# Liskov substitution principle

---

Initially introduced in 1987 by Barbara Liskov

Formulated in 1994 with Jeannette Wing as follows:

*Let  $q(x)$  be a property provable about objects  $x$  of type  $T$ .  
Then  $q(y)$  should be true for objects  $y$  of type  $S$  where  $S$  is a  
subtype of  $T$ .*

void f (B object) {  
    ...  
}
```

# Liskov principle vulgarized

---

```
void f (B object) {  
    ...  
}  
    if f(new B())  
    behaves correctly, f  
    (new D()) has to  
    correctly behave as  
    well
```

# Fragile class

---

```
void f (B object) {  
    ...  
}  
    if f(new B())  
    behaves correctly and  
    f(new D()) not, then  
    we say that D is fragile  
    in the presence of f
```

### Abstract

The notions of class, subclass and virtual procedure are fairly well understood and recognized as some of the key concepts in object-oriented programming. The possibility of modifying a virtual procedure in a subclass is a powerful technique for specializing the general properties of the superclass.

In most object-oriented languages, the attributes of an object may be references to objects and (virtual) procedures. In Simula and BETA it is also possible to have class attributes. The power of class attributes has not yet been widely recognized. In BETA a class may also have *virtual class attributes*. This makes it possible to defer part of the specification of a class attribute to a subclass. In this sense virtual classes are analogous to virtual procedures. Virtual classes are mainly interesting within strongly typed languages where they provide a mechanism for defining general parameterized classes such as set, vector and list. In this sense they provide an alternative to generics.

Although the notion of virtual class originates from BETA, it is presented as a general language mechanism.

### 1 Introduction

The notions of class and subclass are some of the key language concepts associated with object-oriented pro-

gramming. Classes support the classification of objects with the same properties, and subclassing supports the specialization of the general properties. A class defines a set of attributes associated with each instance of the class. An attribute may be either an object reference (or just reference for short) or a procedure.

In a subclass it is possible to specialize the general properties defined in the superclass. This can be done by adding references and/or procedures. However, it is also possible to modify the procedures defined in the superclass. Modification can take place in different ways. In Simula 67 [4] a procedure attribute may be declared virtual. A virtual procedure may then be redefined in a subclass. A non-virtual procedure cannot be redefined<sup>1</sup>. This is essentially the same scheme adapted by C++ [16] and Eiffel [13]. In Smalltalk [6] any procedure is virtual in the sense that it can be redefined in a subclass, and even the parameters of a procedure may be redefined.

In BETA [8] a virtual procedure cannot be redefined in a subclass, but it may be further defined by an *extended definition*. The extended procedure is a "sub-procedure" (in the same way as for subclass) of the procedure defined in the superclass. This implies that the actions of a virtual procedure definition are automatically combined with the actions of the extended procedure in a subclass. This is the case for all levels of subclasses that further defines a virtual procedure. In Smalltalk and C++ it is the responsibility of the programmer to combine a redefined virtual procedure with the corresponding virtual procedure of the superclass. This is of course more flexible, since the programmer can ignore the procedure in the superclass. However, it is also a potential source of error since the programmer may forget to execute the virtual procedure from the superclass.

Using the terminology from [18] a class in BETA

<sup>1</sup>In Simula a subclass may declare a new procedure with the same name as a procedure defined in a superclass. This does not have the effect of a redefinition as in Smalltalk.

