dnaN* while *rpmH* and *recF* are not include (Kuroda et al., 2001. The Lancet, 357: 1225), in *E. coli* *dnaN* and *gyrB* are present, *dnaA* is located 600bp away from *dnaN* – *gyrB*, and *recF* gene is missing. (Zawilaket al., 2001. Nucleid Acids Research **29**:2251).
- 3) In addition, we need evaluate if the replication origins region, contain short AT rich sequences and named DnaA box characteristic of bacterial (in *E. coli* and in *H. Pylori* there are 5 DnaA box).

1.9 kbp

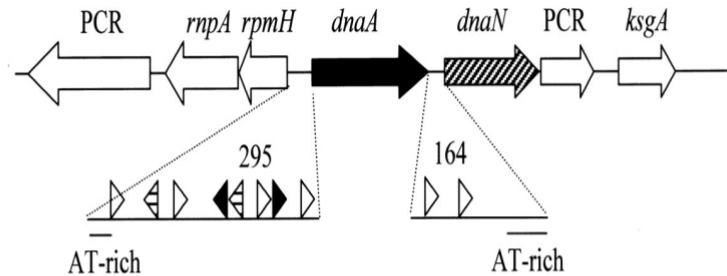

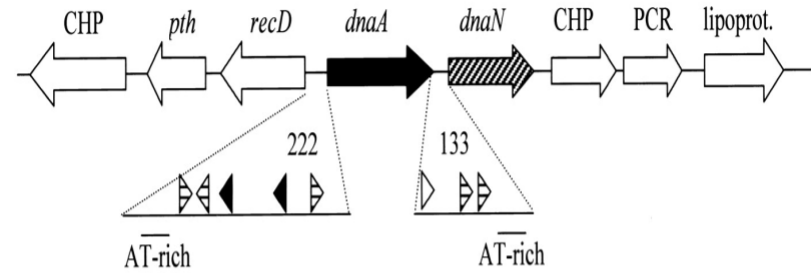

**Organization of the ACDS operon in *M. thermophila* TM-1.**

# Gene order and putative DnaA boxes within the oriC regions of mollicute genomes.

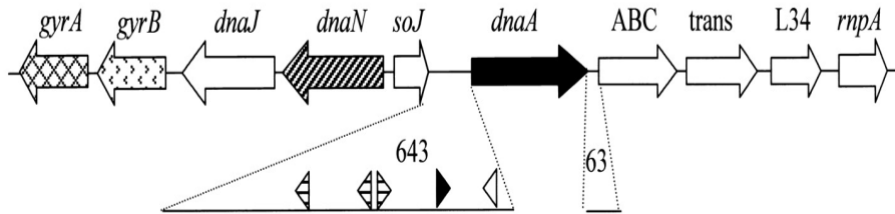

## *M. capricolum*

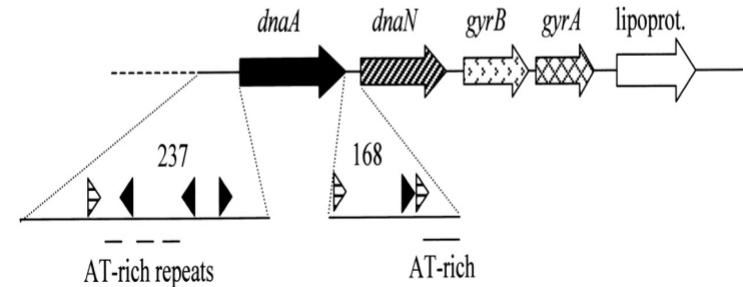

## *M. pulmonis*

## *M. genitalium*

## *S. citri*

Orientations of the genes are indicated by rows; intergenic regions flanking the *dnaA* genes are magnified with their lengths (in nucleotides) indicated. PCR, putative coding region; CHP, conserved hypothetical protein. Putative DnaA boxes are represented by headless arrows. A match with the consensus defined for mollicutes (TT(A/T)TC(C/A)ACA) is symbolized by the following: black, nine of nine; horizontal stripes, eight of nine; white, seven of nine. Caio et al., J. Bacteriology, 2002, **184**: 5426–5435

