\end{aligned}$$

(b) Trigonométricos

- i. Como el intervalo es $[-1, 1]$, para aplicar los polinomios trigonométricos debemos transformar el intervalo $[-\pi, \pi]$ a $[-1, 1]$. Para esto se usa la transformación lineal $\frac{x}{\pi} = u$.
- ii. La base trigonométrica queda de la forma:
 $\phi_0(u) = \frac{1}{2}$
 $\phi_1(u) = \cos(\pi u)$
 $\phi_2(u) = \cos(2\pi u)$
 $\phi_3(u) = \sin(\pi u)$
- iii. Los coeficientes son:
 $a_0 = \int_{-1}^1 u \sin(\pi u) du = \frac{2}{\pi}$
 $a_1 = \int_{-1}^1 \cos(\pi u) [u \sin(\pi u)] du = -\frac{1}{2\pi}$
 $a_2 = \int_{-1}^1 \cos(2\pi u) [u \sin(\pi u)] du = -\frac{2}{3\pi}$
 $b_1 = \int_{-1}^1 \sin(\pi u) [u \sin(\pi u)] du = 0$
- iv. El polinomio resultante es:
 $S(u) = \frac{a_0}{2} + a_2 \cos(2\pi u) + a_1 \cos(\pi u) + b_1 \sin(\pi u)$
 $= \frac{\frac{2}{\pi}}{2} - \frac{2}{3\pi} \cos(2\pi u) - \frac{1}{2\pi} \cos(\pi u) + 0$
 $= \frac{1}{\pi} - \frac{1}{2\pi} \cos(\pi u) - \frac{2}{3\pi} \cos(2\pi u)$

&= \int_{-1}^1 (c_1^2 - 2x c_1 \sin \pi x + 2x^2 c_1 c_2 - 2x^3 c_2 \sin \pi x + x^4 c_2^2 + x^2 \sin^2 \pi x) dx \\
&= c_1^2 \int_{-1}^1 dx - 2c_1 \int_{-1}^1 x \sin \pi x dx + 2c_1 c_2 \int_{-1}^1 x^2 dx - 2c_2 \int_{-1}^1 x^3 \sin \pi x dx + c_2^2 \int_{-1}^1 x^4 dx + \int_{-1}^1 x^2 \sin^2 \pi x dx \\
&= 2c_1^2 - 2c_1 \frac{2}{\pi} + 2c_1 c_2 \frac{2}{3} - 2c_2 \left(\frac{2}{\pi} - \frac{12}{\pi^3} \right) + c_2^2 \frac{2}{5} + \left(\frac{1}{3} - \frac{1}{2\pi^2} \right)
\end{aligned}$$

Ahora, evaluando con $c_1 \simeq 0.248$, $c_2 \simeq 0.210$

$$E_L \simeq 7.2164763566785362844 \times 10^{-2}$$

ii. Trigonométrico

$$\begin{aligned}
E_T &= \int_{-1}^1 (f(x) - S(x))^2 dx = \int_{-1}^1 (x \sin(\pi x) - \frac{1}{\pi} + \frac{1}{2\pi} \cos(\pi x) + \frac{2}{3\pi} \cos(2\pi x))^2 dx \\
&= 2 \int_{-1}^1 \left(-\frac{1}{\pi} x \sin(\pi x) + \frac{1}{2\pi} \cos(\pi x) x \sin(\pi x) + \frac{2}{3\pi} \cos(2\pi x) x \sin(\pi x) - \frac{1}{2\pi^2} \cos(\pi x) - \frac{2}{3\pi^2} \cos(2\pi x) + \frac{1}{3\pi^2} \cos(\pi x) \cos(2\pi x) \right) \\
&\quad + \int_{-1}^1 x^2 \sin^2(\pi x) dx + \int_{-1}^1 \frac{1}{\pi^2} dx + \int_{-1}^1 \frac{1}{4\pi^2} \cos^2(\pi x) dx + \int_{-1}^1 \frac{4}{9\pi^2} \cos^2(2\pi x) dx \\
&= 2 \left(-\frac{2}{\pi^2} - \frac{1}{4\pi^2} - \frac{4}{9\pi^2} + 0 + 0 + 0 \right) + \left(\frac{1}{3} - \frac{1}{2\pi^2} \right) + \frac{2}{\pi^2} + \frac{1}{4\pi^2} + \frac{4}{9\pi^2} \\
&= \frac{1}{3} - \frac{115}{36\pi^2} \simeq 9.6684411425321189987 \times 10^{-3}
\end{aligned}$$

iii. Entonces, como $E_T < E_L$, eso implica que la aproximación por el polinomio trigonométrico tiene menor error, por lo que es mejor

(d) Observaciones:

- Muchas funciones las cuales se integraban eran impares, por lo que se podía poner que vale cero sin hacer cálculos
- Muchas integrales salen muchas veces, por lo que no era necesario repetir las mismas integrales si se anotaban ya una vez
- En la parte b), si se aplicaba la definición del método de los mínimos cuadrados se obtenía la forma de las constantes, y lo importante era conservar la ortogonalidad de la base trigonométrica en $[-1, 1]$.