```
Window: class Stream
  (# UpperLeft,LowerRight: @ Point;
   Label: ~ Text;
   Move: proc (# ... #);
   Display: virtual proc (# ... #);
  #)
```

Figure 2: Example of class declaration

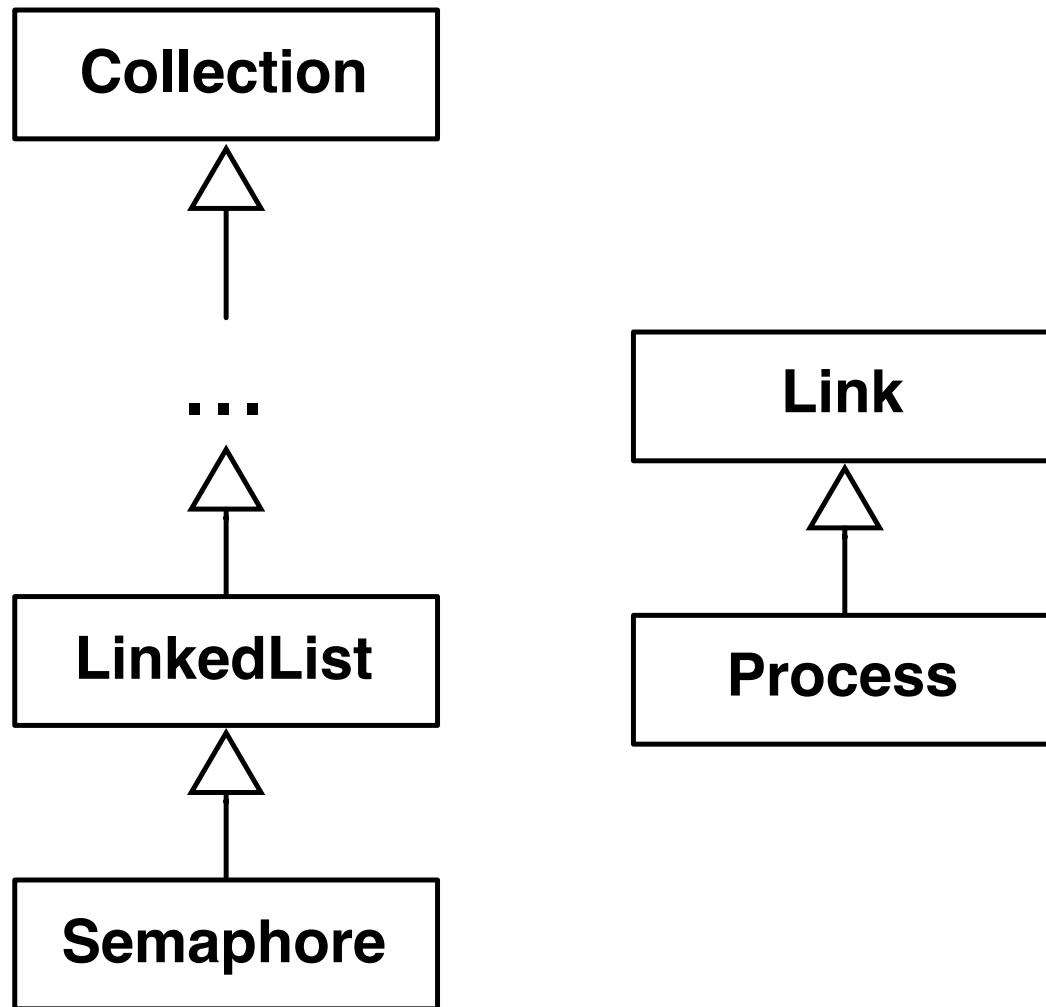

“In Figure 2 an example of a class is given. Class Window is described as a subclass of class Stream. ...”

```
Window: class Stream
  (# UpperLeft,LowerRight: @ Point;
   Label: ~ Text;
   Move: proc (# ... #);
   Display: virtual proc (# ... #);
  #)
```

Figure 2: Example of class declaration

“In Figure 2 an example of a class is given. Class Window is described as a subclass of class Stream. ...”

*Do you think a window can be considered as a stream?*

Probably a semaphore can be seen as a collection, but is it worth subclassing `LinkedList` in that case?