**Table I**

**Stoichiometry of DnaA, DnaB, and DnaC at the DnaA box hairpin**

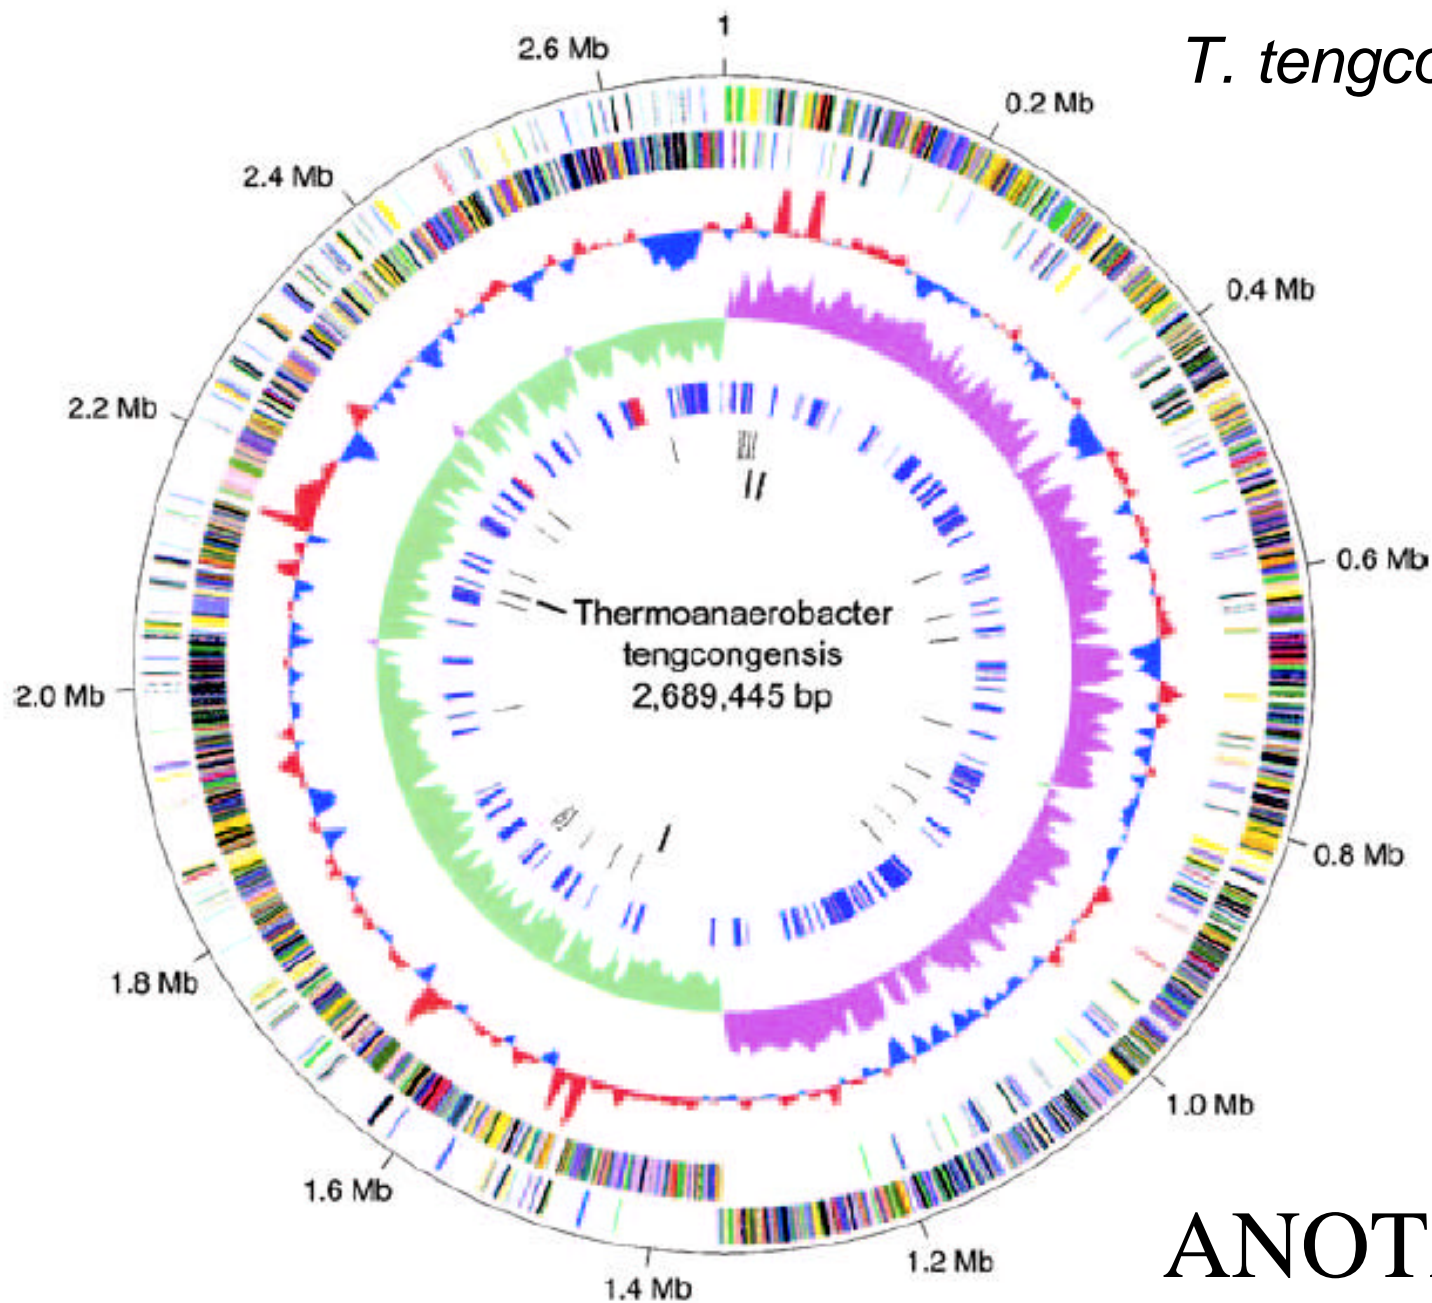

The results from replicate experiments under the indicated experimental conditions were averaged to calculate the S.D. for the stoichiometries of DnaA, DnaB, and DnaC protein bound to the ssDNA. The term  $n$  refers to the number of replicate experiments under a given condition.

Reaction conditions	DnaA	DnaB	DnaC	$n$
DnaA, DnaB, DnaC, and 0.1 mM ATP $\gamma$ S	$3.6 \pm 0.8$	$4.0 \pm 0.9$	$3.8 \pm 1.6$	3
DnaA, DnaB, DnaC, and 0.1 mM ATP	$2.3 \pm 0.5$	$4.2 \pm 0.8$	None detected	4
DnaA and 0.1 mM ATP $\gamma$ S	$3.9 \pm 1.9$			5
DnaA and 0.1 mM ATP	$2.6 \pm 1.0$			2

Primer termination  
dependent on  
the DnaB-DnaC complex

Primer termination  
dependent on DnaA,  
and enhanced by the  
DnaB-DnaC complex

Similar replication factors

### Figure 1

Evolutionary relationships between bacteria, archaea and eukaryotes takes into account the similarities between archaea replication, transcription and translation factors with eukaryotic factors. The report by Myllykallio *et al.* [1] shows that the archaea share chromosome organization and replication pattern with prokaryotes although they use many eukaryotic-like factors to duplicate their chromosomes.

---

**Figure 2**

A bi-directional replication fork: DNA replicated by lagging-strand synthesis on one side of the origin will be replicated by leading-strand synthesis on the other side. In bacteria, there is a switch in the strand bias of guanine content at the origin. Myllykallio *et al.* [1] measured the strand bias resulting from GGGT as illustrated.
