Hydrophilic "head group"

"Flickering clusters" of H$_2$O molecules in bulk phase

Highly ordered H$_2$O molecules form "cages" around the hydrophobic alkyl chains
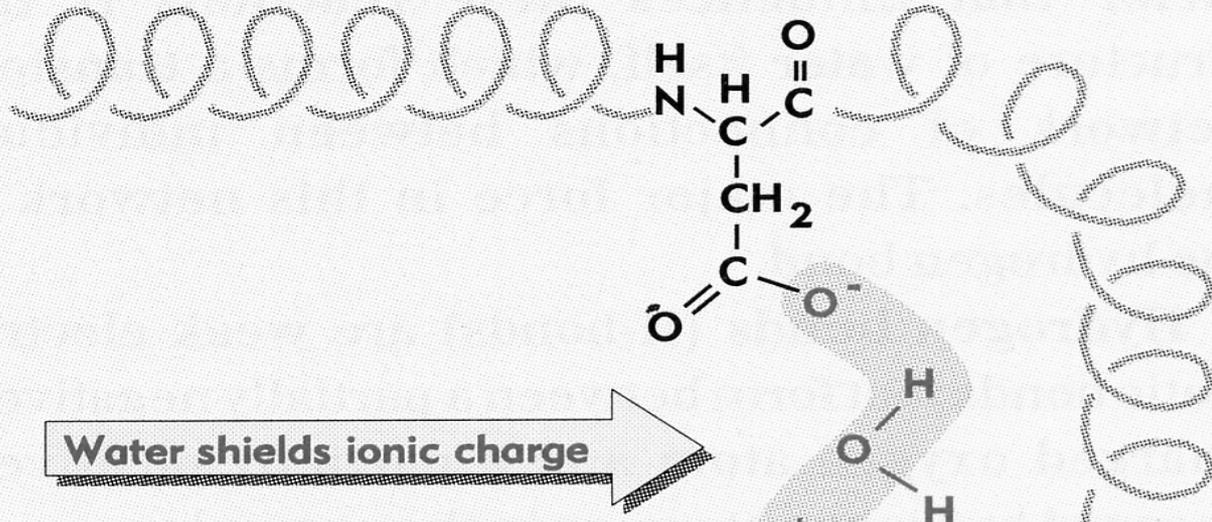

