Introduction

The Gordon-  
Schaefer  
Model

Small Pelagic  
Fish

Optimal  
solutions

Conclusions

In the 50's, the economic theory of common-property fishery was developed by H.S. Gordon thought an equilibrium analysis of a simple dynamics (Gordon-Schaefer model):

$$\dot{x}(t) = F(x(t)) - h(t),$$

where  $x(t)$  is the fish stock level at time  $t$ ,  $h(t)$  is the harvesting (typically  $h(t) = u(t)x(t)$  with  $u(t)$  the fishing effort) and  $F$  is the species biological growth function.

$F$  is usually assumed strictly concave and twice continuously diff. It is also assumed the existence of a saturation constant  $K > 0$  satisfying  $F(0) = F(K) = 0$  and  $F(x) > 0$  for all  $x \in ]0, K[$ .

For instance, Logistic function:

$$F(x) = rx \left(1 - \frac{x}{K}\right)$$

# Study of Sustainable Equilibriums

Gestión de  
Recursos  
Pesqueros

Héctor Ramírez

Introduction

The Gordon-  
Schaefer  
Model

Small Pelagic  
Fish

Optimal  
solutions

Conclusions

We focus on sustainable equilibrium representing exploitation strategies:

$$0 = F(x^*) - h^*$$

So, we are interested in choosing  $x^*$  so that the benefit (harvesting) is the largest possible. This leads to chose:

$$x^* \text{ maximizing } F \quad (\text{that is } F'(x^*) = 0)$$

The respective  $h^* = F(x^*)$  is called the maximum sustainable harvesting (or yield).

# Study of Sustainable Equilibriums

# Optimal Fishery Management

Gestión de  
Recursos  
Pesqueros

Héctor Ramírez

Introduction

The Gordon-  
Schaefer  
Model

Small Pelagic  
Fish

Optimal  
solutions

Conclusions

For our first fishery management problem we consider a **sole owner** who manages the fishery.

Additionally, we assume the following:

- The harvesting effort  $h(t)$  is proportional to the fishing effort  $e(t)$  and to the biomass  $x(t)$ , that is,  $h(t) = u(t)x(t)$ .
- We assume the sole owner is price taking, i.e. the price per unit of biomass  $p$  is constant (and known) over time.
- There are no costs; there is no rate of discount.
- There are no storage possibilities. Current sales and profits only depend on current harvesting.
- The price and all constants are known with certainty.
- The fishery is exploited in a given (fixed) period of time  $T$ , and initially it was not exploited.

Conclusions

- Schaefer (linear) technology of harvesting  $H(t) = u(t)x(t)$  does not seem appropriate for small pelagic fisheries such as sardine, herring, Peruvian anchovy and **Chilean Jack Mackerel (jurel)**:

- We have empiric reasons in order to propose the harvesting function  $H(t) = u^\alpha(t)x^\beta(t)$  with  $\alpha + \beta \geq 1$ ,  $\alpha, \beta \geq 0$ .
- The interest in such a model is based on statistics evidence obtained for pelagic fisheries in Chile (Peña & Basch 2000).

Small Pelagic  
Fish

Optimal  
solutions

Conclusions

- We consider  $N$  players (e.g.  $N$  types of fishing firms) in competition for the same fishery resource (say a single fish stock).
- The harvesting technology is given for each firm by a Cobb-Douglas function:

$$H_i(t) = u_i^\alpha(t)x^\beta(t),$$

where  $u_i(t)$  is the firm  $i$ 's fishing effort (normalized).

- We propose a differential game that explain the interaction between different firms exploiting a pelagic fishery and we study the social planner problems associated.
- We are interested in the behavior of the solutions of our problem for small values of  $\beta$ .

Under the (additional) assumptions:

- Cooperative harvesting are not feasible because of high monitoring costs.
- We assume price taking firms, i.e. the price per unit of biomass  $p$  is constant (and known) over time and independent of industry harvesting.
- At every period  $t$ , each firm  $i$  choose its own fishing effort  $u_i(t)$ .
- There are no fixed costs. Total harvesting cost for  $i$  is equal to  $c_i u_i$ , where  $c_i$  is the constant average of fishing effort for the  $i^{th}$  firm.
- There are no storage possibilities. Current sales and profits only depend on current harvesting.
- Individual firms behave as intertemporal profit maximizing agents.