# Presentation of AWT

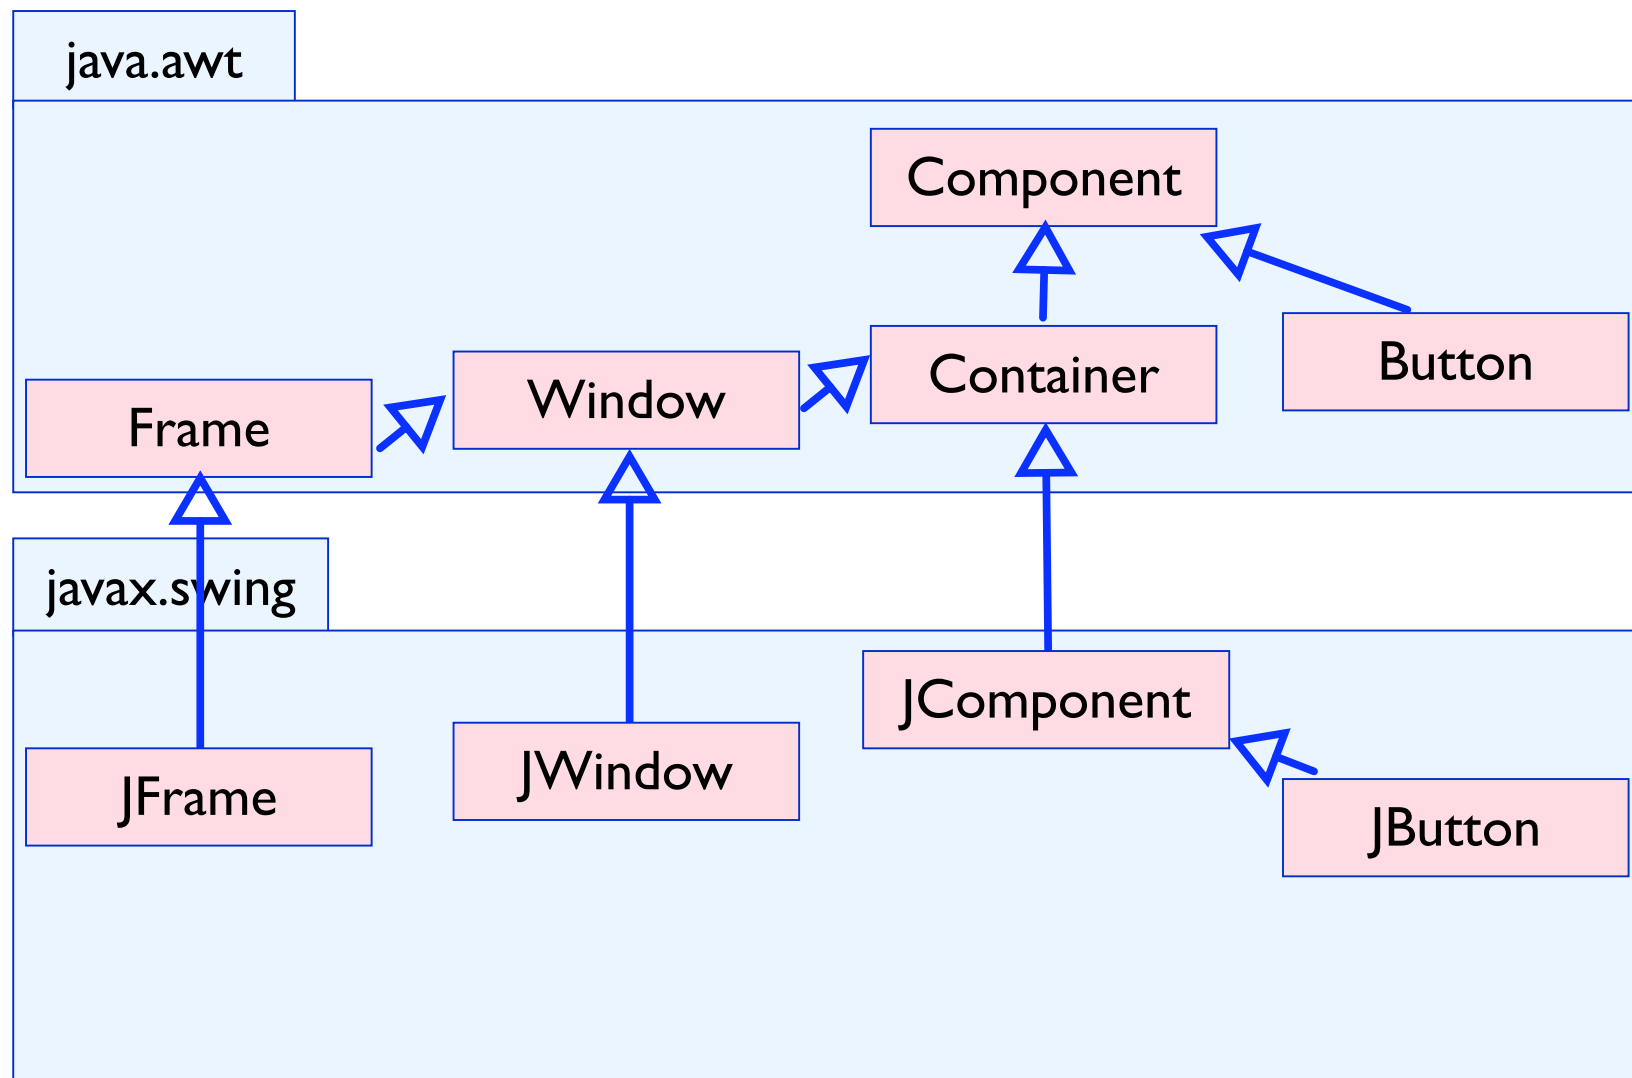

In the AWT framework:

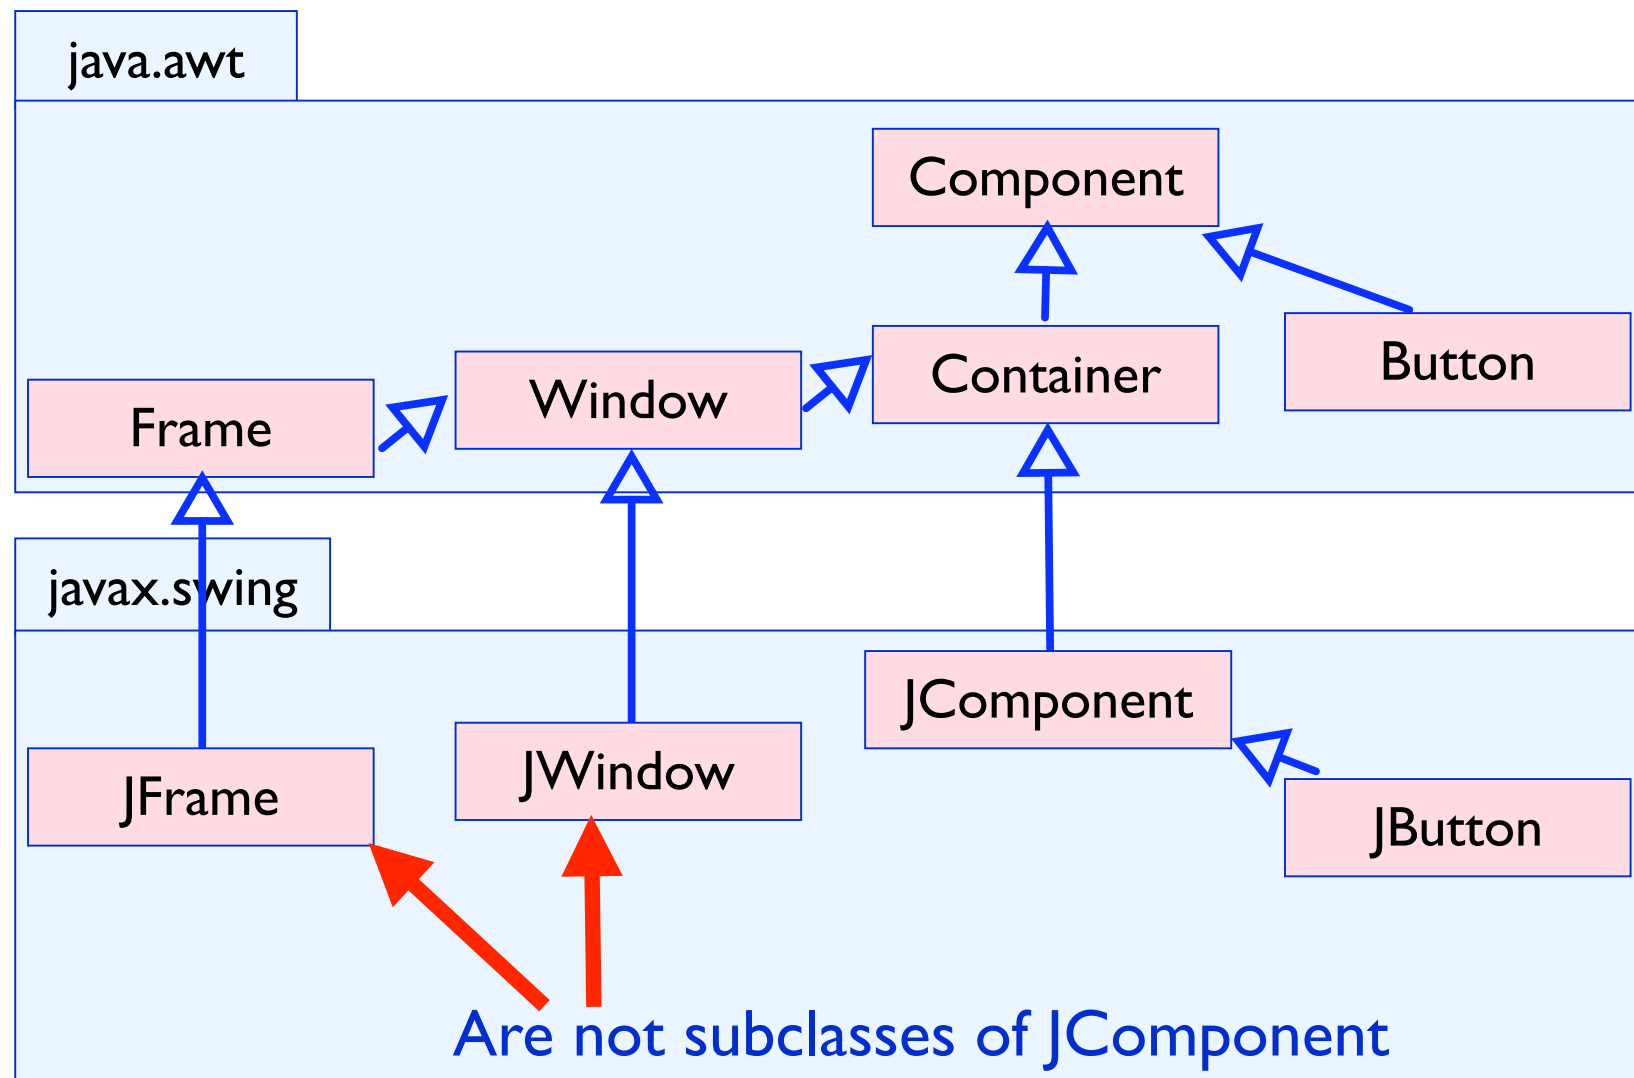

Widgets are components (i.e., inherit from `Component`)

A frame is a window (Frame is a subclass of `Window`)