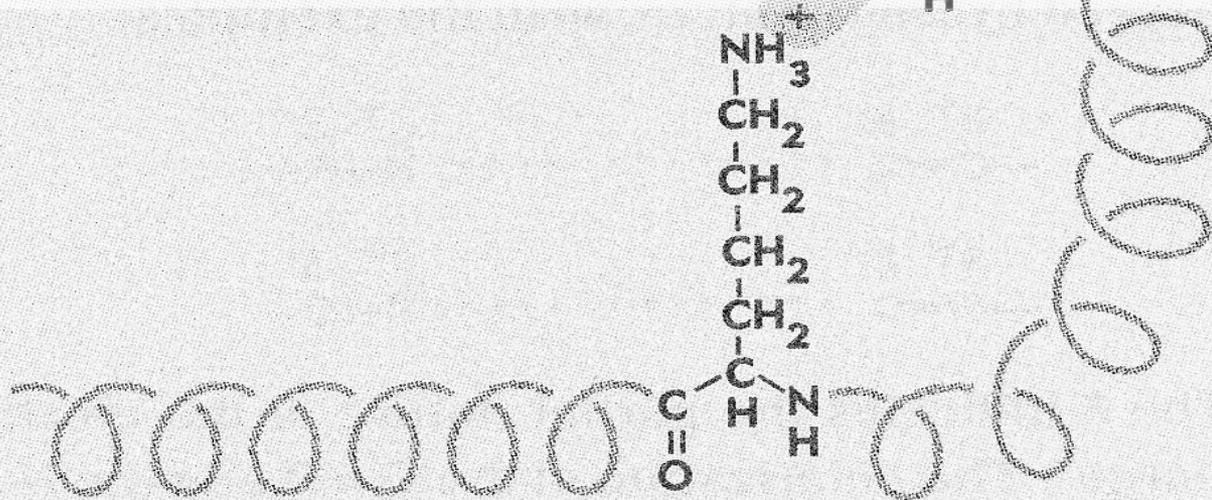

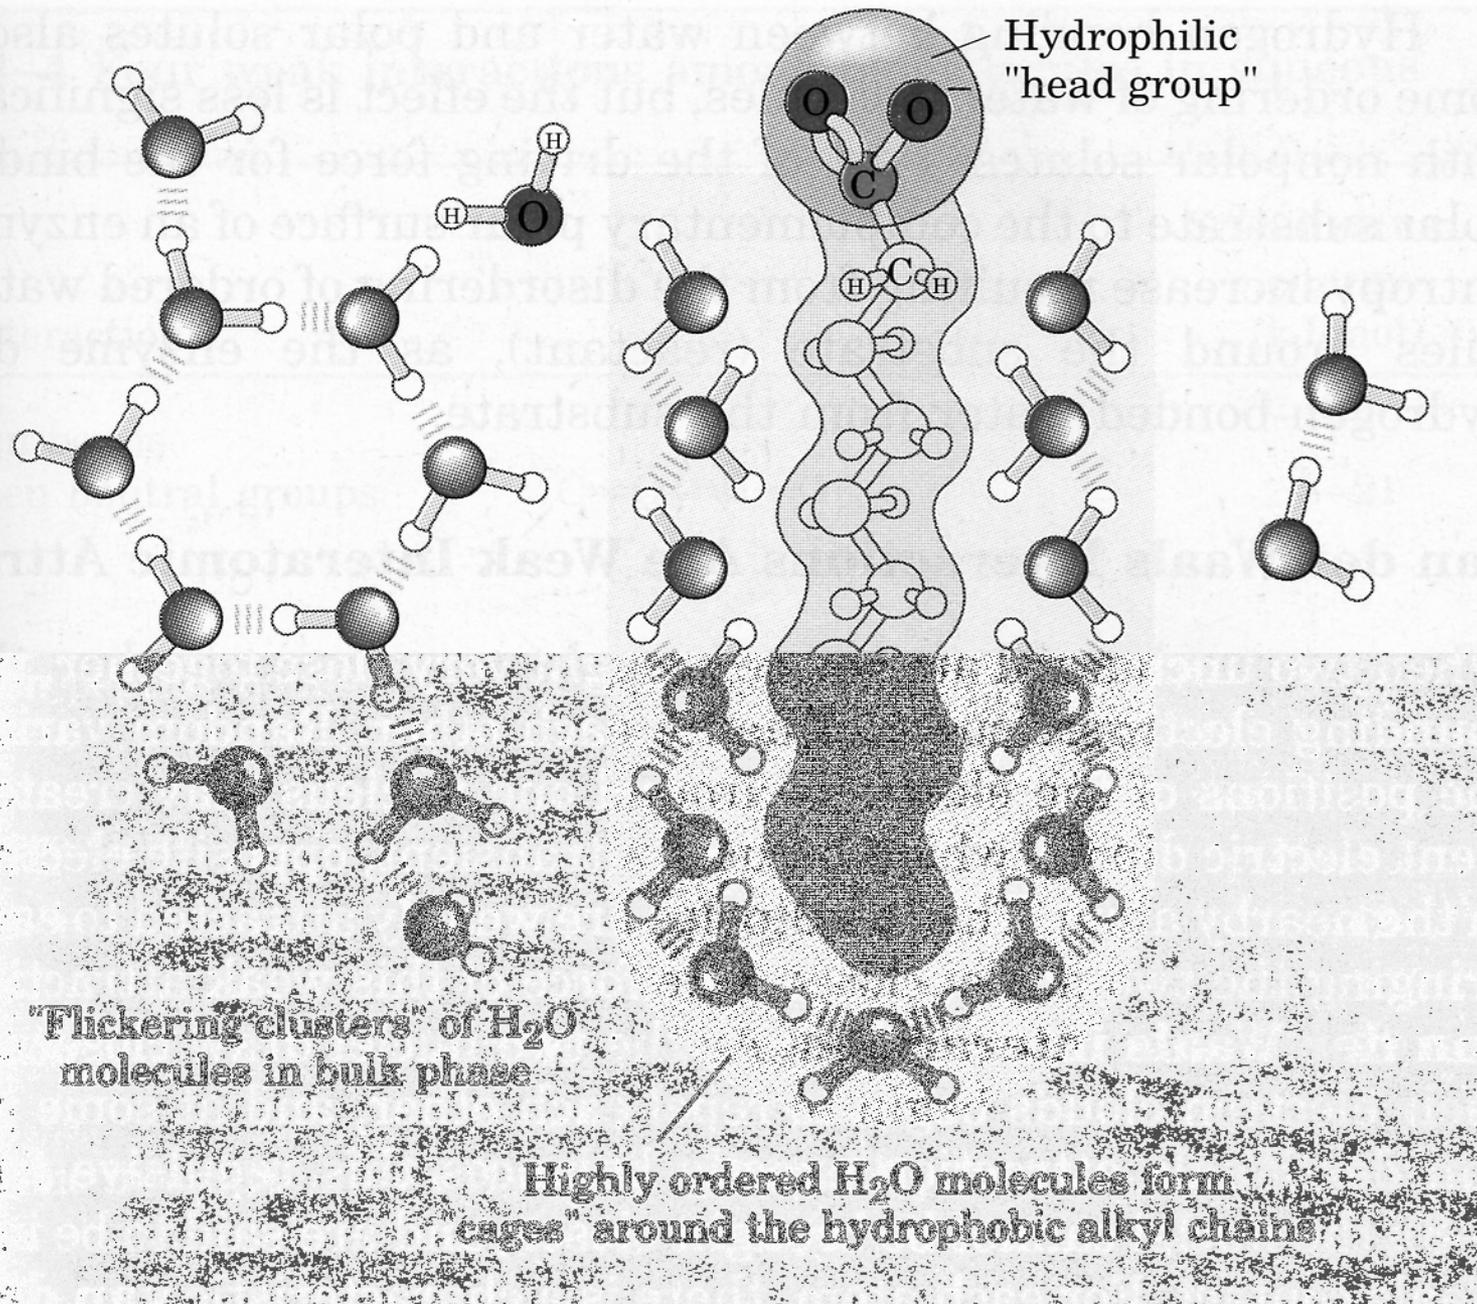

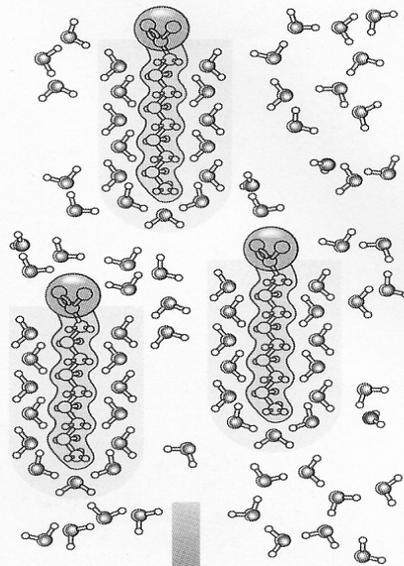

**Dispersion of lipids in H₂O**

Each lipid molecule forces surrounding H₂O molecules to become highly ordered.
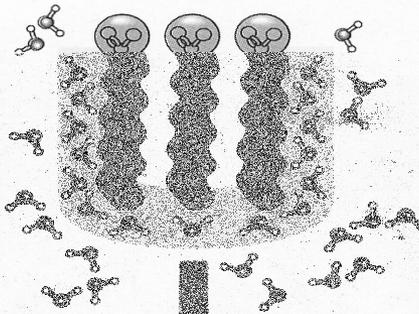

**Clusters of lipid molecules**

Only lipid portions at the edge of the cluster force the ordering of water. Fewer H₂O molecules are ordered, and entropy is increased.
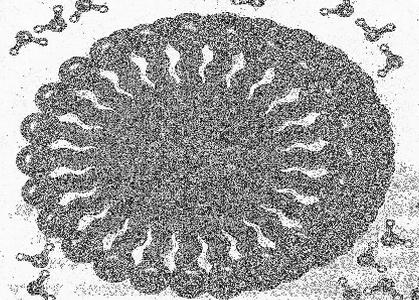

**Micelles**

All hydrophobic groups are sequestered from water; no highly ordered shell of H₂O molecules is present, and entropy is increased.