Conclusions

We consider  $N$  **symmetric** player, that is, all firms have the same technology:  $r_i = r$  and  $c_i = c$ , for all  $i = 1, \dots, N$ .

We set  $u(\cdot) \in [0, \bar{U}]$  as the control variable for the social planner.

The social planner optimization problem is the following

$$\max_{u(\cdot)} N \int_0^{\infty} e^{-rt} (pu^{\alpha}(t)x^{\beta}(t) - cu(t))dt \quad (P_{SP})$$

subject to:

$$\begin{aligned}\dot{x}(t) &= F(x(t)) - Nu^{\alpha}(t)x^{\beta}(t) \\ x(0) &= x_0 > 0\end{aligned}$$

Notice that in this case  $u_i = u$ .

From now on we suppose that  $\alpha + \beta = 1$ .

Conclusions

**Pontryaguin's Principle** leads to the following system for the state  $x$  and adjoint state  $\lambda$ :

$$\begin{cases} \dot{x}(t) = \varphi_1(x(t), \lambda(t); \beta) \\ \dot{\lambda}(t) = \varphi_2(x(t), \lambda(t); \beta); \\ x(0) = x_0 \end{cases} \quad (\text{PP})$$

where

$$\varphi_1(x, \lambda; \beta) := \begin{cases} F(x) & \text{if } \lambda \geq p \\ F(x) - N\phi^{1-\beta}(\lambda)x & \text{if } \lambda < p, \end{cases}$$

$$\varphi_2(x, \lambda; \beta) := \begin{cases} \lambda(r - F'(x)) & \text{if } \lambda \geq p \\ \lambda(r - F'(x)) - \beta N\phi^{1-\beta}(\lambda)(p - \lambda) & \text{if } \lambda < p, \end{cases}$$

and

$$\phi(\lambda) := \left( \frac{(1 - \beta)(p - \lambda)}{c} \right)^{\frac{1}{\beta}}$$

# Some Comments

- We need to impose condition  $F'(0) > r$  to ensure that the stationary solution  $x^*(\beta)$  will be strictly positive.
- Otherwise, it would be optimal to fully deplete the resource  $x$  and thereby being able to invest the obtained harvesting profits at the market return  $r > 0$ .
- From the above theorem, relation  $\lambda^*(\beta) \uparrow p - c$  when  $\beta \downarrow 0$  (i.e.  $\ln \left( \frac{F(\bar{x})}{N\bar{x}} \right) + 1 > 0$ ) is the solution which is consistent with economic intuition.
- This implies, on the one hand, an upper bound on the number of firms  $N$ , for given values of  $F$  and  $r$ ,
- and, on the other hand, a lower bound on the discount rate  $r$  (its upper bound is given by the condition  $F'(0) > r$ ), for given values of  $N$  and  $F$ .

The Gordon-  
Schaefer  
Model

Small Pelagic  
Fish

Optimal  
solutions

Conclusions

- We have studied a Cobb-Douglas type harvest function based on empirical works in fishery management.
- The case  $\alpha, \beta \geq 0$  and  $\alpha + \beta = 1$  has been analyzed.
- In particular, we have established the behavior of the stationary couple of the Pontryaguin system when  $\beta \rightarrow 0$ .
- The possibility of approaching a fishing collapse outcome has been studied via the phase diagram analysis of the Pontryaguin system.

solutions

Conclusions

- It is interesting to study the case when  $\alpha > 1$  and  $\beta \geq 0$ .
- To study the Nash equilibriums of our model<sup>2</sup>.
- To study the sensitivity of these Nash equilibriums with respect to changes in the parameters  $\alpha$  and  $\beta$ .
- An interesting but complex goal is the study Stackelberg's equilibriums and their dependence on  $\beta$ .