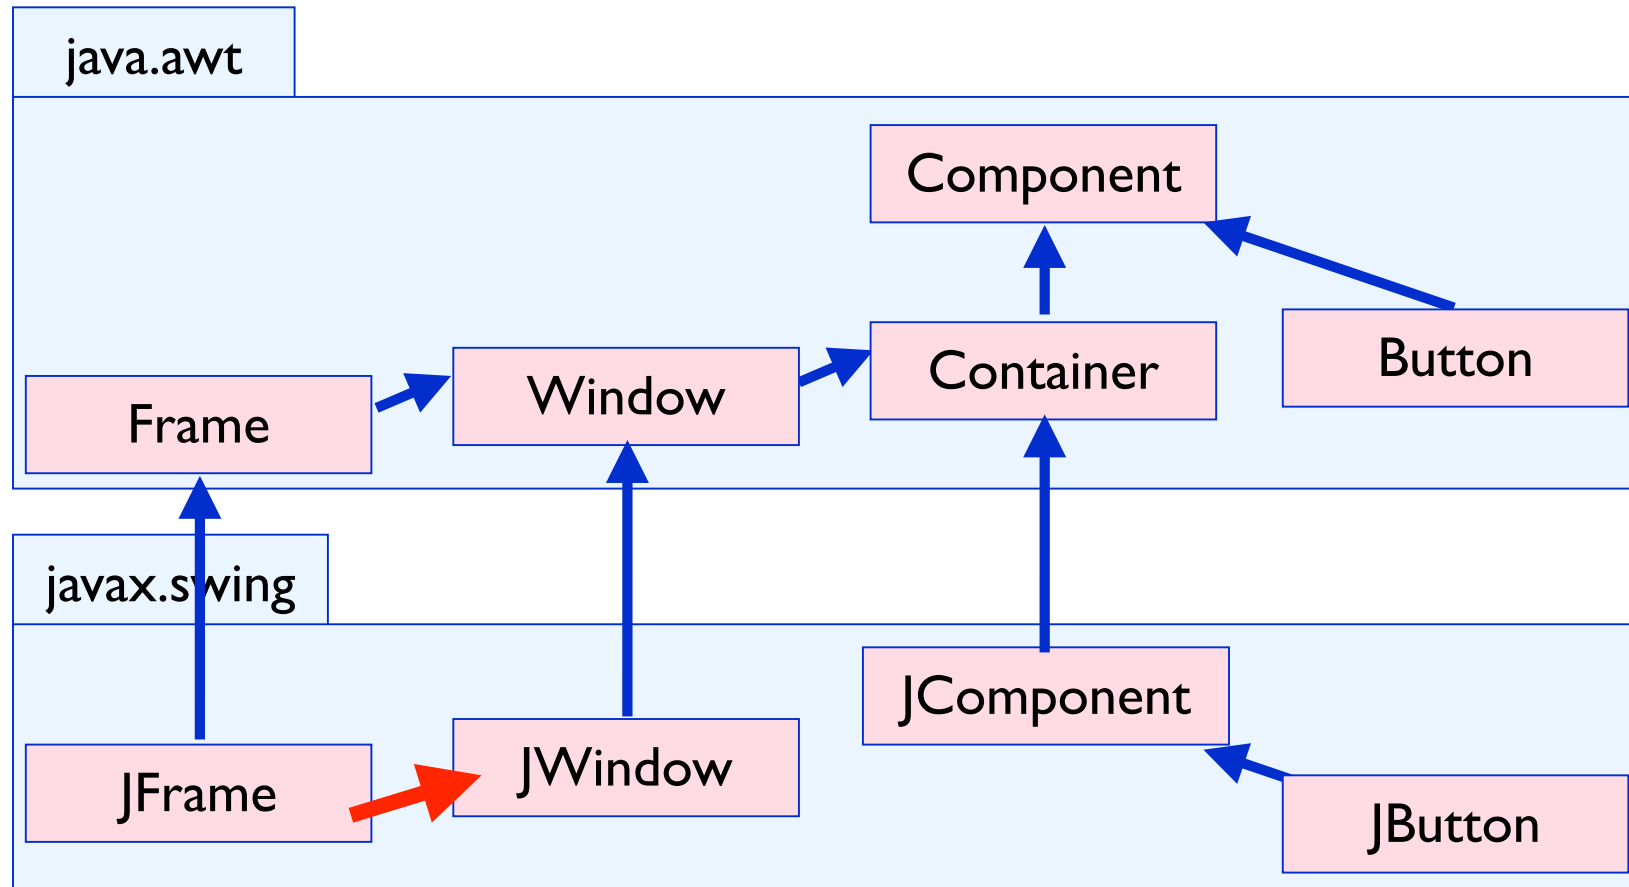

# Swing at the top of AWT

# Problem #1: Broken Inheritance

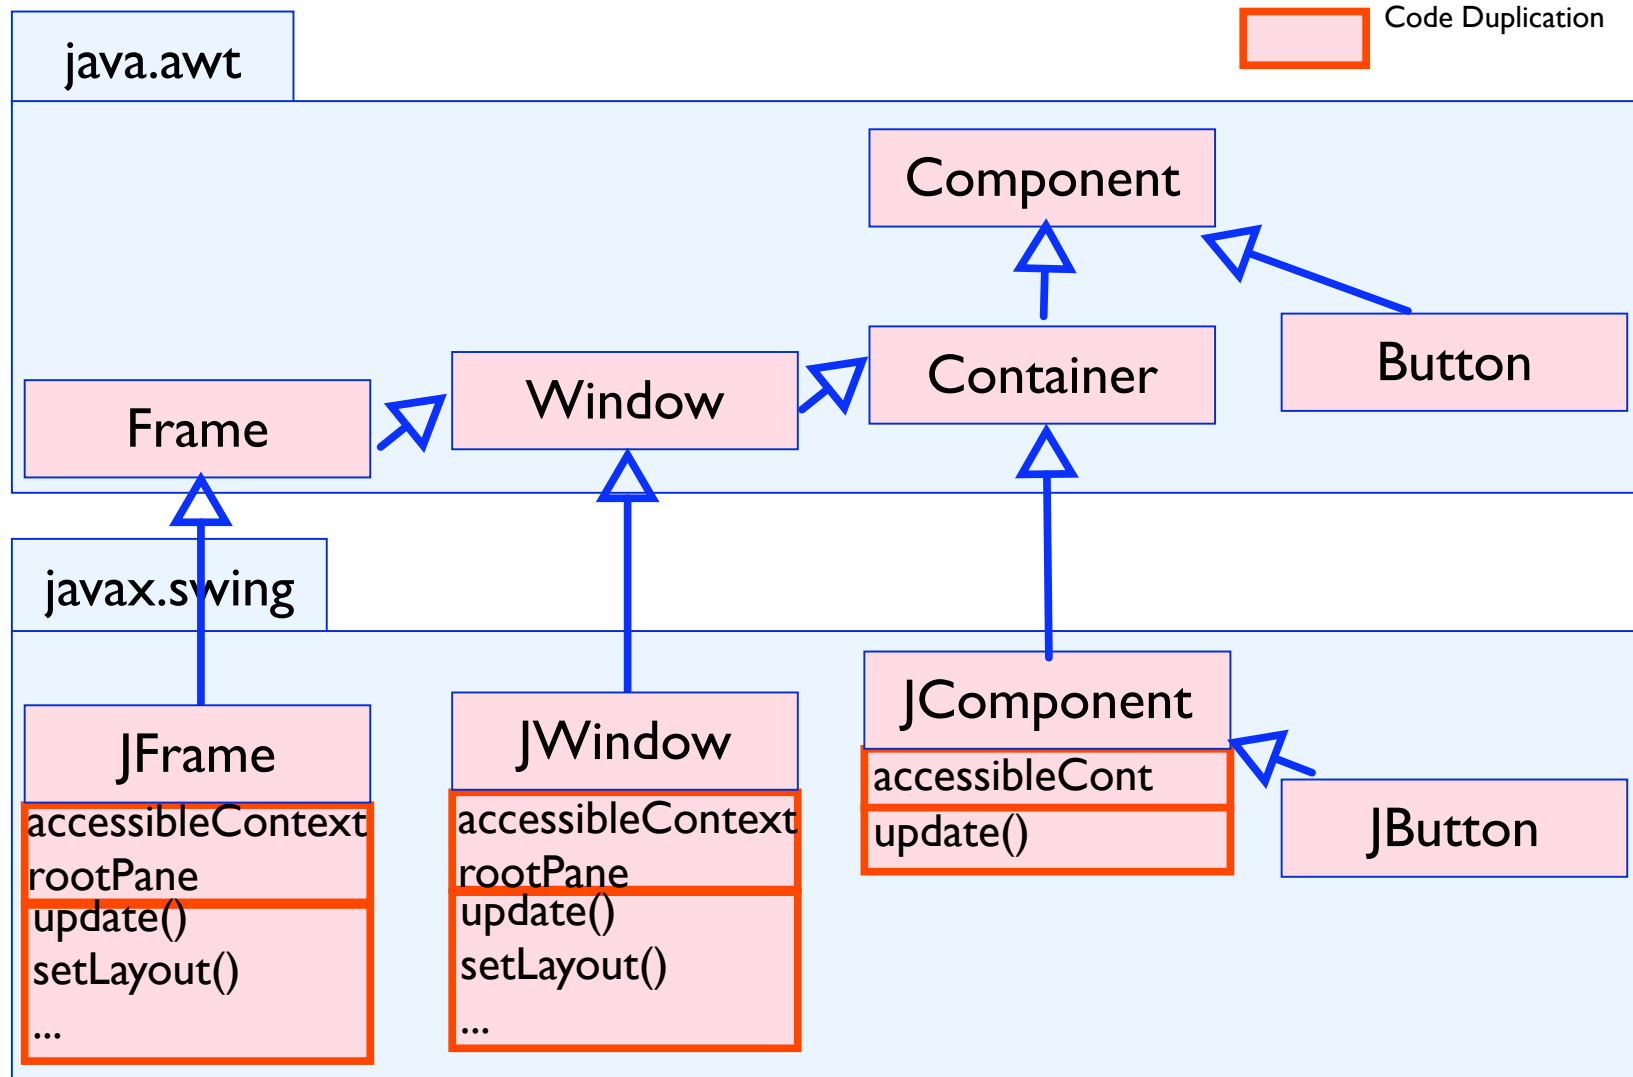

# Problem #1: Brocken Inheritance

Missing inheritance link between JFrame and JWindow

# Problem #2: Code Duplication

# Problem #3: Explicit Type Checks and Casts

```
public class Container extends Component {  
    Component components[] = new Component [0];  
    public Component add (Component comp) {...}  
}
```

```
public class JComponent extends Container {  
    public void paintChildren (Graphics g) {  
        for (; i>=0 ; i--) {  
            Component comp = getComponent (i);  
            isJComponent = (comp instanceof JComponent);  
            ...  
            ((JComponent) comp).getBounds();  
        }  
    }  
}
```

# Supporting Unanticipated Changes

---

AWT couldn't *be enhanced* without risk of *breaking* existing code

Swing is, therefore, *built on the top* of AWT using *subclassing*

As a result, *Swing is a big mess internally!*

# Why do we care to have a messy Swing ?

---

Swing appeared in 1998, and *has not evolved since!*

*Swing is too heavy* to be ported to PDA, cellphones, ...

SWT is *becoming* a *new standard*.

*Either a system evolves, or it is dead.* [Lehmans74]
